## ORIGINAL LECTURES.

A COURSE OF CLINICAL LECTURES  
ON  
DISEASES OF THE KIDNEY.

By GEORGE JOHNSON, M.D. F.R.C.P.

[Physician to King's College Hospital.(a)]

## LECTURE I.—INTRODUCTORY.

If you consult the returns of the Registrar-General for the purpose of ascertaining the relative mortality from diseases of various organs, you will be apt to conclude that diseases of the kidney are either of infrequent occurrence, or easily curable—at any rate that they are not often fatal; yet such an estimate of the frequency and fatality of renal diseases would certainly be a most erroneous one. It very commonly happens that in a death certificate mention is made only of that particular disease or morbid process which has been the immediate cause of death, as, for instance, apoplexy, coma, paralysis, convulsions; or, again, with respect to diseases within the chest, bronchitis, pneumonia, pleurisy, hydrothorax, pericarditis, endocarditis; and, in the abdomen, ascites, peritonitis, muco-enteritis, diarrhoea, etc.

Now, each of the diseases which I have enumerated, not to mention a number of others, is not unfrequently only the last link in a chain of morbid processes, the first link, the starting point and origin of which is disease of the kidney; so that, while the mere registrar would certify that the cause of death in a particular instance has been coma or apoplexy, the pathologist and the practical physician would trace back the coma to uræmic poisoning, the result of degeneration of the kidney.

The subject of renal pathology owes much of its interest and much of its practical importance to the fact, that disease of the kidney is often associated, either as cause or as consequence, with many of the commonest and most fatal diseases.

FIG. 1.

Plan of the minute structure of the kidney. *a*. Artery, sending an afferent branch, *a'* to *m*, the Malpighian body. *ef*. Afferent vessel. *p*. The plexus of capillaries between the tubes. *v*. The vein. *t*. The uriniferous tube. *c*. The capsule of the Malpighian body.

You will not long pursue your clinical studies without finding abundant illustrations of this statement. Cases of renal disease are always to be found in the medical wards, and you

cannot fail to be interested in the many important problems which they present for our solution.

Before I direct your attention to the cases which have recently been under treatment in the Hospital, I must briefly allude to certain facts which have a general bearing upon the whole subject of renal disease. And, first, with regard to the minute structure of the kidney, I may perhaps assume that you are familiar with this subject, a knowledge of which is essential for the right appreciation of some of the most interesting and important features of renal diseases.

The diagram before you will serve to remind you of the chief points in the minute anatomy of the kidney, for a knowledge of which we are indebted to Mr. Bowman. You see that the uriniferous tube ends or commences in a globular expansion, which forms what is called the capsule of the Malpighian body. The artery sends off a terminal branch, the afferent vessel, which pierces the capsule and so passes within the globular dilatation of the tube. In this cavity it breaks up into a capillary tuft, the vessels of which re-unite into a single vessel, the efferent vessel, which passes out through the capsule, and then enters a capillary plexus lying outside the uriniferous tube among its coils and convolutions. The course of the circulation through the kidney, then, as indicated by the arrows in the diagram, is from the artery, through the afferent vessel, into the Malpighian capillaries, thence through the efferent vessel into the inter-tubular plexus, and from this into the renal vein. Then you will remember that the uriniferous tubes are lined by cells which have all the characters of true glandular epithelium, as seen in the second diagram.

FIG. 2

Portion of uriniferous tube, composed of basement membrane, with a lining of epithelial cells. The clear canal within the layer of cells is equal to about half the diameter of the tube.

Within this lining of cells there is a clear canal in the central part of the tube. Of this canal I shall presently have to speak in connexion with some of the varieties of tube-casts which occur in the urine.

In the course of the present session, I shall probably have the opportunity of giving you some practical illustrations of most of those morbid conditions of the kidney which are commonly included under the term Bright's disease. You will perhaps ask, as many have done before, what is Bright's disease? To this question I must reply by telling you first, what is *not* Bright's disease. There are certain diseases of the kidney which, by common consent, are excluded from the category of morbid changes, to which the term Bright's disease is applied. These are—1. Diseases originating in local and mechanical injuries—stone in the kidney or bladder; stricture of the urethra; blows on the loins producing abscess, etc. 2. Tubercle, cancer, and hydatids in the kidney. These forms of disease were all recognised and described before Dr. Bright published his "Medical Reports." And now with respect to Bright's disease: It had long been known that dropsy and renal disease were occasionally associated; it was also known that some dropsical patients had albuminous urine. Dr. Bright's great merit and originality consisted in this, that he pointed out the connexion between these three conditions—dropsy and albuminous urine during life with peculiar morbid changes in the kidney discoverable after life. Dr. Bright described and figured these morbid changes, showed with how great frequency they occur, with what numerous and important secondary diseases they are commonly associated, and thus, like Dr. Livingston in Southern Africa, he opened up the great field of renal pathology, which previously had been, for all practical purposes, an almost unknown region.

(a) The Lectures on Renal Diseases, an abstract of which it is here proposed to publish, have been delivered at various times to the clinical class in King's College Hospital. In arranging them for publication I have made some modifications and additions, but for the convenience of having a well-defined audience before the mind's eye, I have throughout supposed myself to be addressing those to whom the lectures were originally delivered.

These morbid conditions of the kidney being known, it remained to give them a name, and various names have been proposed. Rayer uses the term "albuminous nephritis," implying the notion of an inflammation of the kidney, attended with the secretion of albuminous urine. Christison calls the disease "granular degeneration," though it is an admitted fact that some of the most characteristic Bright's kidneys have no appearance of granulation. Then it has been and is still the practice to designate these morbid states of the kidney by the name of the distinguished Physician who discovered them.

Now, the term "Bright's disease" seems to involve the idea of unity, and some pathologists have attempted to prove that this is a true expression of the fact,—that all the various appearances in the kidney which have been described and figured by Dr. Bright are the result of a single morbid process in different stages and degrees of intensity. I shall have no difficulty in demonstrating by the aid of the clinical history of the cases which will come under our observation that this notion of the unity of "Bright's disease" is erroneous in theory and mischievous in practice. In the meantime I beg you to bear in mind that the term "Bright's disease" is not strictly and exclusively applicable to any *single* morbid change in the kidney, but that under this general term are included *several forms of acute and chronic disease, which are usually associated with an albuminous condition of the urine, and frequently with dropsy and various other secondary diseases.*

According to this definition of the term, a patient who has general dropsy with albuminous urine as a consequence of scarlet-fever, may be said to have acute Bright's disease; while one who, after a long course of intemperance, is found to have the kidneys reduced to half their normal size, and another who, after suffering several months from dropsy, has his kidneys much enlarged and fatty, present examples of two different forms of chronic Bright's disease.

Now, I expect to be able to show you in the course of a few months of clinical practice that the various pathological states of the kidney may be detected during life by a comparison of the history of each case with a chemical and microscopical examination of the urine, with scarcely less certainty than when the diseased organ is exposed to view after death. And you will not fail to appreciate the practical importance of this when you consider how much the prognosis and even the treatment of renal disease must be influenced by a precise diagnosis; inasmuch as some morbid conditions of the kidney are far more serious than others, either being originally and essentially more formidable in character, or indicating a more inveterate and advanced degeneration of tissue.

Let me now impress upon you the fact, that all the forms of Bright's disease have this in common: that the essential part of their morbid anatomy is in the interior of the convoluted uriniferous tubes, and that the epithelial or gland cells which line those tubes are the first parts to suffer change. The morbid conditions of other tissues, although of considerable interest, more especially those affecting the blood-vessels, are second in time and importance. It is in the performance of its function as a great excretory gland that the kidney becomes the subject of Bright's disease; and the disease in question has its origin in those epithelial cells of the convoluted tubes which constitute the essential part of the kidney as a glandular organ.

While the gland-cells are undergoing morbid change, there usually occurs from the vessels of the Malpighian tuft (see fig. 1) an effusion of albumen and fibrin into the cavity of the tubes. These effused products mingle with the natural secretion of the kidney, and give rise to two important signs of the existence of Bright's disease. 1st, An albuminous condition of the urine, which renders it coagulable by heat and nitric acid; and, 2nd, the appearance of cylindrical moulds or casts of the uriniferous tubes, discoverable on a microscopical examination of the urine. These casts are composed of fibrinous material, which having coagulated in the cavity of a tube has subsequently escaped with the urine. The different appearances presented by these tube-casts afford most valuable indications of the condition of the tubes in which they have been moulded, and greatly aid the diagnosis between the various forms and stages of Bright's disease.

As an illustration of this part of the subject, let me direct your attention to this drawing (fig. 3), in which you see represented some wax-like clear casts, some of which are about twice the diameter of the others. The small sacs have been

moulded in tubes which retain their epithelial lining (see fig. 2), and their diameter corresponds with that of the clear canal which is left within the layer of cells. The larger casts,

FIG. 3.

Large and small wax-like fibrinous casts of the tubes of the kidney, from the sediment in albuminous urine.

which have the full diameter of the uriniferous tubes, and a remarkably sharp outline, have been formed in tubes which have lost their epithelial lining, and with it their proper secretory function. These large casts then indicate a more serious degeneration of the tubular structure than the small ones. They are often combined in the urine of the same patient, but the existence of a large proportion of the full-sized wax-like casts in the urinary sediment is usually a sign of serious import.

In my next lecture I shall bring to your notice some cases of Bright's disease which have lately been under treatment in the Hospital.

## ORIGINAL COMMUNICATIONS.

### THE PHYSIOGNOMY OF INSANITY.

By JOHN CONOLLY, M.D. D.C.L.

Consulting Physician to the Hanwell Asylum.

#### NO. 1—RELIGIOUS MELANCHOLY.

THE external characters of various bodily diseases must have attracted the attention of practitioners in the remotest era of the history of medicine; and the outward signs and expression of inward suffering, and even of organic changes within the body, have never subsequently been overlooked by practical Physicians and Surgeons. Some of these are so obvious, that no one possessed of the ordinary senses can fail to recognise them; others are only to be read after long experience. But as there is much difficulty in putting into words the shades of expression and modifications of attitude which convey this sort of knowledge to the practised observer, there appear to be few works, at least in the English language, which treat of it in connexion with the general subject of Medical Diagnosis. It has been, indeed, chiefly, and almost exclusively, cultivated and enriched by the late Dr. Marshall Hall, whose work on Diagnosis is said to have been commenced when he was a student in Edinburgh, and whose writings on Symptomatology (*Cyclopædia of Practical Medicine*, vol. iv. p. 105) contain, in a condensed form, much that deserves the careful attention of the student and of the young practitioner. A very valuable Manual of Diagnosis has been published, quite recently, by Dr. Barclay, in which an extraordinary quantity of knowledge is compressed into a most reasonable and readable form.

How strongly the lineaments of disease are imprinted in the face is well known to every one who ever dwelt with interest on the aspect of a patient advanced in phthisis pulmonalis; where the bright eyes, the deep carving of the orbits and temples, the pearly facial colour, and the fatal bloom, combine to exclude every shadow of hope from the prognosis. Scarcely less positive facial exposition exists, although less easy to be read at a glance, in certain forms of dropsy. The protruded eye and distressed look of the asthmatic, or of one labouring under heart-disease, and certain alterations of colour attendant on some forms and stages of dyspepsia, and in several diseases of the stomach, the liver, the spleen, and the intestines, and also of the kidneys and bladder, are well known to careful Physicians. In some of these affections, in which there are paroxysms of agony which overcome the constitutional fortitude or habitual cheerfulness, the change of expression from cheerfulness to misery becomes distressingly eloquent. Throughout the long course of an attack of fever, a daily journal of the patient's condition may be read in his face and his attitude; well known to all who have anxiously watched the life of some valued man struggling, week after week, and day and night, against all the trying changes of this formidable malady; and who, when recovery has begun to dawn, have rejoiced to see equally clearly written, in the calmer features and easier position, the happy commencement of convalescence.

The peculiar expression and the general external character of mental suffering, or derangement of mind, and of structural changes, or of congenital or induced peculiarities in the brain, have not perhaps excited proportionable regard; not being so frequently presented to the general practitioner, and being, indeed, often extremely difficult to define, even when clearly recognised. The ordinary expression of the passions and emotions is legible enough in every face, and every day. Its exaggeration in those whose reason is beginning to remit its control, and whose wits are just beginning to wander away from the truthful recognition of things, so that hope is unduly indulged, or despondency is overshadowing the thoughts, often escapes that early detection which is so much to be desired, because so important to the well-doing of the patient.

In some busy years, passed for the most part in the long galleries of Hanwell, into which were brought, almost every day, new illustrations of the various forms of insanity; and when nearly every hour was enlivened by incidents which excited both the intellect and the feelings of those engaged in the duties of that noble institution for the lunatic poor; I used frequently to regret the want of the art or of the help of a painter, to enable me to convey to others by pictorial images the strange aspects and facial expressions of mental malady, which were often more forcible than any words that could have been employed. Now and then some friendly artist, interested in such a subject, would take the likenesses of some of the patients, generally of the convalescent, a proceeding which always gratified them.

The beautiful plates appended to Esquirol's great work on *Mental Maladies* had already shown what could be done by the engraver's art to illustrate medical description; and Sir Alexander Morison's volume on the *Physiognomy of Mental Diseases*, containing numerous lithographs, had furnished a curious variety of representations of the same kind. But the expense attendant on any attempts to add to these varieties could not be incurred in an asylum for the poor; and in each of the works mentioned the engravings, being accompanied with too brief a commentary, were, generally speaking, more calculated to produce a temporary interest than to impart important instruction. If Esquirol's life had been prolonged, he would probably have fulfilled his design of publishing a complete work on the physiognomy of the insane, for the illustration of which he had caused very numerous portraits to be prepared. I must gratefully acknowledge that his nephew, M. Mitivié, has most liberally offered to place these at my disposal; but the references to the histories of the cases appear to be either defective or altogether wanting.

Since the time, however, to which I am referring, short as the time is, the new and important discovery of the art of photography, the applications of which are so diversified and valuable, and by which, in the course of a few seconds, the form and fabric of material things are copied and fixed with a fidelity scarcely attainable by graphic skill or by the painter's

art, has endowed the Physicians attached to asylums with the power I wished for; and some of them have so ably exercised it, as to produce copies of nature, possessing a truthfulness and preserving minutiae which could not easily be perpetuated by any of the old methods.

Among those who now preside with so much advantage to the afflicted over the large asylums near London, no one, it is well known, has acquired a greater proficiency in this interesting art than Dr. Diamond, of the Surrey Asylum. His skill has, indeed, been exercised upon many of his friends, who are happily possessed of the intellectual faculties in high perfection, and some of these portraits have been shown in literary circles, and some, contributed to the late exhibition at Manchester, have excited very deserved admiration. This proficiency has also enabled Dr. Diamond to enrich his portfolios with curious portraits of the insane, which are not only truthful as portraits, but revive in those familiar with insane patients the memory of many others whose various forms of mental peculiarity had made their characteristic stamp; thus furnishing representations highly interesting, generally singular and striking, sometimes amusing, sometimes, it must be confessed, awful, but always suggestive of useful thought.

There is so singular a fidelity in a well-executed photograph that the impression of very recent muscular agitation in the face seems to be caught by the process, which the engraver's art can scarcely preserve. This peculiarity seems to produce part of the discontent often expressed when people see the photographic portraits of their friends or of themselves. It gives, however, peculiar value when, as in the portraits of the insane, the object is to give the singular expression arising from morbid movements of the mind; and thus, instead of giving pictures which are merely looked at with idle curiosity, furnishes such as may be studied with advantage; helping the observation of the Medical student, illustrating the lectures of a teacher, and suggesting some not unproductive reflections to all who examine them.

When we contemplate such portraits of the human face, strained or disfigured by the mysterious workings of a disordered brain, some desire naturally arises in us to inquire into the causes, physical or moral, of states so distressing; and our efforts, by every individual and social exertion, to lessen the weight of trial and of grief on those around us can scarcely fail to be stimulated. We are reminded of the havoc ever making—by evil thoughts, evil habits, or evil passions—or by want and distracting care; and seeing how all the beauty of man is worn away by his frailties or his struggles, we become more acutely sensible that all repose of heart has also been wrecked, and the better part of our nature becomes perhaps, even thus reflecting, finely touched, and “to fine issues.”

The engraving presented to the reader in this number is from a photographic portrait of a young woman labouring under religious melancholy. In this form of melancholy there is no mere worldly despondency, nor thought of common calamities or vulgar ruin; but a deeper horror: a fixed belief, against which all arguments are powerless, and all consolation vain; a belief of having displeased the Great Creator, and of being hopelessly shut out from mercy and from heaven. This portrait, therefore, does not reflect the figure of patients so often recognised in asylums, sitting on benches by the lonely walls, the hands clasped on the bosom, the leaden eye bent on the ground, and the unvarying gloom excluding variety of reflection. It represents an affliction more defined. We discern the outward marks of a mind which, seemingly, after long wandering in the mazes of religious doubt, and struggling with spiritual niceties too perplexing for human solution, is now overshadowed by despair. The high and wide forehead, generally indicative of intelligence and imagination; the slightly bent head, leaning disconsolately on the hand; the absence from that collapsed cheek of every trace of gaiety; the mouth inexpressive of any varied emotion; the deep orbits and the long characteristic eyebrows; all seem painfully to indicate the present mood and general temperament of the patient. The black hair is heedlessly pressed back; the dress, though neat, has a conventual plainness; the sacred emblem worn round the neck is not worn for ornament. The lips are well-formed, and compressed; the angle of the jaw is rather large; the ear seems well-shaped; force of character appears

to be thus indicated, as well as a capacity of energetic expression; whilst the womanly figure, the somewhat ample chest and pelvis (less expressed in the engraving than in the photograph) belong to a general constitution out of which, in health and vigour, may have grown up some self-accusing thoughts in an innocent and devout, but passionate heart. For this perverting malady makes even the natural instincts appear sinful; and the sufferer forgets that God implanted them. But the conflict in the case before us is chiefly intellectual. The meditations of that large brain are not employed on worldly cares, nor even on affections chilled, nor temporal hopes broken. They are engaged in religious scruples, far too perplexing for its power to overcome. In the meantime all the ordinary affections, from which consolation might be derived, are shut out. Soon, perhaps, the scruples themselves will appear crimes. To escape future punishment, bodily mortifications must be endured; severe fasts, or some self-inflicted pain. Under these, the bodily strength, usually impaired in the commencement of the attack, becomes further impaired. The digestion becomes feeble, and even the sparest meals occasion suffering. Emaciation takes place; often proceeding to an extreme degree. The uterine functions (for the subjects of this form of malady are usually women), are suppressed. Paroxysms of excitement may occur, with sudden activity in the prosecution of schemes of vaguest import; but with these futile efforts misgivings become mingled. The thought of suicide, often suggested, becomes fixed; and such varied and ingenious efforts are made to carry it into effect as to demand incessant vigilance. Yet, even in this state there may be days in which the mind is tranquillised, and needle-work is resumed, or the music of happier times is played once more. But these gleams are transient. The mind loses its energy; debility invades every function; pulmonary or mesenteric disease supervenes; the limbs become anasarous; and the wretched patient is only relieved by death.

The subjects of this kind of affliction are often highly intellectual, and this seems to endow them with greater latitude of terrible delusions, and with an eloquence in describing them that cannot always be listened to without emotion; seconded as it is by an expression of countenance full of real horror, and significant of the state of utter spiritual abandonment and degradation into which the patient asserts herself to be plunged, without hope of relief on earth or pardon in heaven.

The medical treatment of religious melancholy is often of more import than that which enthusiastic and very well-meaning persons are too much inclined to resort to. Remonstrances, and the perusal of sermons, and of the tracts scattered over too many drawing-room tables, and showered with mischievous, although well-intentioned, activity among the poor,—nay, even the exclusive reading of the Bible and Prayer-book,—must often be refrained from or forbidden. There are states of mind in which the medical man must have courage to exclude these as poisons. The mind must be diverted to more common and more varied subjects, and the bodily health must have the most careful consideration.

These observations apply to all religious sects. The subject of this photograph had left the Protestant faith, and become what is commonly called a Roman Catholic. Her education had not been such as to enable her to reason well on either side, and she became merely wavering and unsettled in her belief. Attention to ordinary matters was neglected; she sat in the attitude shown in the engraving for a long time together; she was negligent of her dress, and occasionally destructive of it. Often she cried out that she was a brute, and had no soul to be saved. Now and then she had a desire to see some minister of religion, either Catholic or Protestant; and soon afterward would refuse to see either, declaring that neither could be useful to her. All this seems to be expressed in the photograph. The medal she wears was given to her by a gentleman connected with the Catholic establishment.

It is unnecessary to say that her case was managed in the asylum with the most prudent caution. She was encouraged to more bodily exertion; and her mental perplexities, not being aggravated by reasonings unadapted to her, gradually died away. She soon began to occupy herself, and became useful in the laundry of the establishment. She was strengthened by quinine. The inactivity of the digestive

canal, so common, or so constant in cases of melancholia, was counteracted by combining the decoction aloes compositum with a tonic; and shower-baths, of half a minute's duration, contributed to restore general bodily energy. Such attacks never yield at once. They come on gradually, and depart slowly. After a residence of ten months in the asylum, this patient became well. It is gratifying to know that she remains well, having now left the institution seven months since.

The change presented by the countenance after recovery from severe mental disturbance is generally remarkable, and sometimes even surprising. In case of acute mania it is singularly marked; and in the particular form of religious melancholy the cheerful smile that supplants the dismal and anxious look of the patient is almost magical. In the case now referred to, whatever there was of meditative or intellectual cast in the face during the period of melancholy, was almost wholly lost when the attack went off. The ample forehead, of course, remained, and the deep orbits; but the eyes, when open, were small and inexpressive, and the mouth seemed to have become common-place. Her whole appearance was, indeed, so simply that of an uneducated Irish girl, that the very neat gown, cloak, and bonnet, in which she was dressed by the kindness of those about her, seemed incongruous and peculiar. A second photograph, taken at that time, possesses, therefore, little interest. In some other instances the metamorphoses effected by malady and recovery may be usefully, and even instructively represented.

#### NOTES OF

### PRACTICE AMONG THE OUT-PATIENTS OF ST. BARTHOLOMEW'S HOSPITAL.

By JAMES PAGET, F.R.S.

Assistant-Surgeon to the Hospital.

THE out-patients' rooms of large hospitals are not places for the minute study of surgical science; but they may provide a kind of useful knowledge which can be got nowhere else, unless in an extensive private or parochial practice. Some of this knowledge (or what seems to be so) I propose to publish in this and a few following papers. It may be they will contain nothing that is not familiar to the majority of those who have much surgical experience; nevertheless, they may be useful to the larger number, whether practitioners or students, who have fewer opportunities of study; and, although the statements made in them may have been chiefly founded on observations among Hospital-patients, yet I have, in nearly every instance, satisfied myself that they will prove true in private practice. If it be objected that the papers are desultory, disorderly, and fragmentary, the answer may be, that these were, unavoidably, the characters of the studies in which they had their origin, and which, if they were in these respects less faulty, they would less truly represent.

#### NO. I.—ON SOME AFFECTIONS OF LYMPHATIC GLANDS.

*A form of Acute Inflammation of Lymphatic Glands* often occurs, in which all the glands of a cluster appear to coalesce in one swelling, involving both themselves and the tissues between and about them, and accompanied with uniform induration, heat, and pain. The local cause of the disease is seldom evident: it is most frequent in those who are enfeebled by previous illness, or by defective food: its most usual seat is in the glands below the angle and base of the jaw, or in those behind and beneath the upper part of the mastoid muscle. In the former situation, the glands swell out to the level of the jaw, or beyond it, and may feel as if adherent to it; in the latter, being bound down by the tough fascia, they are less prominent; but, in both places, they make swellings of remarkable hardness, with a nearly uniform flattish pre-

scenting surface. The integuments over them are usually somewhat oedematous, but not reddened in proportion to the severity of the deeper inflammation.

In the progress of this disease, which is usually accompanied by sharp inflammatory fever, it is common to find one or two small suppurations, as if one gland in the cluster had suppurated, while the rest remained swollen and hard. The finger passing over the diseased part sinks in as it passes on some small yielding spot; there is no distinct fluctuation, but a circumscribed softness.

It will be found, I believe, an excellent rule to puncture this soft place as soon as ever it is detected. Usually, after such an opening, the pain is quickly relieved, and the rest of the swelling gradually subsides, without any extension of the suppuration. The opening may be small (half an inch or less long), but may need to be rather deep. All that seems necessary is the discharge of even a few drops of pus, and then the leaving the part quiet, with warm moist applications over it. If such an opening be not made in due time, extensive suppuration is nearly sure to ensue, and greatly increase the duration and mischief of the disease.

The rest of the treatment of such cases must usually consist in giving bark, warm purgatives (if any), good food, and in applying warm poultices or water-dressing, and fomentations to the inflamed part, both before and after the puncture.

*Suppuration of Strumous Glands.*—The great number of strumous children, that come to out-patients' rooms with slowly suppurating cervical and other lymphatic glands, supply, I believe, evidence enough that the best plan in all such cases is to leave the suppuration to increase till the skin over it is so thin, that one might think that in a day or two spontaneous ulceration would ensue. The thinnest part of the skin should then be punctured with a small knife, so as to make an opening not more than two lines in length. Through this opening the pus should be allowed to flow out slowly: the abscess-walls should on no account be pressed. If the pus will flow in mere drops, it is well; if it stop altogether, no harm will follow. No more should be done than to cover the abscess with a soft poultice or with warm water-dressing, which should be removed twice or three times a-day. The abscess thus treated will slowly empty itself, as the inflamed and stretched skin slowly recovers its elasticity and contractile power; or if the little wound should heal before the emptying, it will in a day or two reopen; or, at the most, the puncture may need to be repeated. The advantage of the plan is, that the punctured skin does not ulcerate or slough, the abscess-wall does not inflame, and recovery ensues without disturbance of the general health, and with a scarcely visible scar. In the great number of cases that I have thus treated, I do not remember to have failed to obtain these advantages. Usually, the healing of the abscess is completed within three weeks,—in strong contrast, as to both time and manner, with the tedious healing and ugly scarring that often ensue when these abscesses are left to open spontaneously, or are opened widely with the knife or caustic.

The internal treatment which I have always employed in these cases when suppuration has taken place (and which, if any, will prevent its occurrence), is the giving of tonics, or iron, and good food. The medicines for children may be, according to the case, from two to five grains of the potassio-tartrate of iron, or from five to ten grains of the liquor cinchonæ, or a drachm of the cod-liver oil, three times a day. The first I think best in ordinary cases, in which the characters of struma are well marked, and not complicated; the second appears best when with struma there is marked debility, drooping, deadly pallor, duskiness; and I think it is a very good plan to give the bark with lime-water: the third seems fittest when great emaciation exists. In all cases it appears useful to give occasional small doses of the hydrargyrum cum creta, with rhubarb or the sesquioxide of iron. I doubt whether iodine does good in any of these cases, unless in combination with iron.

*Strumous Inguinal Glands.*—Among the affections often wrongly classed with the syphilitic, is a form of suppuration in the inguinal glands, which is apt to occur in those that are enfeebled and of strumous constitution. The confusion of it with syphilis is probably due to its often occurring after gonorrhœa; but it is often seen with no such connexion, and when it does follow gonorrhœa, it is often so late after the cessation of the discharge, that we can only ascribe its occurrence to the general debility which gonorrhœa is apt to produce in weakly persons.

The disease may affect the glands both above and below the crural arch, or either of these sets separately; and the feature which most certainly distinguishes it from syphilitic glandular disease is, that the inflammation, which leads slowly to suppuration, appears to involve separately each gland, with its immediate investments. The glands are not collected, as in one inflamed mass; neither is there much external swelling, or much inflammation around the proper substance of the glands; but they lie separately swollen, and commonly the skin over each, though scarcely, if at all, elevated, appears as a separate small red patch. When suppuration ensues, each gland suppurates and opens separately, or with subcutaneous narrow tracks of communication with the rest. Thus, late in the disease, we may see one or both groins, with two, three, or more openings, leading to as many suppurating cavities or tracks extending under comparatively healthy skin.

In all the characters just described, this disease of the inguinal glands bears the admitted marks of usual, but not constant, distinction between syphilitic and strumous inflammation; of the former as leading to suppuration about the glands, the latter to suppuration in them. And, in correspondence with this, the usual characters of strumous inflammations are noticeable; such as the pale rosy redness of the inflamed integuments, the thinness of the pus, the general tardiness of both the suppurating and the healing process.

The best treatment appears to be, when suppuration has not yet ensued, the giving of iodide of iron, in doses of about a drachm of the syrup thrice daily, with occasional aperients, good food, and the constant application of warmth. If the glands have suppurated, each, when the skin is thin or feels undermined, should be punctured with a small knife; and the pus may be allowed to flow out slowly without pressure. The general treatment after puncture may be the same as before; and if the abscess-cavities appear very tardy in healing, lotions of nitrate of silver should be dropped into them, or, if there be sinuses, they should be injected with solution of iodine. Complete rest is not necessary; the general advantage of moderate exercise in the open air is greater than the injury done by moderate movements of the groins.

I know no disease in which the iodide of iron does so much good as in this; and it appears better than any other preparation of either iodine or iron, and better than bark in any form.

*Cancerous Lymphatic Glands.*—Few diseases are so insidious in their early progress as primary cancer in the cervical lymphatic glands. Beginning like an ordinary hypertrophy or chronic inflammation of the glands, it may advance far without exciting much, if any, suspicion of its terrible nature. Then, as the swelling increases, and, if increasing rapidly, becomes softer at its most prominent part and covered with florid skin, the imitation of suppuration may be so close as to deceive the most practised touch. Puncture by mistake may now discover what is going on; but in some cases, it may only prolong the oversight; for suppuration may have taken place in the substance of a cancerous gland. I have even seen repeated collections of pus in a cluster of cancerous glands, emptied by repeated punctures, prolonging the belief that no cancerous disease existed, though other signs of its presence seemed distinct.

I cannot tell how this error of diagnosis may be always avoided; but the following may be useful helps. In patients of middle or older age, all enlargements of cervical glands, that are not evidently inflammatory or sympathetic, should excite some suspicion of cancer. The suspicion should be the greater the older the patient is. It must be increased, if the glands affected are under the upper part of the mastoid muscle, and still more if they are under the middle of the muscle. It is a bad sign when they form a close compact cluster, or when, after puncture, the swelling does not at all subside: and equally bad when the swelling, as it increases, becomes less moveable. The harder the glands are at first, the more they must be feared; and the probability of cancer is greatly increased if the patient loses weight and strength, or is a member of a family in which cancer has occurred.

The difficulty of diagnosis which is here referred to occurs most commonly in cases of primary cancer of the glands; but it may occur also in those of secondary cancer; for the disease in the glands may so predominate over the primary disease in the tongue, mouth, or jaws, that of this the patient may know little and say nothing. All these parts therefore should, in every case, be carefully looked to.

## ON DISLOCATION OF THE CRYSTALLINE LENS.

By W. WHITE COOPER, F.R.C.S.

Ophthalmic Surgeon to St. Mary's Hospital, etc.

DISPLACEMENT or dislocation of the crystalline lens is an occurrence with which ophthalmic Surgeons are familiar, and presents itself under three distinct forms:—spontaneous displacement of the lens, its transparency being retained; similar displacement, the lens being opaque, sometimes ossified; and genuine luxation, the effect of violence.

The lens may be displaced within the eye by violence, which in extreme cases may burst the globe and then the lens may be completely expelled; or, more rarely, may be detained by the yielding conjunctiva, forming sub-conjunctival dislocation.

Those who are in the habit of examining eyes, meet occasionally with instances of the following peculiarity:—The iris may be seen to vibrate, generally after a slight movement, not with a series of undulations, as in synchysis or true tremulous iris, but giving a single stroke forwards and backwards, as if impelled from behind. This is, in reality, the case, the impulse being derived from the lens. The crystalline is retained *in situ*, by the suspensory ligament, a membrane naturally possessing firmness and elasticity; but under certain conditions these properties are lost, and the lens becomes loosened, vibrating under movements of the head or eye. In the first stages there is not necessarily any deterioration of vision, and the consistence of the eye is not perceptibly altered. In some instances the lens is distinctly seen in contact with the iris; the eyes of a lady, a patient of mine, upwards of eighty years of age, show this in a marked degree. The outline of each lens can be distinctly seen, the iris appearing to be stretched over its face, and swinging with the vibrating lens. The sight, however, is wonderfully good, considering her advanced age.

This yielding of the suspensory ligament to the weight of the lens has a tendency to increase, and to lead to its dislocation. There are numerous cases recorded where the transparent crystalline has passed into the anterior chamber(a), and occasionally the patient possesses the power of passing and repassing it through the pupil, as in a case described by M. Sichel, where however the feat was performed once too often, the lens remained in the anterior chamber, and violent inflammation followed: the relatives of the lad refused to allow the lens to be extracted, and though the eye became quiet, it was ultimately destroyed by a second attack. There seems to be occasionally an hereditary tendency to loosening of the suspensory ligament. In the first number of the *Ophthalmic Hospital Reports*, it is mentioned that a mother and her three eldest boys applied at Moorfields for shortsightedness, all having both lenses displaced laterally. Unfortunately no particulars are given of this remarkable group of cases.

A displaced transparent lens may thus be recognised:—The anterior chamber is unusually large, the iris concave, and the pupil generally dilated and motionless; but the most unmistakable characteristic is a peculiar iridescence of a curvilinear form, visible in the anterior chamber and marking the reflection from the margin of the lens; close inspection will detect this body without difficulty. To use an expression applied by more than one patient, the sight is *bothered*, like that of a healthy eye when under the influence of atropine, and the patient usually suffers more or less from neuralgic pains about the brow and temple. As this condition of the suspensory ligament is idiopathic, both eyes are generally affected, one to a greater extent than the other.

I have seen two instances of spontaneous dislocation of the lens. I unfortunately possess no notes of the first; the particulars of the other are as follow:—

*Dislocation of lens into anterior chamber; transparency retained.*—I was consulted by a clergyman in May, 1856, respecting an affection of the eyesight, which caused him much annoyance. He was a tall, spare man, of strumous habit; eyes rather full, irides grey. For some months he had been teased with a puzzled condition of his sight, interfering with his comfort and the satisfactory performance of his

clerical duties. A fortnight previous to my seeing him, his right eye being more than usually uncomfortable, he had rubbed it briskly, whereby the sight was rendered worse than before. "The best idea I can convey of my sight," said he, "is this: perhaps, when bathing, you have opened your eyes under water; my sight is just as the sight is then." At the time of rubbing the eye he felt pain, and this had since more or less annoyed him, taking the form of brow ache.

Whilst this gentleman was speaking to me, my attention was attracted by a brilliant opal-like reflection, perceptible behind the cornea, and close inspection showed that this flowed from the margin of the lens, which lay in the anterior chamber, clear as a piece of crystal. The iris was pressed back by its bulk, the pupil being dilated and motionless; around the lower half of the cornea was a faint pink zone.

The left eye presented another condition; the iris was tremulous, pupil rather contracted, and when the head was leaned forward the iris was manifestly pushed forward, recovering its plane as the head was thrown back.

The lens was loosened, and might be propelled by pressure on the eye into the anterior chamber. I warned him, therefore, on no account to rub it, lest that accident should occur.

I had arranged with this gentleman to investigate carefully the condition of his sight the following day, but unfortunately he was unexpectedly summoned from town, and thus I lost sight of this interesting case.

In the same way that a clear lens becomes luxated from a faulty suspensory ligament, an opaque lens may be displaced, even to the extent of simulating depression of cataract with the needle. Such cases are extremely rare; but a well-marked example was related to me by the late Mr. Dalrymple, and I subsequently saw the patient. It was on the 20th January, 1851, that Mr. Dalrymple gave me the following particulars:—

This gentleman had for fourteen years lost the sight of his left eye, from a fully formed hard cataract. The day but one previously, he had suddenly and without ascribable cause been attacked with acute pain in the forehead, conveying to his mind the idea of an impending fit: but to his amazement he discovered that sight had returned to his blind eye. Mr. Dalrymple had just seen him, and assured me that there was no vestige of cataract, the lens having manifestly sunk. "I told him," said he, "that he was a lucky man, that this strange accident had saved him a hundred guineas, but that he must go home, keep quiet, and act in all respects as if an operation had been performed." The case did perfectly well, and the gentleman recovered good sight.

By one of those coincidences not uncommon, a somewhat similar occurrence presented itself to me on the following day. I had used the needle three times on the eye of Mrs. Austen, a patient at the North London Eye Infirmary, but the pupil was still completely obstructed by a firm yellow nucleus. On the day in question she was cleaning the floor of her room, when suddenly an acute pain shot through her head, and her sight returned. She came at once to me, and I ascertained that the nucleus had sunk behind the iris, it being just visible below the lower margin of the pupil. She was desired to act as if an operation had been performed, and recovered excellent sight.

About the same time a third case of sudden restoration of sight came under my notice. Mr. Dalrymple had performed extraction on the right eye of a member of our Profession, but the pupil a month afterwards was still obstructed by a densely opaque fragment of lens which had remained after the operation. Mr. Dalrymple being ill, I saw this gentleman from time to time, and on entering the room one day was struck by his vivacious look. He requested me to examine his eye, and say what had become of the piece of lens. The pupil was clear. He then stated that the previous morning he was about to seat himself, but from his imperfect sight missed the chair, and fell to the ground, striking his head somewhat violently against the door. For a minute he was stunned, but on recovering consciousness, discovered to his great satisfaction that sight had returned. The concussion, in fact, had displaced the opaque body and rendered unnecessary a needle operation which was contemplated.

In the majority of cases which have been described, the lens, influenced by its own gravity, has sunk; in those now to be considered, which are always traumatic, the displacement is either upwards, or to the side, usually the inner;

(a) See cases by a most able Surgeon, M. Recordon, of Lausanne, *Ann. d'Oculistique*, tome xxviii.

though in rare instances, of which one will be mentioned, it may descend. When a blow is inflicted on the eye, the globe will be compressed between the impinging force and the hard walls of the orbit; the soft cushion of fat behind the eye tends to diminish materially the force of blows falling directly on the front of the eye, and the brow further protects it; still terrible injuries follow blows from the small hard ball used in rackets and tennis, and I am told that dislocation of the lens is quite common among those confined in the debtors' prisons, where the games in question fill up the great part of their time. In pugilistic combats, on the other hand, where the weightiest blows are aimed at the eye, it is most rare to find the globe burst or the lens displaced. Indeed, in the cases which I have seen, the accident has generally befallen some unlucky peacemaker, who was trying to separate the combatants, and received the blow unexpectedly and sideways.

A blow delivered in this direction may cause rupture of the sclerotic and conjunctiva, and loss of the lens, or the lens may be retained by the loose conjunctiva; the sclerotic almost always gives way either at the upper part, or towards the inner side, and the rupture takes place just beyond the junction with the cornea; subconjunctival dislocation externally is extremely rare, it being difficult to inflict a blow in such a direction as will cause it; a well marked instance has however been described by Mr. France,<sup>(b)</sup> the accident arising from the woman, when stooping, striking her eye violently against the corner of a clothes-horse.

A good example of subconjunctival dislocation presented itself to me last year, and a careful drawing was made at the time, from which the annexed figure has been copied.

*Subconjunctival dislocation of the lens.*—James Gambel, aged 17, was brought to my house May 23, 1856. The day previous, whilst "larking" with other lads, he received a severe blow on the right eye from a clod of hard earth; the sight was at once extinguished, and intense pain, continuing for some hours, attended the accident. The eye had been fomented and covered with a bread and water poultice. When I saw him he still complained much, not merely of pain, but of the sensation of something in the eye, aggravated by movement of the lids, and it was with some difficulty that I made a satisfactory examination. The condition of the eye was as follows. There was general ecchymosis; the iris was nearly invisible from the anterior chamber being partially filled with blood; on the inner side just beyond the junction of the sclerotic and cornea, a dark line, evidently a rent in the sclerotic, was visible, and between this and the inner canthus was a yellowish swelling, the size of half a pea;

this was recognised as the lens which lay under the conjunctiva; the conjunctiva had evidently yielded, and the lens had been driven rather beyond its point of exit from the sclerotic.

Observing this, I decided on removing it at once, making the external wound

not corresponding with the rent in the sclerotic and choroid: standing behind the patient, I slit the conjunctiva to the inner side of the lens; then making slight pressure that body started out, together with extravasated blood. The eyelids were then closed and secured with a strip of plaister; cold water dressing ordered to be constantly applied. The patient to remain in bed on low diet.

It is unnecessary to give the particulars of the progress of the case, as they presented nothing remarkable; the patient was brought mildly under the influence of mercury, and strict antiphlogistic treatment enforced. On the fourth day I examined the eye, and ascertained that the iris had been detached at the point corresponding with the wound; the effused blood had been in a great degree absorbed, and the wound in the sclerotic appeared to be healed. At the expiration of a month the eye had partially recovered from the injury, though the traces remained in the disfigured iris and the dark seam which marked the exit of the lens.

For the opportunity of seeing the following interesting case I am indebted to Mr. Heward.

*Partial displacement of the lens.*—A tradesman was attacked by a gang of ruffians on the evening of December 9th, 1855, and garrotted; besides the strangulation, which nearly cost him

his life, a dreadful blow was inflicted on his left eye, which completely destroyed it. For a long time it was the seat of inflammation, but that had subsided when I examined the eye in June 1856. Its condition was then as follows. The globe was greatly diminished in size, soft, and tender to the touch. The sclerotic was of a peculiar dingy yellow hue; the pupil widely dilated, the iris being reduced to a mere strip, and of a leaden colour. The lens, of a dark amber tint and opaque, had been driven upwards and outwards, so that its inner and lower margin were visible at the upper and outer portion of the pupil; behind the lens a coagulum of dark

blood was distinctly visible, the remains doubtless of hæmorrhage into the eye at the time of the injury. Sight completely extinguished.

An extremely rare accident is the partial expulsion of the lens from the eye; I have never met with an instance, but such a case is figured and described by M. Sichel.

*Partial expulsion of the lens from the eye.*—A female, 60 years of age, when sneezing, struck her right eye violently against the corner of a table, and inflicted on it serious injury. Seven days afterwards she consulted M. Sichel. The cornea had been separated from the sclerotic along its upper and inner border, and the condition of the lens is thus described: "The crystalline is opaque, large, of a greyish tint, and covered superficially with small flakes of coagulated blood, which on its inner border extend in folds into the neighbouring region; it is fixed in a direction obliquely from behind forwards between the edges of the gaping wound existing at the junction of the cornea and sclerotic, so that the two inferior external thirds are seen in the anterior chamber, whilst the upper third appears without, covered only by the conjunctiva."

There was a good deal of inflammation; but this being somewhat subdued by the 17th of May, M. Sichel proceeded to remove the lens. With a cataract knife he made an incision, which gave exit to the soft portion of the crystalline. This body itself, its surface marked with coagulated blood, followed, with a portion of vitreous humour, when the incision was completed; the nucleus was yellow. As many fragments of the lens and capsule remained adherent to the posterior surface of the cornea, they were removed with forceps. The lips of the wound were then drawn together. Strict antiphlogistic treatment was adopted, and the case did extremely well, a fair amount of vision being restored to the eye.

(To be continued.)

## SERIES OF CASES ILLUSTRATIVE OF DISEASES OF THE ABDOMEN, AND ESPECIALLY OF THE DIAGNOSIS AND TREATMENT OF ABDOMINAL TUMOURS AND INTUMESCENCE.

By CHARLES J. HARE, M.D. Cantab., L.R.C.P.  
Assistant-Physician to University College Hospital, etc.

### MOVEABLE KIDNEYS—THEIR DIAGNOSIS AND TREATMENT.

(Continued from Vol. XXXV. p. 258.)

THE affection or condition of the kidneys to which I am about to refer in the following observations is one which I believe to be not merely of some interest in itself, but also of considerable practical importance. This "moveable condition of the kidneys," though not very common, is yet, I feel convinced, much more so than is generally supposed, and is, at any rate, not so rare, but that instances of it must present themselves occasionally to most Medical men who are engaged in extensive practice. On the other hand, I feel assured, both from the comparatively little notice generally taken of the subject in books, from the few cases recorded in the Medical Journals, and from conversations with many of my Medical friends that the affection is not so generally known as it ought to be.

An acquaintance with this condition of the kidneys will tend in certain cases to throw much light upon, and to explain a series of otherwise obscure symptoms, or may lead us to an accurate diagnosis of the nature of an abdominal tumour in cases where, if the occurrence of this state of the organ were not known, much uncertainty as to its nature might be felt; hence, too, a favourable prognosis might be given when, under other circumstances, one of a very different character would probably be entertained. All Medical men well know the dread which patients almost always feel when by any accident they have detected a tumour in their abdomen. It has occurred to me, in one of the cases of this affection which came under my care, to be able to remove a great amount of anxiety from the patient's mind, by explaining the nature of the tumour she had detected; and Rayer states that in the cases of two Medical men who suffered from this condition of the kidneys, he was enabled to set at rest the fears they entertained, though one of them actually contemplated relinquishing practice, in consequence of mistaking the nature of the disease under which he was suffering.

When the kidneys are of their usual size, and in their normal position, they give rise to but few physical signs. These organs may, however, occupy positions very different from their ordinary ones, and this malposition may be either congenital or acquired, and associated or not with malformation or alteration of size, and occasionally also with a greater or less amount of mobility. Thus it is by no means an exceedingly rare circumstance for the two kidneys to be so united as to form one body, giving rise to the so-called "horse-shoe," or crescentic kidney. (a) In other, but rarer instances, all trace of renal structure is wanting on one side, while the kidney of the opposite side is almost always, under such circumstances, enlarged. Again, one kidney may be in or near its natural position, and the other in some distant part of the abdomen. Thus Andral mentions a case in which one kidney occupied its normal situation, while the other was placed in the hypogastric region near the bladder. Somewhat similar instances have been described in the works of Bellini, Drouin, Lejeune, and several others, and records of such are to be met with scattered in the pages of more modern Transactions and Journals.

In Bonet's case one of the kidneys occupied the usual position of the uterus, being between the rectum and the bladder. In one detailed by Hohl, the left kidney was situated deeply at the inner side of the psoas muscle, and in two confinements retarded the progress of the foetal head. An interesting example is quoted in the last volume of the *Medical Times and Gazette* (1857, ii. 44). A remarkable case is reported by Sandifort (b), where the left kidney was situated on the last lumbar vertebra, and the upper part of the sacrum, in such a position that its upper end was adherent to the lower part of the right kidney; the two kidneys, therefore, almost formed one mass.

In some instances a kidney may be considerably displaced by the enlargement of another organ, as the liver or spleen; and Rokitsansky remarks, that where such is the case the hilus of the organ "is turned upwards, as the upper portion of the kidney is necessarily most depressed." (c) One of the most remarkable examples is that mentioned by Rayer, where the right kidney was forced low down in the abdomen by an enormously enlarged supra-renal capsule. Cases are even on record in which a kidney has formed part of a ventral hernia.

It is obvious that malpositions of the kidneys, such as the foregoing, might cause these organs to be mistaken for other tumours, and it is with the practical view of suggesting the possibility of a condition of this kind, in very obscure cases of abdominal tumours, that I have cited these examples. Many others of a similar nature might be quoted.

Although the conditions of the kidneys to which I have just now alluded, are sometimes associated with a slight degree of mobility, this is not by any means a chief characteristic of the malformations and displacements alluded to, and the organ can scarcely ever in these cases be pushed into, or even very near to, the normal renal region. But in the affection to which the following observations refer, a certain amount of mobility is the characteristic sign, and it is almost

always such that the kidneys can, at least temporarily, be replaced in their normal position; while the organs themselves are not necessarily in any degree affected with any deviation from the natural size, form, or structure.

I shall subsequently give further particulars as to the relative frequency of this affection in the two sexes, etc., but I may mention here that it occurs very much more commonly among females than males, and that mobility of the right kidney is much oftener met with than of the left, while, if the two organs be affected, the right one is usually the more so. The habitual position of a mobile kidney is almost always lower than natural, but it varies notably according to whether the patient be in the recumbent or the upright position, being lower, of course, in the latter: even when the patient lies on the back, (if the abdominal parietes are moderately flaccid and not too fat), the lower ends or perhaps even the greater part of the kidney may be felt below the costal cartilages.

In examining cases of abdominal tumours, it is often more convenient to stand on the side of the patient opposite to that on which the tumour is situated. In the cases under consideration, however, the best plan to adopt is the following:—Suppose the right side is to be examined; the patient being laid on the back, with a slight inclination towards the right side, the head and shoulders being raised, and the legs somewhat elevated, the observer should stand or sit to the right of the couch, but somewhat facing the patient, and should place the fingers of the left hand on the postero-lumbar region, immediately under the last rib, at the same time gently pressing or pushing forwards that part. The ends of the fingers of the right hand should then be placed in front, just below the costal cartilages, and there also a slight pressure should be exerted: the lower end of the kidney will thus probably be felt between the two hands. The patient should next be told to take a deep inspiration, and then to expire slowly; the observer should in the meanwhile keep his hands in the same position as before, but, just at the commencement of expiration, should press the fingers of the right hand rather sharply down towards the renal region, and he will probably detect a much larger portion of the kidney between the hands than previously: it has been detruded downwards by the action of the diaphragm. Sometimes the kidney may thus be retained between the hands, and now and then it may be detruded much lower into the abdomen, but it usually slips away from between the fingers, and is lost for a moment under the liver or in the proper renal region. In other cases, where the mobility is greater, if, at the moment of commencing expiration (after a deep inspiration), the right hand be pressed *edgewise* along the margin of the costal cartilages, and sharply downwards towards the renal region, the kidney will very probably glide or slip downwards, so that the whole of it will be below the hand—below, that is, the level of the position where its inferior border is usually situated.

In other instances, without this manipulation, the kidney is felt as a body so movable that it can be taken up, as it were, through the parietes, and be shifted or pushed to different parts of its own side of the abdomen or even moved to the front of the spine. The degree of mobility, therefore, varies very much in different cases; it may amount to but a slight departure from the usual tolerably fixed condition of these organs, while, on the other hand, I have met with a case in which the right kidney could readily be moved upwards and downwards, over a space of between four and five inches, and to a considerable extent transversely across the right half of the abdomen.

The following sketches show the position of the kidneys in two instances of the affection, during the ordinary condition of the patients when recumbent; and also exhibit the alterations effected on the position of the viscera by deep inspiration and by manipulation, as just described.

The sensation on palpitation communicated by the kidneys to the fingers, is such that the organs can scarcely be mistaken for any other kind of tumour: they present, more or less perfectly, the kidney shape, the lower extremity is rounded, the surface very smooth, the mass itself hard and resisting; although it can be detruded downwards, it also glides with great facility back into the lumbar region. Pressure very generally gives rise to more or less tenderness, and may produce pain even shooting down the thigh or to the lower part of the abdomen; very generally a peculiar faint or sinking sensation is produced by pressure. When the kidney is dis-

(a) A good example of this malformation of the kidney was presented to the Pathological Society by Dr. Bence Jones. (Trans. Path. Soc. Lond., vol. vii. p. 264.) The single kidney weighed 20 ounces.

(c) Rokitsansky (Byd. Soc.), ii. 187.

placed downwards a kind of void is felt by the hand applied to the postero-lumbar region, and in one or two cases Rayer mentions having observed a flattening or depression of that part. Dr. Gueneau de Mussy informed me that in a case under his care this depression was very remarkable, and was especially so when, at his request, the patient supported herself on the hands and knees. I have recently again seen the

patient represented in wood-cut No. 1, and found a greater flattening or hollowing out of the right postero-lumbar region, then of the left; but the difference was very slight. Professor Oppolzer, as quoted in the *Medical Times and Gazette*, (1857, vol. i. p. 576) does not mention this condition.

In the next part of this paper I shall refer to the symptoms produced by this condition of the kidneys, and to the appearances which have been found in some cases where, with this affection, patients have died of other diseases.

(To be continued.)

## NEW INSTRUMENT. THE POLYPTOME.

This instrument has been invented within the last few weeks for Dr. Lever, by Messrs. Bigg and Millikin, of St. Thomas'-street, Borough, and is intended to facilitate the operation of removing broad-based uterine polypi. The instrument, as may be seen from the engraving, consists of a semicircular blade cutting by its concave edge, which plays freely round a circular joint placed at the end of a steel stem or shaft  $5\frac{1}{2}$  inches long, when worked by a trigger and thumb piece or crescent, which pushes a slide and lever acting on the blade, forward and back. When prepared for use, the lever is drawn back, the edge of the blade being then passed over the part which is to be excised; the operator may now make gentle traction by means of the handle, while by pulling the trigger he causes the blade to sweep forward with a cutting movement, for about  $1\frac{1}{4}$  ins. The instrument now becomes a cutting hook, the cutting edge being in the whole length of its concavity. The operation may now be completed with this hook by simple traction, or, if the base be too broad for this to be done, the lever may be withdrawn with the thumb, and the first step of the operation repeated.

This ingenious contrivance gives the operator the advantage of exercising at will, either the cutting motion of a knife, or what is technically termed "incision by traction;" an advantage which will, no doubt, be fully appreciated by those surgeons who are

at all acquainted with the difficulties met within performing these operations.

There is an "hook," very similar in shape to that formed by the cutting-blade and shaft of Messrs. Bigg and Millikin's "Polyptome" when the lever is thrust forward, in the Museum of the Royal College of Surgeons. It is evidently of very ancient date, and is unnamed. It lies close to a box of amputating instruments which were taken from the French in Egypt; but it is simply a solid hook, intended only to cut by traction, like the elegant polyptome of Dr. Simpson.

**MEDICAL PEDESTRIANISM.**—A Medical man, of forty years' practice in Philadelphia, informed us (*Phil. Med. and Surg. Journ.*) that he had walked in that time above 150,000 miles. How many of the present generation of effeminate doctors will ever accomplish this feat? This gentleman, at the ripe age of 69, is now as active as a boy of 16. He commenced walking in his practice on account of an inveterate dyspepsia, and has been able to keep the enemy off only by continuing the practice, and by close attention to diet.

THE LONDON  
PRACTICE OF MEDICINE AND SURGERY.

THE CITY OF LONDON HOSPITAL FOR  
CHEST DISEASES.

TWO CASES OF CHRONIC PNEUMONIA IN YOUNG  
CHILDREN.

(Under the care of Dr. RISDON BENNETT.)

THE two following cases are of much value, on account of their being very carefully observed over very long periods: In chronic disease it is so often the lot of the Hospital Physician to see but a part of his patient's case, and never to know the final result. The form of chronic pneumonia the results of which these cases illustrate is besides, as far as our observation has gone, far from being of frequent occurrence. In the first of the two it will be seen, that although the patient recovered constitutionally, yet some local softening took place. In the second the recovery might be deemed complete.

*Case 1.*—Susan Flint, aged 5½, was admitted on December 18, 1854, with the account that she had had measles and whooping cough together at the age of three years, and had never been well since. She was an emaciated cachectic little child, and suffered much from cough and dyspnoea. On examination a large extent of almost complete dullness was found under the right clavicle, where also the respiration was blowing. There was also a large extent of comparative dullness over the lower lobe of the same side posteriorly. Dr. Bennett prescribed the cod-liver oil in doses of two teaspoonsful three times a day, and after about a month a quinine draught was added. She continued an out-patient. In April of the following year the note states that she was very greatly improved in general health, and that the dullness was much less marked in degree. The same treatment was steadily continued through the next summer and autumn, and the note in December records progressive improvements in all respects. The iodide of potassium in grain doses taken in sarsaparilla was now substituted for the quinine, the oil being still persevered with. The note in the November next following (nearly two years from the beginning of the treatment) states, "She looks very well, and has a good fixed colour in the cheeks, and florid lips; is very active, and plays in the streets from morning to night. Very seldom, and only after violent exercise, does she show any indications of dyspnoea. Her mother considers that never since her birth has she been so well as during the past year." Notwithstanding the so complete restoration of her general health the signs of local disease still existed. Percussion beneath the right clavicle still gave the box-like note of consolidated lung, and the sense of resilience to the finger was wholly wanting. Some vesicular breathing was, however, now to be heard, but in parts there were moist sounds, very like the gurgling of small cavities.

It seemed not unlikely that the condition known as "cirrhosis of the lung" would eventually be assumed by the affected portions.

*Case 2.*—Alfred Kilbey, aged 4, was admitted under Dr. Bennett's care on June 21, 1852. The history given was that eleven months ago he had had the measles, after which the scarlet fever, and as a sequela to the latter, a severe and prolonged attack of general dropsy. The dropsy lasted more or less for six months, and had disappeared only about four months before admission. He was emaciated to an extreme degree, and suffered from a severe and distressing cough. The expectoration was profuse, but had never contained blood. On physical examination, general dullness of the left side was discovered, being most complete posteriorly. In all parts bronchial breathing was heard. The chest was depressed in front, but there was no contraction posteriorly or laterally. Dr. Bennett prescribed the cod-liver oil, and a powder containing a grain of grey powder, to be taken every night, but the boy could not be got to take the oil, and a fortnight later a mixture containing a grain of the iodide of potassium, and half an ounce of the compound decoction of sarsaparilla, was substituted, to be taken three times daily. The medicine was continued, and various mild counter-irritants, as the tincture of iodine, the turpentine liniment, etc., were from time to

time applied to the chest. He improved very greatly in health, and on November 15 it was noted: "He is now very fat, though rather pale and puffy. Appetite good. He sleeps well, plays about actively, and has little or no cough." As in the preceding case, however, the local amendment had by no means kept pace with the improvement in the boy's general health. On this point the note proceeds: "His left chest is still very dull in all parts, especially behind, and bronchial expiration, with an occasional moist rhonchus, is heard everywhere, excepting beneath the clavicle. In the last-named region respiration is more clear. The voice is bronchophonic in all parts, and the vocal fremitus is decidedly better felt on the left than the right side. The heart is not displaced." On July 25 the note says: "There is still comparative dullness over the whole left side of the chest, and the respiration is feeble. No moist sounds. Vocal thrill increased. The chest appears to be contracting."

The iodide and sarsaparilla mixture was continued until June 27, 1853, when, in addition to it, a teaspoonful of cod-liver oil was ordered. The oil was only taken for about three months, when, disagreeing with the stomach, it was again abandoned. The sarsaparilla was subsequently continued until July 27, 1854 (two years altogether), when the boy was discharged "cured." Dr. Bennett's note dictated at this date is: "He is now stout, and has gained a healthy degree of colour. His mother reports that he can run and play as actively as other boys. Fingers not in the least clubbed. Percussion sound almost clear throughout the left side, and breathing everywhere heard, though rather more harsh than on the opposite one. There is also slight mucous crepitation heard occasionally."

Those skilled in the knowledge of the sources of deception which in certain cases exist as to the diagnosis between solidified lung and pleural effusion, especially in children, will be ready to suspect that the above case might have been after all one of empyema rather than of pneumonia. Nor is it improbable but that in the commencement of the affection a certain amount of fluid might have been present. That the chief dullness was, however, caused by pneumatic condensation, the presence of bronchial breathing and of moist sounds placed beyond doubt. We have therefore an exceedingly interesting and probably very rare example of complete recovery from very extensive and long continued consolidation. The condition probably was that known as "strumous pneumonia" of a very much more chronic type than any form of inflammation of the lungs which occurs in the adult. It should have been stated in the narrative, as bearing upon the etiology of the affection, and its connexion with the attack of scarlet fever, that the urine was examined early in the boy's attendance, and found to be quite free from albumen.

ADDITIONAL FACTS AS TO THE CAUSTIC  
TREATMENT OF CANCER.

WE recorded in the last volume of the *Medical Times and Gazette*, a series of cases, chiefly under the treatment of Mr. Stanley, in St. Bartholomew's, in which the removal of cancerous tumours by diluted applications of the chloride of zinc in solution had been attempted. It will be of interest now, after the lapse of six months, to review the practice; and we shall also take the opportunity for bringing together such other facts relating to the employment of other forms of caustic for this purpose as have recently attracted our attention in the different Hospitals.

The following is a brief resumé of Mr. Stanley's cases:—

*Case 1.*—Mary Poyne, from whose breast a cancerous tumour had been wholly removed, remains quite well up to the present date.

*Case 2.*—Mrs. Forster. In this the cancerous mass was never wholly got away. She has since died of the disease, with symptoms of internal deposits.

*Case 3.*—Is still quite well.

*Case 4.*—A man with a deep ulcer in the groin, the result of glandular disease consequent on soot cancer. The caustic did no good on account of the too deep spread of the disease. He left the Hospital *in statu quo*, and is doubtless since dead.

To these cases we now add the following:—

*Case 5.*—Sophia Lane, aged 47, was admitted under Mr.

Paget's care on May 27. A mass of scirrhus of considerable size, and of stony hardness, occupied the centre of the right mamma, and was stated to have existed for ten years. It had been increasing rapidly for five months. The nipple was retracted, and the skin puckered. The tumour had no adhesions to the deep parts, nor were the axillary glands enlarged. She was in feeble health, and had been much reduced by the pain of the cancer. It having been determined to prefer the escharotic treatment, the skin was destroyed by the application of the Vienna paste, having first been rendered insensible by a freezing mixture. On June 9 the slough separated, and the scirrhus mass was now fairly exposed. Burnett's fluid (nine dilutions) was now applied continuously, after the manner which we have formerly described. The gradual separation of leathery sloughs followed, and on July 19 the process of enucleation appeared to be complete, and the base of the sore was quite healthy. It was now allowed to heal, and has remained sound ever since (October 23.) The solution had caused some pain when applied, and to diminish this morphia had been added to it.

One or two cases are at the present time under this treatment, and Mr. Stanley and Mr. Paget continue to think favourably of it.

#### DR. FELL'S PASTE.

Dr. Fell does not seem to have been able to impress the Profession with any very favourable estimate of the plan by the chloride of zinc and sanguinaria paste. It has, as far as we are aware, been very little tried in the Hospitals. One case was so treated under the care of Mr. Simon, in St. Thomas's, and another under that of Mr. Hutchinson in the Metropolitan Free.

In Mr. Simon's case the patient was a woman, aged 65, apparently in good health. The cancer occupied the outer half of the left breast, and was at least as large as a closed fist. It did not adhere either to the skin or pectoral muscle. The axillary glands were not enlarged. The disease had existed for more than a year, and she had been under observation at the Hospital for several months. At Mr. Simon's request the treatment was carried out by Mr. Sidney Jones, who had attended Dr. Fell's practice, and become familiar with the details of his plan. It was, therefore, carried out in every respect after the directions of its advocate. In the first place, by means of strong nitric acid, a surface of integument the size of the palm of the hand was destroyed so as to expose the tumour, and this done, the chloride of zinc and sanguinaria paste was applied on worsted threads by means of longitudinal incisions. A period of about six weeks was occupied in the separation of the slough. The latter when finally removed was nearly the size of a muffin, and about twice as thick. The wound had already commenced to contract, and it granulated rapidly and healed well. Almost as soon, however, as the wound was fairly cicatrized a small recurrent mass was formed in the inner part of the remaining portion of the gland, and in a little time numerous tubercles formed in the adjacent skin. The woman's health had been much broken down by the treatment, and she left the Hospital in a very feeble condition. A very troublesome symptom from which she suffered was intense aching pains in the limbs without any apparent local cause. Soon after her discharge symptoms of consolidation of the lower lobe of one lung appeared, and she died, evidently of internal cancer, about four months from the commencement of the treatment. No autopsy was permitted. It should be stated that throughout the treatment the sanguinaria had been given internally in grain doses three times a day, according to Dr. Fell's recommendation.

With regard to the pain caused in this case, excepting that of the nitric acid, it was never very severe. Still opiates were required throughout, and the woman's strength evidently gave way from the protracted suffering, although the latter was not at any time of unendurable character.

Mr. Jones informs us that he has tried this plan in two other cases, both under Mr. Simon's care. In one a man had a large ulcerated epithelial cancer on the face. The application gave so much pain that after its sixth employment, although well aware that his disease was otherwise hopeless, the poor fellow refused to submit to it any longer. He is since dead. In the third a woman with cancer of the breast also refused to allow the treatment to be continued on account

of the horrible pain caused. In both these latter opiates were freely used.

The facts of Mr. Hutchinson's case are as follow:

Barbara Rosamond, aged about 40, was admitted on account of a mass of scirrhus the size of a duck's egg, in the outer part of the right breast. The tumour was not attached either to the skin or the muscle. An elliptical portion of integument, which was very thin and lax, was removed, and three days afterwards the application of Dr. Fell's paste was commenced. Incisions were practised and the treatment conducted exactly on the method directed. The application caused very severe pain after the first few times of use. On the 13th day a mass of slough, including apparently the whole of the diseased growth, came away. It was of the shape and about the size of the half of a small orange. The wound now presented a healthy surface, and rapidly contracted. Before, however, cicatrization was complete it became plain that the base of the sore was again cancerous. After waiting a little while it was noticed that the induration was rapidly increasing. The adjacent parts of the scar having been destroyed by nitric acid, the zinc and sanguinaria paste was again used. The result was nearly the same as before, but intentionally not so rapidly produced. In from three weeks to a month the slough came away. The wound now healed perfectly, and the woman left the Hospital. In less than a month, however, from the date of her discharge a new growth commenced in the breast beneath the scar. She was now quite tired of the caustic, and having seen several patients in the same ward recover quickly after removal by the knife, insisted upon the performance of the operation. The caustics had occasioned her much pain. The breast was excised about a month ago, and she is now quite well.

This case was of much interest in reference to current pathological doctrines respecting the antagonism between tubercle and cancer. She had been for years supposed to be the subject of chronic phthisis, and had attended as such at a special Hospital. About a year before the appearance of the cancer all her chest symptoms, to her surprise, vanished, and she recovered a most unwonted degree of health. To use her own expression, "her constitution seemed quite changed." At the time she was admitted on account of the cancer her chest was much flattened, and her breath was short; but she had no symptoms of existing phthisis.

#### THE ACID SULPHATE OF ZINC PASTE.

Amongst the new forms of caustic which the recent discussion respecting them has been the means of bringing into use, one of the most convenient appears to be the sulphate of zinc with sulphuric acid. The powdered salt is moistened with the concentrated acid, and applied in a paste form to the sore. It has been proposed, and successfully employed in one or two cases, by Mr. Henry Thompson. A great recommendation is, that its ingredients are always at hand, and easily manipulated. Its efficiency also appears to be great, and the resulting cicatrix soft and good.

### HOSPITAL NOTES.

#### CONIUM IN INDURATIONS OF THE TONGUE.

Conium in very large doses is a favourite remedy with Mr. Lloyd, of St. Bartholomew's. An interesting case has been recently discharged from his care, in which an indurated lump in the tongue very markedly softened down under its use. The patient was a married woman, aged 47, who had had several miscarriages, but no living children. Her aspect was suggestive of syphilis, but there were no positive facts either in the history or existing symptoms. When we saw her last, she had taken the conium (in doses of five grains, gradually increased to a scruple, three times daily) for several months, and the induration, which had been large, and had occupied the centre of the organ, had all but vanished. It had been suspected at first to be of malignant nature.

#### DIAGNOSIS BETWEEN CANCER AND CONDYLOMATA.

A young married woman is now under Mr. Lloyd's treatment in St. Bartholomew's, whose case well exemplifies the

need for great care in expressing opinions as to the nature of growths which have the slightest resemblance to cancer. She was originally admitted about nine months ago, for some small indurated tubercles on one labium, not at all dissimilar from condylomata, of more than usual hardness. There were three, and they were quite distinct from each other. This fact, together with the patient's age and good state of health, induced many to believe them of syphilitic origin. Mr. Lloyd, however, held a contrary opinion, and determined to excise them. This was done, and on microscopic inspection the elements of epithelial cancer were detected in abundance. The woman left the Hospital well, but she has now returned, with a recurrence of undoubted cancerous ulceration in the same site. The glands in the groin, being enlarged, have been excised.

#### A POINT IN THE PROGNOSIS OF CATARACT CASES.

After operating the other day on a case which exemplified the conjunction, Mr. Critchett took occasion to remark that an unusually tough capsule and a soft lens generally, according to his experience, indicated a diseased globe. There is every reason in the case which elicited the remark, to fear that it will be borne out, and that the patient will not regain good sight.

#### USE OF THE ÉCRASEUR IN OVARIOTOMY—PRECAUTION BEFORE TAPPING OVARIAN CYSTS.

In a case of ovarian tumour at the Samaritan Hospital, last Tuesday, Mr. Spencer Wells proposed to use the *écraseur* for the division of the peduncle, should it prove after exploratory incision that the sac or tumour was non-adherent. The tumour was a very large one, and interfered materially with the respiration and comfort of the patient, an unmarried young woman. Mr. Wells made an exploratory incision between two and three inches long in the linea alba, commencing an inch below the umbilicus, opening the peritoneum carefully upon Mr. Key's broad hernia director. Then instead of finding the sac, as usually happens, some folds of small intestine distended with gas appeared in the wound. On introducing the finger the tumour was felt behind several other folds of intestine. It was moveable, but it would have required so large an incision to reach it, and so much manipulation of the intestine that it was determined to close the wound at once. Up to Thursday afternoon the patient was going on well, not having had a bad symptom. A curious point of diagnosis was brought out in this case. The abdomen was quite dull on percussion at the very spot where the incision was made, and where the distended intestine was interposed between the tumour and the abdominal parietes. This fact was completely established by Dr. Routh, Dr. Graily Hewitt and others, even after the closure of the wound, so that had the cyst been tapped without an exploratory incision previously, it is quite certain the trocar would have gone through a fold of intestine. The *écraseur* seems likely to prove of great use in ovariectomy, as the ligature of the peduncle and the consequent death of the stump are doubtless causes of the peritonitis which so often leads to a fatal result. This case of Mr. Wells's is most likely the first in which the use of this instrument has been proposed, with the exception of a case of Dr. Snow Beck's, some months ago, in which Mr. Wells also proposed the exploratory incision and *écraseur*, but which was afterwards treated by iodine injection.

#### UNUSUAL DISLOCATION OF THE FEMUR.

An opportunity for examining a rare form of dislocation of the femur occurred the other day at the London Hospital. A moderately stout man, aged 50, had been admitted, under Mr. Luke's care, after having fallen into a dry dock. A dislocation of the left femur was easily diagnosed, but the symptoms were peculiar, inasmuch as the limb was lengthened one inch, without either inversion or eversion. Yet the head of the bone could be easily felt, and was thought to be in the ischiatic notch. By manipular movements reduction was easily effected about an hour after the accident. The man subsequently died from the effects of broken ribs. At the autopsy Mr. Forbes, the House-Surgeon, before dissecting the parts, again dislocated the bone. This was done with ease, and it was clear that the original form of dislocation had been reproduced, as the bone could not be made to assume any other position. The head of the bone proved to be displaced

neither into the ischiatic notch nor the thyroid hole, but midway between the two, immediately beneath the lower border of the acetabulum. The gemellus inferior and the quadratus femoris had been torn, the ligamentum teres had been wholly detached, and there was a laceration in the lower part of the capsular ligament. These irregular forms of dislocation of the femur appear, judging from the recent experience of our Metropolitan Hospitals, to be far from infrequent. The fact is, the head of the femur may rest anywhere outside the brim of its acetabulum, and does not by any means necessarily slip into one or other of the positions which had been allotted to it under such circumstances in surgical classifications. It is an important feature in the plan of treatment by manipulation that an accurate diagnosis, as to exact position, is by no means necessary to successful reduction.

#### SYPHILITIC INFLAMMATION OF THE RETINA.

The revelations of the ophthalmoscope bid fair to add a peculiar form of retinitis to the acknowledged *rolé* of symptoms due to constitutional syphilis. A fortnight ago we noticed a very interesting case, in which lymph had been seen deposited on the retina of an infant, the subject of hereditary syphilis. A few days afterwards Mr. Critchett admitted a second case, in which a girl, whose history and appearance led to the belief that she was the subject of the same kind of taint, was losing sight in both eyes, from the punctate effusion of lymph on the retina. Two other cases are attending Mr. Critchett's clinique, in which, in connexion with acquired syphilis, retinitis with effusion has occurred. In one the effusion is in the form of isolated white dots; but in the other the whole visible extent of retina is cloudy and opaque, the optic nerve itself being but dimly seen. It is worthy of note, that in neither of these cases has there been any iritis or affection of the anterior parts of the globe.

#### PUNCTURE OF THE HEAD IN HYDROCEPHALUS.

This operation is resorted to with extreme rarity in London practice. On Tuesday last Mr. Lawrence adopted it in a case of much interest. The patient was an infant, aged nine weeks, the subject of congenital hydrocephalus. Part of the bones of the skull were separate from each other, and their margins could be easily felt. The chief protuberance was backward, the forehead being very slightly enlarged. The symptoms had become urgent, the child being dull, and almost in coma, and its eyes fixed and motionless. A small trocar was used, and about eight ounces of clear serum removed. The operation was borne remarkably well, and was productive of great immediate relief. No irritation whatever appeared to have been caused, nor was there any tendency to syncope. The mother was allowed to take the child home in the evening, and up to the time of its removal all seemed to promise well. We shall advert to the final result at a future time. The fluid removed was albuminous, of sp. gr. 1.009, very alkaline, and effervesced on the addition of acid.

#### THE HOSPITAL PHARMACOPOEIA.

UNDER this title we propose, from time to time, to copy some of the best formulae of our Hospitals, and to bring together certain miscellaneous notes concerning the art of cheap prescribing. Admitting most fully that in nothing more than in prescribing is it easier to be penny wise and pound foolish, and that a niggardly substitution of an inefficient cheap drug for an efficient expensive one, is in the end the worst economy as well as the worst humanity; yet there is without doubt much of very useful knowledge to be had on this matter; and a very important matter it is to Hospitals, Dispensaries, and to Union Surgeons. Nor need we be told that skill is always cheap, and that speed of cure and saving of drugs is to be effected rather by the study of diagnosis than by minute attention to the details of formulae. We grant the truth of the remark in the main, but it is far from the whole truth, and we still contend that much may be done in both directions. In pursuance of this object we purpose to attempt to supply a deficiency in our Hospital Pharmacopoeias, namely, that they do not indicate the intentions of their formulae. Without promising any approach to completeness in our scheme, we intend to indicate in as few words as may be th

end for which the prescription under comment is usually ordered. We have only to add, that we shall feel much obliged by the co-operation of any of our readers, connected either with Provincial or any of our smaller London Institutions, who may forward to us copies of formulæ believed to possess advantages over those in common use.

#### DIAPHORETIC COMPOUND CAMPHOR POWDER.

The prescription for an excellent diaphoretic powder, which we copy from the Pharmacopœia of the York County Hospital, is the following. Take of nitre ʒiij., of Dover's powder ʒvj., and of camphor ʒix.: the camphor, having been carefully powdered in the usual manner, is mixed with the other ingredients. The dose is a scruple, taken at bedtime in gruel. The powder has long been a favourite prescription of Dr. Simpson's, of York.

#### EXPECTORANT PILLS FOR CHRONIC BRONCHITIS.

℞ Extract. cenii, ext. hyoscyami ʒā ʒj., pulv. scillæ, pulv. ipecac. ʒā ʒij. Ft. mass. in pil. divid. gr. v. in sing. This formula includes the best of our expectorants, combined with mild but efficient anodynes, and is exceedingly useful in allaying the bronchial irritability attending many forms of chronic cough.

#### DIURETIC PILLS.

Under the name of the "Hydropic Pill," the following has for long held a place of high estimation in many Pharmacopœias:—℞. Pil. hydr. gr. j., pulv. digital. gr. ʒ, pulv. scillæ et pulv. zingib. aa gr. jss. Ft. pil. It should be taken three times daily, and is of especial service in dropsy from hepatic disease, being also often useful in that of cardiac origin. In renal dropsy it is of course objectionable on account of its mercurial constituent.

#### COLCHICUM PILLS.

A formula consisting of blue pill, the acetic extract of colchicum, and extract of hyoscyamus, in the proportions of a grain of each of the former to two of the latter, is an exceedingly valuable one for ordinary employment in cases of gout, rheumatic gout, and arthritic eczema, iritis, etc. It may be taken twice or three times a day in acute attacks, but in chronic cases is very useful when given only every night. In the Guy's Pharmacopœia Dover's powder is substituted for the hyoscyamus, and is perhaps an improvement. This pill taken night and morning, with a scruple dose of acetate of potash given three times in the day at the same time, is perhaps the best of all treatment for cases of inflamed eczema, an affection which in many cases has a latent gouty origin.

#### ATROPINE DROPS.

The formula for the atropine drops in use at the Royal Ophthalmic Hospital is two grains of the sulphate of atropine to an ounce of distilled water. This solution is mainly employed for dilating the pupil, in order to allow of better examination of the state of the eye, and also prior to needle operations. At this Hospital the pupil is never dilated before the performance of extractions. Dilatation of the pupil to its utmost possible extent is desirable before inspection with the ophthalmoscope. Attention to this hint will prevent disappointment, and the loss of much time to novices with the instrument. In the course of iritis, when it is deemed desirable to employ belladonna, the extract itself rubbed up with warm water, and used as a fomentation, is preferable to atropine. It should be used as warm as can be borne.

#### NOTES AND QUERIES.

℞: that questioneth much shall learn much.—Bacon.

#### No. 225.—EPITHELIAL CANCER.

I should feel deeply indebted to any gentleman who would furnish me with the results of Cases of Epithelial Cancer of the extremities, penis or scrotum, in which amputation has been performed before any affection of the lymphatic glands. My own impression is, that in the majority of these cases the

disease does not recur; but I am anxious to check my own experience by that of others.

30, Devonshire-st. J. ZACHARIAH LAURENCE,  
Portland-pl. F.R.C.S., M.B. Lond.  
London, Dec. 18, 1857.

#### No. 226.—DISEASES INCIDENTAL TO VEGETARIANS.

Will any of your readers inform me what are the diseases most frequent among vegetarians? Dr. Lambe and other M.D.s. favourable to this diet state, that "vegetarians, without exception, experience an easy death, without the slightest pain;" and that "carbuncles and boils are unknown to them!" Do the marine algae form part of their diet, and how are they dressed?

FACTA NON VERBA.

December, 1857.

#### No. 227.—INSURANCE ON SMOKERS.

Has the Tobacco controversy made the Medical officers of Insurance Companies more cautious in accepting the lives of excessive smokers? Do they put the question to all proposing insurance? Is the query proposed in their papers? Or has the tobacco controversy ended only in smoke?

December 28.

NICOTIN.

#### ANSWERS.

#### No. 222.—DEPILATORIES.

An anonymous correspondent informs me, through the medium of your valuable Journal, Dec. 12, that I shall find a highly efficacious formula in the *Pharmaceutical Journal* for September, 1857. I have perused the whole of the *Pharmaceutical Journal* for September; but not having been able to find the formula alluded to, I conclude that your correspondent made a mistake in his quotation. I should feel much obliged to him if in an early number of the *Medical Times and Gazette* he would tell me with greater accuracy where I can find the above formula. By inserting this, you will confer a favour.

CHARLES LEMOINE, M.D.

Camberwell, Dec. 28, 1857.

#### No. 224.—BLACK-DROP.

"Brathwaite of Kendal" is not dead. Mrs. Brathwaite and her daughter are still living, but ceased to make the Black-drop about three years ago. Probably the secret cannot be obtained without the daughter.

Kendal, December 19, 1857.

## Medical Times & Gazette.

SATURDAY, JANUARY 2.

#### THE ABUSES OF MEDICAL CHARITIES.

THE very able letter of Dr. Ogle, which may be found in our last number, directs the attention of the Profession, and of the public also, to a question of great and increasing importance, namely, the abuses which now prevail in the administration of our Medical Charities.

It will at once be admitted that the destitute poor have at all times a claim to public sympathy; and the laws of the

country provide Medical as well as other relief to that class of the community. We could wish, indeed, that such relief were more equitably administered than it is at present: with more fairness to the Medical officers, and therefore with more efficiency towards the sick poor. But leaving for a time the iniquities of Poor-law Medical administration, which we have never ceased to expose and denounce, we refer at present to the growing evils connected with the administration of our Hospitals and other public Medical Charities.

Admitting as we fully do, that the really destitute have a clear title to Medical as well as other relief, there is a very large and increasing class which cannot be included among the destitute poor, and which nevertheless claims and receives Medical relief from our Hospitals and Dispensaries. Persons tolerably well-to-do in the world, artificers earning two or three guineas a week, gentlemen's servants, and small tradesmen, do not hesitate to avail themselves of the services of our Profession, which are gratuitously rendered to all who demand them. By this system, not only is the Medical Practitioner wronged of his fair chance of remuneration, but the recipients of his gratuitous labours are degraded in their own estimation, and robbed of that spirit of independence which ought to characterise every one above the rank of a mere pauper. Among other incidental evils connected with the present state of things, must be mentioned the contempt which must, in some vulgar minds, be generated for Medical science, when it is found to be so freely and lavishly bestowed without fee or reward; for as the popular belief is that a thing is worth what it will fetch in the market, so, as Medical advice and medicines are not charged for, they may often be considered by the ignorant as worth nothing. Another very serious result is the positive injury to our Hospitals and Dispensaries by the lavish manner in which Medical relief is afforded to their applicants. Putting out of the question the labours of the Medical staff, the cost of drugs for the host of patients who besiege the doors of these institutions is so considerable as to constitute a formidable item in the yearly accounts, and in the smaller establishments to cripple their efficiency in a marked degree.

The consequences are, that in some of the large and rich Medical Charitable Institutions the amount of out-door relief is so enormous (we purposely omit all reference to the in-door patients), that the young Medical practitioners in the vicinity of those establishments must be deprived of all chance of obtaining a living; while, on the other hand, the recipients of such relief often attach no value to assistance which is so indiscriminately bestowed. In the smaller Hospitals, again, and the great majority of Dispensaries, the institutions are actually in debt for the very necessities essential to the continuance of their existence, the chief item in most cases being the drug-bill, owing to the large consumption of medicines by the patients.

In most of these institutions the services of the Medical officers are, with some few exceptions, entirely gratuitous, the only conceivable benefit arising from their appointments being the possibility of their leading to an introduction into practice; a prospect which, in the majority of cases, is perfectly visionary.

In all the Dispensaries, not only do the Medical officers dispense relief and medicines at stated hours to those who apply for them, but they also visit the patients at their own houses, if the cases are of such a nature as to prevent them from attending; and these duties often occupy the greater part of the day, to the exclusion of any other pursuit, either of profit or of recreation. But in some of the Dispensaries not only are these duties gratuitously and faithfully performed, but the Medical officers actually attend the Midwifery cases also; and thus are called up night and day, in

extensive districts, without any remuneration whatever. Now whatever may be urged in favour of indiscriminate Medical relief in other cases, there can be no argument for gratuitous attendance upon those of child-birth, except in cases of absolute destitution, unless, indeed, there be any peculiar difficulty or danger, because child-bearing is a natural operation, and should be provided against by the patient like any other ordinary contingency. Gratuitous attendance in this instance merely encourages habits of improvidence, and the money which is thus diverted from the Profession is most probably spent in the public-house.

The remedy for the notorious evils attending the indiscriminate administration of Medical relief is not difficult to be found. It consists in making the patients of Dispensaries and Hospitals contribute, in some measure, to defray the expenses which they incur. There would be no necessity whatever that the contributions of the benevolent should be withheld under such a scheme; for the additional sums thus made available for the expenses of the Institutions would only supply the deficiency which almost universally exists in the different Charities.

The very poor would, of course, be exempted from any payment whatever; but those who are in the receipt of regular wages would be expected to contribute some trifle to defray the current expenses for the drugs which they receive. In cases of midwifery, the patients would lay by some small sum for their hour of necessity, and by paying this to the Dispensary, they would secure for themselves adequate attendance, and at the same time remunerate in some degree the Medical gentlemen who are appointed to attend them.

The objections to the establishment of such a system are not very important, and may readily be disposed of. It may perhaps be said that the interests of the neighbour practitioners might be injured by the adoption of such a plan; but in our opinion more injury is done to that class of our Professional brethren by the continuance of the present system, which, by giving away advice and medicines to all comers, must inevitably diminish most remarkably the profits of young Medical men who are practising in the vicinity of the Hospitals and Dispensaries. Again, it is well known that most practitioners in densely peopled neighbourhoods are compelled to give away advice and medicines to those who are too poor to pay an adequate price for them, besides losing in bad debts many of the sums due to them from the poorer classes of patients. Now the establishment of Provident Dispensaries would obviate the necessity of absolutely giving away medicines except to the very necessitous; while the Medical men of any given locality might combine together for the support of the Institutions, thus obtaining some remuneration for themselves, and at the same time encouraging habits of prudence among the poorer part of the population.

#### POISONING BY PRUSSIC ACID—THE SALE OF POISONS.

A case has just been tried at Glasgow which has ended in the conviction of a man for poisoning a woman with prussic acid. There are many circumstances in this case which recall the facts made so notorious by the trial of the culprit Tawell at Aylesbury in 1845. The mode of administration, the circumstances under which death took place, the flight of the assassin, and the clear and distinct chain of circumstantial evidence by which the crime was proved, are similar in the two cases. Tawell had a plain and obvious motive,—the culprit Thomson, who has just been convicted at Glasgow, had no motive which the Crown could discover, or even suggest; and as a curious instance of the difficulty of penetrating the mind of a criminal we have it in our power to state, on

RELIGIOUS MELANCHOLY.

Printed by Hallman & Whitson

unquestionable authority, that this man confessed his crime soon after he was sentenced, but said that he could not assign any motive. His mind had been excited by the details of Madeline Smith's trial, and he had a morbid desire to witness the effects of prussic acid on a fellow-creature. Nothing beyond this can, we believe, be stated respecting a motive for this crime. What a strange perversity of human feeling! Thus it was that the crime of Palmer was followed by that of Dove.

The details of the Medical evidence in Thomson's case present many features of scientific interest, and of these we shall probably give an analysis in our next Number. No Medical witnesses were called for the defence, and the Profession and public were thus spared the usual conflict on such occasions as to the relative value of chemical tests, and the quantity of poison which ought to be found in a dead body to justify an opinion that it was the cause of death. The Medical evidence for the Crown was, in our opinion, conclusive and satisfactory; and although the crime was committed in secrecy, the guilt of the man has been as clearly established as if it had been perpetrated in the presence of eye-witnesses.

We have at the present time a reason for alluding to this case. Prussic acid is one of the articles the sale of which it is proposed to restrict by an Act of Parliament. Several instances have lately presented themselves, showing the propriety, and indeed absolute necessity, for such a restriction. To the present system of free trade in the sale of this deadly liquid we must ascribe the recent sacrifice of three lives near Croydon; and, from the evidence in the Glasgow case, it appears that the facility of procuring prussic acid has led to the death of one person, and an attempt on the lives of two others. The druggist who sold it on two occasions to the order of the prisoner was severely reprimanded by the learned Lord Justice Clerk, who tried the case. His Lordship observed that the death of the woman ought to be on the mind of the druggist for life. "He got no satisfactory answer to his question as to the person for whom the poison was wanted; he (the seller) was aware that it was not intended to be put to the use alleged (photography), and yet he gave it on application without further inquiry." It was proved that he supplied for the sum of twopence, on two separate occasions, two drachms of this poison, and for this small sum one life has been destroyed and two lives endangered. It may be very well for the advocates of free trade in poisons to argue that the man might have got a dagger, a knife, or have purchased a pistol with gunpowder and bullets, etc., and if prevented from purchasing poison, he could not have been prevented from procuring these instruments of death. But a man cannot unknowingly swallow a knife, or a dagger, or a bullet in a glass of ale; he would be put on his guard by murder attempted in this fashion; he would call for assistance, and resist the attempt, and these circumstances alone would probably operate as a means of prevention. It is surprising that the interests of men should so cloud their judgment that they cannot perceive any difference in the two modes of assassination. Thus we find them contending that a Poisons-restriction Bill would be of no service to the public, unless it had a knife-dagger-gunpowder and bullet-restriction clause. Is it possible that they do not perceive the absurdity of such an argument as this? Legislation cannot prevent the perpetration of murder, but it may add to the difficulty instead of increasing the facility of perpetrating it.

At present the want of a Poisons-restriction Act throws open to such an assassin as the convict Thomson, a secret and stealthy means of carrying out a murderous design,—a means against which no foresight can guard. There can be

no resistance and no call for assistance, the fatal blow is struck without warning at the small cost of twopence to the murderer, and for an infinitesimal amount of profit to the druggist! The instrument of death too is sold for a purpose to which the druggist either knows or ought to know that it was not applicable. Is this right? Is it morally or legally right that society ought to tolerate such a state of things? We think not; and we believe that nothing but a stringent act of Parliament will prevent the occurrence of such cases as this. At present it would appear that those who deal in poisons are not satisfied with the number of murders and suicides perpetrated by the dagger and the bullet, but they are anxious that there should be additional facilities for the commission of these crimes by perpetuating free trade in poisons.

### THE WEEK.

Australia offers us an oil which seems likely to prove a most agreeable and efficient substitute for cod-liver oil. A cetaceous animal, the Dugong (*Halicornes Australis*, or *Halicornes Dugong* of Cuvier), inhabits the rivers and bays of the eastern coast of Australia, and many of the islands of the Indian Archipelago. It feeds on the submarine algæ and fuci of shallow waters. It attains a length of seven or eight feet, and is described as something between a porpoise and a seal. The flesh is highly esteemed as a tender food, not unlike beef, and it yields an oil so bland and sweet, so free from disagreeable flavour or odour, that it may be given in much larger doses than cod-liver oil. Mr. W. Hobbs, a Surgeon practising at Brisbane, Moreton Bay, has used the oil extensively in many chronic diseases. He is spoken of by our correspondent as a most intelligent man, and from his reports we should certainly conclude that the oil possesses all the useful properties of cod-liver oil. The evidence, to say the least, is sufficient to encourage a trial of the oil in this country, and we trust some Australian merchant will procure a supply without delay.

In further illustration of Sepoy cruelty, a correspondent writes as follows:

"The cases I am able to give you at present are only two: for of the many one hears whispered in drawing-rooms, it is of course impossible to ask the details at once. The first was related to me by the daughter of a late Indian general, and is of a lady who returned, I believe, in the Ripon, and herself wrote previously to say that she had lost her nose and ears. The second I also learnt from the family of a general officer. It is of a young widowed lady (living with her mother at Reading) who has lost both her hands and both her feet, and whose child has also lost its feet. Other cases at Blackheath, Torquay, and elsewhere, I have heard of vaguely, but am not able to give you their details now. In two or three weeks, however, I expect to receive other data for your use from friends at Cheltenham and the Church Missionary College. The Church Missionary Society alone, I believe, have received intelligence of many women in Calcutta who have lost not only the nose and lips, but the breasts also, and still live."

We expect to receive more explicit details on this matter by the next Calcutta mail, and shall give from time to time such information as to cases arriving in England by the Southampton steamers as can be done without breach of confidence, or hurting the feelings of sufferers. It is our firm conviction, however, that all such cases should be known, and we trust that our correspondents, under whose care such cases may come, will assist us in making them known under obvious necessary restrictions.

A most preposterous statement has been made by a contemporary who should be better informed. The argument is,

that though the death-rate in London is only twenty-five in a thousand, yet Londoners are far from healthy, because "twenty in every hundred among one class alone are yearly so ill as to require gratuitous Medical treatment at Hospitals and Dispensaries!" What a miserably diseased population must be represented by such a state of things! But what transparent folly to believe in it! The statistics as to the death-rate are undeniably accurate. The returns from many Hospitals and Dispensaries undergo a well-known culinary operation. In some institutions every attendance of a patient is published as a fresh case. In others a fresh card is given every month. In others, again, these and similar expedients are so ingeniously modified that the benevolent and charitable public are as much deceived as the social economist who stands aghast at the astounding misstatements of unsophisticated innocence.

The Birmingham election business has taken a new turn. A number of subscribers have held a demonstration meeting, at which more ignorance of the great question at issue, more carelessness about the honour of Birmingham, and more recklessness about the interests of the poor, were brought forth than ever could have been anticipated to have sprung from the most uncultivated congregation. Will it be believed that at the meeting we name, a resolution was passed recommending subscribers to Queen's Hospital to withdraw their subscriptions unless the Professors' recommendation was ignored. Will it be believed that the Professors of Queen's College were abused as tyrants, because they hold out in favour of their just and most conscientious conduct so strongly, that even their own interests, their own children, their own selves, are sacrificed to an absolute stranger in support of a principle? In all our experience of the Medical world we have never seen an instance of such noble perseverance under trying circumstances as that which has been exhibited by Mr. Sands Cox, Dr. Birt Davies, and the other Professors of this College. Let them hold on, assured that whatever is so true and so honest can never be put down, though all the Jesuits not in Birmingham alone, but in Christendom, were up against them!

Whosoever says the Medical Profession is not overstocked, let him digest the following:—There was a vacancy last month for a Medical Superintendent of the Dundee Infirmary. The salary is £160 a year, and the candidates numbered upwards of forty. The appointment was obtained by Dr. Glen, a gentleman who has been Resident Physician in the Royal Infirmary of Edinburgh, and has acted as Assistant to Dr. Bennett, in his Clinical Course, instructing special classes in physical diagnosis. He is stated to have a peculiar aptitude for "communicating information to others in a clear and interesting manner." Yet he is one of forty candidates for a place of hard work, constant attendance, and £160 a year. No wonder students' benches are not crowded. As another example of the munificent rewards our leading Physicians and Surgeons may aspire to, we may add that the incredible sum of £30 a year each has been voted to the visiting Physician and Surgeon of this Infirmary by a resolution of the Governors—*Mr. Rough dissenting*. Feeling, doubtless, that the eyes of all Europe were on him, he protested against such mad extravagance.

The deaths of two of our Scotch Medical brethren, who have fallen victims in the fearless discharge of the humane duties of our Profession, claim more than a passing remark. Mr. Gordon and Mr. Henderson, Surgeons of Broughty Ferry, a watering-place about four miles from Dundee, two out of the three

Medical men practising there, died of typhus, one on the 12th and the other on the 13th ultimo. Both took the disease when attending the same poor family in a small dwelling. A Dundee paper says:—"Dr. Gordon had a very high character, both personally and professionally; a man of eminent talent, combining skill with decision, of urbane and engaging manners, of thorough integrity, of unostentatious benevolence, and devoted to his profession with an ardour seldom surpassed, he possessed the respect and confidence of all. Dr. Henderson also had won for himself an enviable reputation; and the fact of his leaving a widow and thirteen children renders his unexpected removal a cause of deepest regret." Typhus was not epidemic at Broughty Ferry. It was introduced to the house by a lodger from Dundee, and appears to have spread in every case by direct contact. As a curious illustration of Medical manners in Scotland, we copy the two following advertisements from the same paper, the date of one being just three days after the death of Mr. Henderson:—

"Dr. W. B. Wingett begs to announce to his Professional brethren and to the public, that he has commenced practice in Broughty Ferry."

"Dr. James H. Park, Surgeon, begs to intimate to the inhabitants of Broughty Ferry and neighbourhood that he has commenced the practice of his Profession.—Miss Nichol's, Fort-street (near the Bank). Dec. 16, 1857."

The Association of General Medical Practitioners of Ireland have addressed Mr. Cowper in support of the general principles of Lord Elcho's Medical Reform Bill, but objecting to the manner in which the principles are carried out. They object—1st. To the preponderance of Government nominees in the Council. 2nd. To the imperfect provision for the preliminary education of students, advocating the expediency of demanding a University degree of "Associate in Arts." 3rd. To the constitution of the Examining Board. And 4th, To the want of any due provision to secure superior attainments by the reservation of public appointments to those who obtain further qualifications than the general license. On a future occasion we shall discuss these important matters fully.

A poisoning case at the Thames Police Court the other day affords another example of the culpable recklessness of the poison dealers. Oxalic acid was sold to a boy nine years of age by another boy of the same age. Mr. Hutchins, the "chemist," and master of the boy, said that he did not allow him to *prescribe for patients!* That it was very wrong of him to sell poison, but he did it "early in the morning before I came down stairs." The magistrate mildly suggests that the boy is too young to be in a poison shop, and hopes nothing of the kind will occur again; and so the Baby Dispenser and his master return to distribute their pennyworths of oxalic acid, laudanum, arsenic, and such like necessities for domestic consumption to the free and enlightened inhabitants of Stepney.

## REVIEWS.

*The Phenomena of Spinal Irritation and other Functional Diseases of the Nervous System explained, and a Rational Plan of Treatment deduced.* By THOMAS INMAN, M.D., Lecturer on the Practice of Medicine at the Liverpool Royal Infirmary School of Medicine. Pp. 201. London: 1857.

Dr. Inman has already expressed some of the opinions advanced in the present volume, by reading a paper on "Certain painful muscular affections, simulating inflammatory, neuralgic, or organic diseases;" and to this paper and the views which it contains we have already drawn attention in our columns. In his present work Dr. Inman amplifies the sub-

ject matter of his original paper, and illustrates his arguments by reference to the history of cases which have subsequently fallen under his observation. He divides his Treatise into two parts, the first being devoted to "Certain painful Muscular Affections," and the second to "Spinal Disorders and other Functional Diseases of the Nervous System." The prevailing idea in Dr. Inman's mind on the subject of the painful affections in question is, that they are due to some morbid condition of the muscles rather than of the nerves, and that the so-called spinal disorders originate most commonly in a feeble and painful affection of the muscles of the back. He records numerous cases in which these affections, having been mistaken for symptoms of inflammation, were treated by depletory measures, and rendered worse in consequence, and in which a due amount of rest to the overstrained muscles, with good diet, effected a speedy cure. Passing from the painful affections of muscles in general to those of the spine in particular, Dr. Inman considers that most of the cases of spinal irritation are really owing to causes originating in the muscles, and that they ought to be treated generally by sustaining the health, giving repose to the affected muscles, and assisting their action, when necessary, by well-contrived artificial supports. Dr. Inman, like Dr. Walshe, does not condemn the use of stays as an article of female dress, but considers them as rather beneficial in aiding the action of the muscles in preserving the equilibrium of the spinal column. The reference of such cases to the general phenomena of hysteria is condemned by Dr. Inman as unphilosophical, and the necessary connexion between hysteria and disorders of the uterus is also called in question. Dr. Inman's views of the nature of spinal irritation are summed up in the following recapitulation:—"We believe that the vast majority of the symptoms considered as the result of spinal irritation arise from over-exertion of one or more portions of the muscular system in debilitated subjects. That the spinal tenderness has a similar origin, and that the other symptoms considered as resulting from spinal tenderness, are concomitants only, and referable to a common cause."

Dr. Inman, in his present line of investigation, has opened up much new ground, and his remarks and reasonings demand the candid attention of the Profession.

*A Treatise on Rheumatic Gout, or Chronic Rheumatic Arthritis of all the Joints.* By ROBERT ADAMS, M.D. etc., Surgeon to the Richmond Hospital, Dublin. Illustrated by Woodcuts and an Atlas of Plates. London: 1857. 8vo. pp. 362.

**RHEUMATIC Gout!** Dr. Garrod says there is no such thing. Gout is gout, and rheumatism is rheumatism. There is no hybrid offspring of rheumatism and gout. Dr. Fuller says there is; but he does not profess to define the precise pathological condition in the cases which he details as rheumatic gout. Mr. Spencer Wells describes a number of different cases met with in practice, in which different forms of rheumatism and gout may complicate each other, and are named without much impropriety rheumatic gout. Dr. Adams implies by this term, chronic rheumatic arthritis; and he gives, in the work before us, the results of the observation and study of a quarter of a century, the substance of numerous clinical lectures, and the principal part of various communications which have been already published.

The work is divided into two parts. In the first part the disease—chronic rheumatic arthritis—is considered generally in five chapters: first, the history; secondly, the causes and symptoms; thirdly, the diagnosis and prognosis; fourthly, the anatomical characters; and fifthly, the treatment. In the second part it is considered specially in each joint, nine chapters being devoted to the disease in the hip, shoulder, elbow, knee, wrist and hand, ankle and foot, temporo-maxillary, sterno-clavicular, and acromio-clavicular articulations, and in the spine. A series of cases, and a very complete index, conclude the work.

This disease as observed among the labouring poor of Ireland differs from the condition observed among the wealthier classes in London, so well described by Sir B. Brodie in his observations "On chronic disease of the joints connected with gout and rheumatic gout." Dr. Adams has never met with layers of lithate of soda on the articular surfaces in any case, and he looks upon complete bony ankylosis as its result as extremely rare; the stiffness and immobility of the joints

arising from alterations in the form of the articular surfaces, not from the union. The chapter on the anatomical characters of the disease as observed in Dublin is by far the best and most accurate account which has hitherto appeared. It and the chapters on the disease in each joint, must be referred to by every surgeon who wishes to master the pathology of diseases of the joints. The following remarks on treatment are most judicious.

"There is one important question which the Medical attendant is frequently called upon to decide—namely, whether the patient should yield to his disorder, and condemn himself, as it were, to immobility for life; or whether he should contend against it, and persevere in walking, even though it proved painful and fatiguing. To this I would reply that, in the commencement of the disease, rest, cupping, the frequent use of leeches, confinement to a warm atmosphere, warm baths, and mercurials, combined with opium, seem to be the most rational means to resort to, with the expectation of arresting the progress of the affection in its early stages; but on the contrary, if chronic rheumatic arthritis has gone on to the destruction of articular surfaces, and the movement of the joint is followed rather by a stiffness of the limb than actual pain, in this case some walking exercise daily may not only be permitted, but recommended to the patient; his general health will be thereby improved, and the articular surfaces will be found to move more freely on each other, owing, most probably, to the exhumation of them, which we know to be induced by motion.

"If, however, upon the one hand, it be true that in the early stage of the disease exercise is likely to aggravate the symptoms, still, upon the other, it is important to have present to our minds the evils that result from the system of the articulations being kept for a great length of time in a state of perfect quietude; for my experience accords with that of Teissier and Bonnet, that prolonged and absolute repose of the joints, particularly in old persons, is calculated to determine serious alterations in the articular structures, such as effusion of a sero-sanguineous fluid into the synovial sacs, the formation of false membranes, erosion and thinning of the cartilages, etc."

Our only regret on closing the book is that the author has not enlarged more on treatment. The cases are very obstinate and troublesome, but much may be done to prevent, to check, and to alleviate by a variety of means that we should have been glad to have seen reviewed by so competent and practical a teacher as Dr. Adams. With the expression of this regret we have only to add the most unqualified approbation of the work. Its value is increased by admirable wood-cuts and lithographs; and it must be regarded not only as most creditable to the author, maintaining and enhancing his high reputation and that of the Dublin school; but as a real acquisition to the medical literature of the age.

*Handbook of the Science and Practice of Medicine.* By WILLIAM AITKEN, M.D. London: 1857. Pp. 786.

It would be a difficult task to attempt any analytical criticism of Dr. Aitken's Handbook, and the best general review of it is to say, that it is just what it professes to be, a Handbook of Medical Science and Practice. Whoever has it on his library shelf may rest assured that he will find in it an epitome of any Medical subject on which he may require the newest, and at the same time the best information.

In accordance with the general plan of works on practical medicine, the greater part of the book is made up of matters relating to the diagnosis and treatment of disease. In treating of the classification of diseases, the author adopts that of the Registrar-General; and inasmuch as this classification promises to become somewhat universal, and may not be thoroughly known to our readers, we may as well place it on our pages. The plan is from Dr. Farr, and will be found on the 3rd page of Dr. Aitken's text:—

**CLASS I. Zymotic Diseases. Zymotici.**

Order 1. Miasmatic diseases. Miasmatici.

" 2. Enthetic (implanted) diseases. Enthetici.

" 3. Dietic diseases. Dietici.

" 4. Parasitic diseases. Parasitici.

**CLASS II. Constitutional Diseases. Cathetici.** Sporadic diseases, affecting several organs, in which new morbid products are often deposited. Sometimes hereditary.

- Order 1. Diathetic diseases. Diathetici.  
 " 2. Tubercular diseases. Phthisici.
- CLASS III. Local Diseases. Monorganicici.  
 Order 1. Brain diseases. Cephalici.  
 " 2. Heart diseases. Cardiaci.  
 " 3. Lung diseases. Pneumonicici.  
 " 4. Bowel diseases. Enterici.  
 " 5. Kidney diseases. Nephritici.  
 " 6. Genetic diseases. Aidoici.  
 " 7. Bone and muscle diseases. Myostici.  
 " 8. Skin diseases. Chrotici.
- CLASS IV. Developmental Diseases. Metamorphici.  
 Order 1. Developmental diseases of children. Paidici.  
 " 2. " " women. Gyniaci.  
 " 3. " " old people. Geratici.  
 " 4. Diseases of nutrition. Atrophici.

Such is the general arrangement under this new nosology. Then follows the placing of special diseases under these several heads. Dr. Aitken sums up:—"The preceding classification of diseases into four groups is not given as a perfect system, but as a convenient grouping of diseases. By its use the student will be able to preserve uniformity in the recording of his cases; it furnishes him with a table of reference to aid him in naming diseases, and a system to guide him in acquiring a knowledge of his profession."—p. 8.

Under this arrangement Dr. Aitken teaches philosophical medicine in its broadest acceptance. There is, for instance, an admirable introduction on the science of medicine, and a final chapter on the geographical distribution of disease, each of which parts should be read by every student, young and old.

Dr. Aitken's style is excellent. He does not attempt the soft and flowing rhythm of Dr. Watson, for his book is rather encyclopædial than academic; but it is no dishonour to the last named distinguished physician and scholar to say, that this "Hand-book" in its deeply read and learned way, is an admirable companion to the classic "Lectures;" and that the practitioner who cannot afford the dearer volumes can find no better substitute for them than Dr. Aitken's Handbook.

*On Consumption; its Nature, Symptoms, and Treatment.* An Essay to which was awarded the Fothergillian Gold Medal of the Medical Society of London. By RICHARD PATTES Cotton, M.D., Physician to the Hospital for Consumption and Diseases of the Chest, Brompton. Second edition; pp. 302. London: 1858.

Dr. Cotton's essay on Consumption is now pretty well known to the Profession, and on the appearance of the first edition we expressed a very favourable opinion upon its merits. In the present edition Dr. Cotton has made use of the additional information and experience which he has acquired in the extensive field of research placed before him at the Brompton Hospital, to render his work as complete as possible. We must therefore again express our approbation of Dr. Cotton's volume.

## PROGRESS OF MEDICAL SCIENCE.

### Selections from Foreign Journals.

#### ON THE EMPLOYMENT OF COMPRESSED SPONGE.

By Dr. ROBERTS.

AT p. 459 of our last volume we gave an account of the great advantage Drs. Foster and Johnson of New York had derived from the employment of compressed sponge for the prevention and treatment of abscess of the breast. In the last number of the *New York Journal*, Dr. Roberts in a letter to Dr. Batchelder furnishes the results of his employment of it under other circumstances. He speaks highly of its utility in dispersing chronic mammary tumours. When employed as tents, formed by first dipping it in weak solution of gum water, and then winding thread tightly around it to obtain the suitable size and form, it proves a most useful application for deep sinuses. "I should be very loth to incise a sinus, until I had tried the effect of a compressed sponge tent introduced to its bottom. By its equal expansion in every direction, stimulating by its

pressure the bottom of the sinus, and laterally destroying the pus-secreting false membrane with which it is lined, and inducing in its walls a new and healthy action, the sinus speedily diminishes in depth, and progresses rapidly towards granulation and cicatrization." Great benefit has also been derived from the application of flat discs of sponge, compressed in the copying machine, to foul and fungous ulcers, the fungoid granulation being repressed, and a healthy sore established. Several unpromising and ill-conditioned ulcers have been healed by this means alone. Another circumstance under which Dr. Roberts has found the sponge useful, is ecchymosis from blows, as in the case of black eye, the discs being renewed night and morning. Again:—"I have several times satisfactorily and easily dilated with sponge the meatus auditorius externus when threatened with contraction after abscess; have succeeded in removing suppurative inflammation of its walls, and obtained an easy access for injections, and an opportunity of observing the tympanum, and thereby cauterizing an ulcerated spot, and once succeeding in the removal of a small polypus, attended with pain, deafness, and profuse discharge." Dr. Roberts has also employed the sponge with success as a tampon in threatened and existing uterine hæmorrhage, and in cases of warty excrescences and intractable ulceration. He recommends the tents as substitutes for the bougie in dilating the os uteri in dysmenorrhœa, the tents being usually passed much more easily, and effecting the dilatation far more rapidly. "Dilatation of the cavity and mouth of the womb also furnishes facilities for cauterising the lining membrane in cases of long-standing leucorrhœa, which often relieves otherwise incurable cases. A piece of fine sponge, between two and three inches long, and as thick as the forefinger, dipped in a thin solution of gum arabic, dried and compressed, by being wound round with fine twine, may be fashioned into a conical form, not much exceeding the size of the ordinary bougie, and passed usually with ease, in the grasp of a long bullet-forceps, into the os, and up into the cavity of the womb." He recommends Dr. Batchelder's plan of attaching a string to his tent, which is as follows:—"Pass a long needle, armed with a strong thread, into the base and through the whole length of the tent, and out at its point; then reverse it, entering at the point, and passing it out at the base. This leaves two threads running the whole length of the tent, doubling at its apex, and passing out at its base, where the two pendent threads may be twisted together, and form a strong cord by which the instrument may be withdrawn. Dr. Batchelder seldom allows the tent to remain in longer than eighteen or twenty hours. On no account should a sponge be passed up without a ligature attached, for it has happened to Dr. Roberts on two or three occasions to have the tent caught out of the grasp of the forceps by a species of spasmodic action, and retained in the uterus beyond the possibility of immediate reach—pain, fever, discharge, and anxiety being the consequences, until the body, in the course of some days, is discharged. "The great extent to which the os and cavity of the uterus can be easily dilated in the course of two or three applications of the sponge, will much gratify those who have not yet employed it in this way." Dr. Roberts believes that these tents constitute the simplest, surest, and speediest mode of inducing premature labour; and he cannot see, if the introduction be repeated sufficiently often, how dilatation of the os, followed by acute uterine contractions, can fail to be induced. Moreover, he is a strong advocate for judicious interference in the early stages of labour, with rigid, undilated, and undilatable os uteri and inefficient pains, a sponge tent being introduced, whether the membranes are or are not ruptured, and maintained there by a tampon in the vagina until dilatation is secured.—*New York Journal*, Nov. pp. 413–418.

#### REDUCIBLE HERNIA STRANGULATED BY TWISTING IN THE SAC.

By Dr. CABOT.

Dr. Cabot was called to see an elderly man who had had a reducible hernia, for which he had worn a truss. About 3 a.m., on getting out of bed, the hernia came down, but he fell asleep without reducing it. On again awaking, he found the tumour very large, and that he was unable to put it back. There was pain in the abdomen. Dr. Cabot saw him at half-past 1 p.m., and found him almost pulseless, and with oppressed breathing. The tumour, which was about the size of the head of a fetus at full term, was blue, cold, and oede-

matous, and there was an absence of gurgling. Above the tumour was a band quite tense. Dr. Cabot proceeded to operate, but found, after removing the tumour from all apparent constrictions, that he could not reduce it. On careful examination, he observed what appeared to be a portion of intestine stretched across, and apparently adherent to the lower part of the sac; and having slit up the whole sac from top to bottom, he found that the whole mass, consisting of a large amount of intestine, was twisted entirely round upon itself, the mesentery forming the band spoken of above, and producing complete strangulation, the portion below being of a deep moroon colour, almost black. The patient died before next morning.—*Boston Journal*, vol. lvii. p. 136.

## EXCERPTA MINORA.

**Arresting Hæmorrhage after resection of the Tonsils.**—In the case of a lad, whose tonsils M. Nélaton removed, with the loss of very little blood, profuse hæmorrhage occurred more than forty hours afterwards. On examining him some time afterwards, the hæmorrhage had ceased; but a small clot adhered to one of the tonsils, on the removal of which the bleeding would doubtless recur. M. Nélaton cautioned the lad against making the alternating movements of expiration and deglutition, which are almost intuitive after this operation, and which are the means of detaching coagula. The caution was well observed, and the bleeding did not return. These consecutive hæmorrhages are so rare, that M. Nélaton has only known of three other examples. If the hæmorrhage had returned in this case, he would have applied the perchloride of iron.—*Gaz. des Hôp.* 1867, No. 143.

**Chloroform in Poisoning by Strychnia.**—A lad, aged 15, swallowed by mistake a powder containing about two grains of strychnia. Dr. Jewett saw him thirty or forty minutes afterwards, and found him with a livid countenance, protruding and injected eyes, a full, strong, and irregular pulse, and his skin bathed in perspiration. Violent tetanic spasms, like the effect of shocks from an electrical battery, occurred in rapid succession. If they relaxed for a moment, the slightest touch of the surface, or presenting anything to the mouth brought them on again with redoubled violence. Chloroform, inhaled with difficulty at first, subdued the spasms in ten minutes, these returning whenever it was suspended. Partial anæsthesia was kept up for about four and a half hours, when it was finally discontinued. The recovery of the boy was rapid.—*Boston Journal*, vol. lvi. p. 491.

**Hereditary Hæmorrhagic Diathesis.**—Dr. Gould communicates a tabular view of the history of a family liable to hæmorrhagic diathesis. From this it results that all the male descendants of a family of "bleeders" for two generations, and many in a third—11 in number—had this constitutional peculiarity. Nearly all were more or less subject to rheumatism. None of the females of the family (although these were more numerous), suffered from hæmorrhages.—*Boston Journal*, vol. lvi. p. 509.

**Vomiting in Pregnancy.**—Dr. C. T. Quintard succeeded in checking obstinate vomiting in a pregnant woman by cauterizing the fauces freely, with a fifteen-grain solution of the nitrate of silver.—*Boston Journal*, vol. lvii. p. 28.

**Left Kidney situated in the Pelvis.**—Examining the body of a man who had died of phthisis, æt. 35, Dr. Isaacs found the left kidney located in the pelvis, its upper end being in contact with the bifurcation of the aorta, and its lower touching the posterior surface of the bladder, and lying on the fifth lumbar vertebra, and first, second, and third pieces of the sacrum. Its right edge was in contact with the rectum, and the left with the iliac portion of the brim of the pelvis. There were three renal arteries, one coming from the aorta, and two others from the right common iliac. The kidney was of the ordinary size, but the supra-renal capsule was twice its natural size, and of the shape of a fig-leaf, and it occupied its normal position in the lumbar region.—*New York Journ.* Nov. p. 340.

**ELECTION AT THE ACADEMIE DES SCIENCES.**—The vacancy in the chemical section made by the death of Baron Thénard, has just been filled by the election of M. Fremy, forty-five out of fifty-nine members voting for him. The other candidates were MM. Berthelot, Wurtz, and Saint-Claire Deville.

## GENERAL CORRESPONDENCE.

## POST-PARTUM HÆMORRHAGE.

[To the Editor of the Medical Times and Gazette.]

SIR,—In your last Number there appears a case of hæmorrhage after the expulsion of the placenta, by Dr. J. R. Pretty, to which are appended some remarks contrasting his mode of treating post-partum flooding with that adopted by me in a case that I published in your Journal for October 6, 1855, and vaunting the superiority of his own method.

Dr. Pretty has, I presume, misunderstood, as he has certainly, by his comparison, misstated my case altogether; the only similarity between them being, that in both there was dangerous flooding. His was an ordinary instance of hæmorrhage after delivery, dependent on uterine inertia; mine was the last I have published of a series of fifteen rather uncommon cases, in which, although the uterus acted vigorously, and with great suffering after the expulsion of the placenta, still alarming hæmorrhage occurred. The cause of distress in all these cases was the retention of a coagulum within the uterus, which was rendered tough and firm by the pressure of the contracting fibres, and which adhered so tenaciously to the inner membrane that the uterus was not able to dislodge and expel it. All these cases were instantaneously relieved by the introduction of the hand and the removal of the extravasated mass, the violent pain as well as the sanguineous draining ceasing simultaneously. For the purpose of stimulating the uterus to contract, Dr. Pretty prefers pressure externally applied to the introduction of the hand within the cavity. I opine Dr. Pretty is by no means singular in this preference, provided only the pressure so employed were sufficient to effect the end proposed. Dr. Pretty quotes Drs. Murphy and Lee as his authorities on this head, the latter of whom says, "I am now convinced that the practice so often employed of passing the hand into the uterus, and pressing its inner surface with the closed fist round and round, to excite it to contract, or to compress the bleeding vessels like a tourniquet, is not only ineffectual for the purpose in the worst cases of this kind of flooding, but that it is attended with mischievous consequences after the flooding has been suppressed." I am as much opposed to any proceedings likely to inflict injury on the uterus as Dr. Lee or any other person can be; and in the cases I have detailed it would be impossible to move the closed fist round and round in the cavity by reason of the strength of the uterine contraction.

Dr. Pretty goes on to say, "Dr. Ramsbotham remarks, 'Nor is it probable that the hand will require to be introduced a second time,' and yet in the very case reported by him this became necessary." This is another erroneous statement of Dr. Pretty. The hand was not required to be introduced a second time for the purpose of staying the *after-hæmorrhage*; the hand was introduced once to remove the placenta, which was adherent, and again, more than four hours after that, to clear the cavity of the extravasated blood that had accumulated within it. My observation had an unmistakable reference to the necessity of a second introduction of the hand to empty the uterus of a fresh accumulation of blood; and, as a proof of the correctness of what I have advanced, in not one of the fifteen cases which I have detailed was that requisite.

Although I am a strong advocate for the application of external pressure upon the uterus in all cases of hæmorrhage after the birth of the placenta, as may be learned by reference to the subject in my work on "Obstetric Medicine," I have never yet seen any kind of compress equal to the grasping pressure of the attendant's hand. When the uterus has contracted pretty firmly, and the hæmorrhage has ceased, or become very much moderated, then a belt such as Dr. Pretty recommends is often of service in preventing fresh relaxation, and consequent return of the bleeding; but while hæmorrhage is going on to any extent, I would rely on no kind of pressure but that which the hand affords.

Dr. Pretty has also misunderstood and misrepresented what I have said regarding the Ergot. He has quoted a few words without the context, and thus made them to bear a signification which does not belong to them. After noticing the depressing influence of the drug, he says, "I disagree entirely with Dr. Ramsbotham that the action of the ergot is specific and that the uterus is not affected through any distur-

first set up in the arterial system." The whole sentence in my book runs thus. After speaking of ordinary stimulants given to excite increased uterine action, I say, "Various specific medicines have been recommended at different times to increase the parturient throes, and facilitate the child's birth; but I believe the whole of these substances, one only excepted, act upon the womb through the excitement produced in the nervous system. They first stimulate the nervous, then the arterial, and through the medium of those systems the uterus. Almost the only medicine now used as an uterine excitant is the ergot; and I have no hesitation in declaring my opinion that its action is specific, and that the uterus is not affected by any disturbance first set up in the arterial system." As the word "disturbance" follows so closely upon "excitement" it is evident that it refers to a state of increased action and not of depression; and it is equally clear, therefore, that Dr. Pretty has completely perverted my meaning. In another part of the same publication I say, "Dr. Hardy states that out of 48 cases which he made the subject of observation, in 19 of these the frequency of the mother's pulse was lessened; and that this effect continued several days.... Although I have known the maternal pulse depressed by the drug, I never knew that state continue for any length of time." So that I was not ignorant of the depressing influence sometimes exerted by that medicine on the heart's action.

In conclusion, I cannot help remarking, that when any one constitutes himself a critic and censor over the practice and opinions of another, the least thing he can do is duly to inform himself of the opinions entertained and the practice followed, and to report those opinions and that practice correctly.

I am, &c.

FRANCIS H. RAMSBOTHAM.

7, Portman-square, Dec. 22, 1857.

P.S.—In the second portion of his paper, Dr. Pretty has entered into the disputed question of the value of large doses of opium in floodings after delivery; and because in his case the uterus, for the first time, was found "unusually well contracted" more than five hours and a half after the removal of the placenta, and at least five hours after the exhibition of a drachm of laudanum with sal volatile, he believes "without it the patient's syncope would have been mortal." He says, "Its action as a stimulant was most decided, and for the time efficient," although she had swallowed "a full glass of brandy" just before she took the laudanum and sal volatile; although "gin-and-water had been continually given in teaspoonfuls" for about an hour and a quarter after the laudanum was administered; although at the end of that time a glass and a half of gin was given; and although in about half an hour subsequently an egg in a glass of gin, and soon after two eggs in a glass and a half of gin. I am at a loss to find out how the stimulant effect of the laudanum could be distinguished from the stimulant effect of the glass of brandy and the four glasses of gin that had been administered.

Notwithstanding Dr. Pretty's opinion to the contrary, I should think the opium did tend to paralyse the uterus in this instance, and that it added to the danger of the case, by preventing the necessary contractions taking place, so long as its influence continued to operate. As I cannot concede the position that "the contractions of the uterus are independent of all connexion with the nervous system," so I believe the effect of opium in full doses is to diminish its contractile powers; and consequently that in the cases under consideration it is only admissible for the purpose of lulling any undue excitability that may remain in the system after the uterus has become permanently contracted, and all danger of fresh hæmorrhage is for the present averted.

### ACTION OF THE HEART.

[To the Editor of the Medical Times and Gazette.]

In the *Medical Times and Gazette*, Nov. 21st, Dr. Pavy reports a case of Fissure of the Sternum, which, I think, ought to be an excellent test or proof of the truth of the systolic or diastolic theory of the heart's impulse. In examining the action and sounds of the heart the most minute accuracy of observation is requisite; and I am gratified to find, that Dr. Pavy concludes his statement with the words, "that the impulse of the heart occurs slightly before the rising of the swelling formed by the aorta."

The contraction of the apex portion of the heart dilates the base; the base then contracts and dilates the commencement of the aorta, causing the rising of the swelling at 'b'; I, therefore, positively and unhesitatingly assert, though I have not seen the man, that the second sound occurs after the impulse at 'a,' and precedes the impulse at 'b,' or, in other words, the impulse at 'b' occurs just at the termination, and not at the commencement of the second sound; consequently the second sound must be produced by the systole or contraction of the heart.

The walls of a living heart, at least of the apex portion, fully dilated, are exceedingly thin, scarcely thicker than a piece of pasteboard or thick brown paper; something of the sort may be seen occasionally in the dissecting room, when a heart has been neglected and left to grow mouldy and rotten. If physiologists wish to see the real action of the living heart, and not the mere spasms and contortions of a dead one, they must open the chest of a living animal, and to avoid unnecessary cruelty, they should use a little chloroform, as in surgical operations, but as little as possible, or else give the animal a gentle rap on the skull, just sufficient to produce insensibility, as I did successfully in my first experiment on a rabbit.

In conclusion, I may remark, that the impulse of the heart is synchronous with the pulse of the carotid; but Dr. Pavy, to my great gratification, kindly observes, "that the impulse of the heart occurs slightly before the rising of the swelling formed by the aorta."

### TREATMENT OF UTERINE HÆMORRHAGE.

[To the Editor of the Medical Times and Gazette.]

SIR,—I frequently read in Medical periodicals fatal, or nearly fatal cases of hæmorrhage after delivery. The treatment of many of these cases appears extraordinary. There is one such related in your last week's *Gazette*, by Dr. Pretty.

In the *Medical Times and Gazette* of April 14th, 1855, No. 260, appears a short letter from me "On Injections into the Uterus in Cases of Hæmorrhage after Delivery." If the treatment I there suggested had been followed I am convinced few cases would have succumbed. It is far superior to tournaquets, douches, or the more barbarous custom of passing the hand into the uterus to remove a clot. The force of the fluid injected into the uterus by the syringe will dissolve any clot, and stimulate the contraction of the organ as much as the application of the hand. Cold water, iced water, or vinegar, is easily thrown up. Let the forefinger of the left hand be passed into the os-uteri, and the tube of Weiss's syringe inserted and retained there, an assistant injecting with some force the requisite liquid. I have, within a short time, attended two cases of uterine hæmorrhage. One with Mr. Cooke, the tube was passed up as I directed, and vinegar and cold water injected, which almost immediately arrested the discharge, although symptoms of sinking were alarming. The patient rapidly recovered. The other case I attended with Dr. Lever—hæmorrhage had been going on for some days, and the usual remedies had been tried without effect. A solution of lunar caustic was injected into the uterus with perfect success, and the patient, although in a very reduced state, did well. It is my hope that every Medical man in midwifery practice, especially in the country, will go provided with a powerful syringe and tube.

I am, &c.

SEPTIMUS WRAY, M.D.

Tudor Lodge, Brixton, Dec. 21, 1857.

### AMPUTATION OF THE TONGUE.

[To the Editor of the Medical Times and Gazette.]

In your notice of Mr. Syme's case of amputation of the entire tongue, allow me to direct your attention to the two following circumstances:—

1. I have received a letter from an old friend, Mr. Lister, Mr. Syme's son-in-law, and Assistant-Surgeon to the Royal Infirmary, in which he writes:—"Mr. Syme's reason for removing the tongue bodily was not the extent of the disease, but the uniformly unfavourable result of operations, in which a portion of that organ is taken away."

2. That at page 39 of a little tract, entitled "Illustrations of the Pathology of Cancer," which Mr. Laurence published a year ago, I observe,—“It becomes a question whether complete removal of the tongue and lips, although an operation of extreme severity, would not be more in accordance with the principles of surgery, than any partial operation on those organs.”  
I am, etc. F.R.C.S.

### THE ARTIFICIAL TYMPANUM.

[To the Editor of the Medical Times and Gazette.]

SIR,—In your Journal, at page 614, my treatment is thus decried by Mr. Toynbee. He says: “If Mr. Yearsley desires it, I will give him formally the name of a Physician who consulted me with symptoms of inflammation of the dura mater, from having the cotton wool pushed into the meatus by Mr. Yearsley’s own hands.” In my reply, at page 641, I contented myself with a simple denial of this bold assertion, and a promise to prove it untrue. Now to my proof.

To JOSEPH TOYNBEE, Esq.

SIR,—As I have never seen any accident or injury to my patients from the introduction of the wetted cotton, after many years’ experience, I will thank you, agreeably to your offer in the *Medical Times and Gazette* of this week, to give me the name of the Physician who you say consulted you, “with symptoms of inflammation of the dura mater, from having the cotton wool pushed into the meatus by Mr. Yearsley’s own hands.”

I am, Sir, your obedient Servant,  
15, Savile Row, Dec. 14. 1857. JAMES YEARSLEY.

Mr. Toynbee presents his compliments to Mr. Yearsley; and the physician’s name is Dr. ———, who wrote, Mr. Toynbee believes, on . . . . .  
18, Savile-row, Dec. 15th.

To DOCTOR ———

MY DEAR DOCTOR,—I am accused by Mr. Toynbee of having produced symptoms of inflammation of the dura mater, by introducing the wetted cotton into your ear, and thus endangering your life. Now, I am myself quite sure that this is a most unwarrantable exaggeration of the facts of the case, and I fully rely on your relieving me of such an imputation, and my simple, harmless remedy, of such serious results. After fifteen years’ extensive use of it, I have never seen it do harm, though occasionally a slight irritation, as stated in my pamphlet, attends its first adoption.

If I recollect rightly, you suffered this irritation, but never to any serious degree, nor sufficient to confine you to your chamber; and I believe after it had passed off we again introduced the cotton with success as regarded the otorrhoea which annoyed you.

I am, my dear Sir,  
Most truly yours,  
15, Savile-row, Dec. 17, 1857. JAMES YEARSLEY.

December 22nd, 1857.

MY DEAR YEARSLEY.—A few days before I left London at the time to which you refer, I had a visit from an old Medical friend, and when he found me almost deaf in both ears, and also that I had lost all hope of recovery, he most earnestly advised me to consult Mr. Toynbee before I returned to ———. I promised to do so, and more to please my friend than from any hope of benefit, I called once—and only once—on that individual. He examined me most minutely, and I answered the many questions he put to me. I may have told him that I had tried the cotton plug, and also that I had been obliged to give it up on account of the increase of pain, but to the best of my recollection I did not mention your name, and most certainly I did not say one word about symptoms of inflammation of the dura mater, because at that time I had not the slightest fear of any such result, neither had I the slightest fear that my life was in danger. I am quite sure that I did not say so to Mr. Toynbee, and if he says that I did, I can only consider it as a sad proof of the length to which some Medical men are willing to go when they wish to injure a successful rival in their Medical trade. Please to let me know when and to whom it was that Mr. Toynbee has brought me forward as an evil witness against one from whom

I have received so much kindness, and to whom I feel the greatest gratitude for benefits received.

Believe me, your sincere friend,  
To James Yearsley, Esq.

I make no comment, but leave your readers to draw their own conclusions from the foregoing correspondence.

I am, &c. JAS. YEARSLEY.  
15, Savile-row, Dec. 29, 1857.

### DIFFICULT LABOUR FROM STONE IN THE BLADDER.

[To the Editor of the Medical Times and Gazette.]

SIR,—The following case may be interesting to your readers, on account of its rarity and successful termination. I was sent for in March last by the midwife in attendance on a woman about 22 years old, in consequence of some obstruction to the progress of the labour. On examination I found a hard substance pressing on the superior surface of the vagina, and beyond it I could plainly distinguish the head of the child. After numerous inquiries, the girl confessed that nearly six years previously she had passed a hair-pin up the urethra, where it remained, causing her considerable pain and difficulty in micturition, the urine being occasionally bloody and thick.

The labour rapidly progressing, I raised the tumour, which was moveable, above the pubes, and the child was soon delivered. Immediately afterwards I passed a catheter and detected a stone.

On the 24th of May last, 57 days after delivery, Mr. Coulson having occasion to come into this neighbourhood, I asked him to examine the patient and to remove the calculus. The patient being placed under the influence of chloroform, two ounces of water were injected into the bladder. A litho-trite was introduced, but the blades could not be expanded sufficiently to embrace the stone. A pair of long narrow lithotomy forceps was then introduced, the stone was crushed without difficulty, and a considerable quantity of detritus was brought away. By successive introductions of these forceps the whole of the stone was crushed and brought away. The bladder was then washed out, and during this step a sound was heard, as if the catheter were rubbing against a metallic body. The bladder was then again examined, and a hair-pin was felt lying transversely along the floor of the bladder. Mr. Coulson experienced some difficulty in extricating the hair-pin, which had as it were to be turned in the bladder, so that its long axis might be brought in the direction of the urethra. The hair-pin was an ordinary double one, measuring two and a half inches in length, and was but slightly rusted or injured.

The stone, which was composed of phosphate of lime, weighed two ounces and a half.

Very little irritation followed the operation, and at the end of two months the girl was quite well. She has no pain in the bladder or difficulty in passing or retaining her urine; and on examination with a sound, nothing abnormal is detected, and she remains well up to the present date.

I am, &c. RICHD. RICKMAN SHILLITOR.  
Hitchin, Dec. 28, 1857.

### REPORTS OF SOCIETIES.

#### THE PATHOLOGICAL SOCIETY.

TUESDAY, DECEMBER 15.

Dr. WATSON, President, in the chair.

(Continued from page 645.)

#### Dr. WILKS exhibited a specimen of ULCERATED LARYNX IN TYPHOID FEVER, PRODUCING GENERAL EMPHYSEMA.

It was thought to exemplify an occasional complication of typhoid fever. The case was that of a boy who lately died under Dr. Addison’s care in Guy’s Hospital. About the 12th day of his illness, his neck was observed to be emphysema-

tous, and in a few hours the face, arms, and chest were in a like condition. This continued for ten days, when he died. Besides the usual affection of the ileum, there was found at the back part of the larynx a sloughing ulcer, which communicated with a space between the œsophagus and trachea; through this the air had penetrated into the mediastinum, and so to the general subcutaneous tissue of the body. Considering the rarity of emphysema from such a cause the case might be thought to be unique or accidental, but (Dr. W. believed) for various reasons it was probably not so. In the first place, emphysema had been alluded to by various writers as an occasional occurrence in typhoid fever, though the cause was unknown; and secondly, a peculiar disease of the larynx had been described by various pathologists as a part of typhoid fever: in all probability, then, these two affections stood in the relation of effect and cause; and, therefore, although this was the first case he had witnessed it appeared in all likelihood an explanation of an occurrence which rarely, though sometimes, happens in the course of typhoid fever.

Dr. WILKS also exhibited a

#### HEART CONTAINING A FEW CANCEROUS DEPOSITS,

and stated that such a specimen had occurred in his own experience only once in several hundred cases of carcinomatous disease. It was secondary, and the nodules of deposit were very small.

Also the

#### KIDNEYS, IN A CASE OF BRIGHT'S DISEASE,

which together weighed less than 1½ ounce. These were the smallest organs he had ever seen.

After a vote of thanks to the exhibitors, the meeting concluded.

At a former meeting of the Society, Dr. VAN DER BYL exhibited a specimen of

#### OBSTRUCTION OF THE CEREBRAL ARTERIES BY FIBRINOUS PLUGS, IN CONNEXION WITH VEGETATIONS ON THE AORTIC AND MITRAL VALVES.

This was an uncommonly well-marked case of obstruction of the cerebral arteries by fibrinous plugs, and occurred in a woman aged 44. On examining the vessels at the base of the brain, fibrinous plugs were discovered in the basilar artery, in the anterior, middle, and posterior cerebral arteries of the right side, and in the middle cerebral artery of the left side. The plugs were situated at the bifurcation of the basilar artery, and in the other vessels at points where large branches were given off. Beyond each plug, and more or less continuous with it, there was a coagulum, which extended some distance, and was partially decolorized; but these coagula were not so firm and white, as (what may be termed) the original plugs. On slicing the brain two patches of red softening, about the size of nuts, were observed, and these contained compound granular corpuscles. The heart was fatty: the aortic and mitral valves were covered with warty vegetations, which were very easily detached, and seemed peculiarly friable. On being examined with the microscope the fibrinous plugs in the cerebral arteries were found to be exactly similar in structure with the vegetation on the mitral valve, and both consisted of granular and molecular matter, along with cells resembling the white corpuscles of the blood. The kidneys and spleen contained large masses of fibrinous deposit. The uterus was enlarged, and its posterior lip thickened; it resembled the uterus of a person who had recently suffered a miscarriage. The history of this patient is briefly as follows:—About three months before death, when in good health, she was seized with giddiness, and fell down. She was unconscious for about ten minutes, and on regaining her intellect, found that she had lost the use of her left side, and that she had rather copious hæmorrhage from the womb. A week after this she was admitted into the Middlesex Hospital; the uterine hæmorrhage was still free, but there was no abdominal pain or tenderness. She was sensible, and could answer questions rationally, but there was total loss of power in the left arm and leg, and the face was drawn to the right side. The evacuations were passed involuntarily, and she was troubled with vomiting. In the course of three days the uterine

hæmorrhage gradually subsided, and she regained sufficient power over her left leg to draw it up, and to stand with assistance. The face was still drawn to the right, and the left arm powerless. The sickness now became more frequent; she was sensible of a disposition to evacuate the bowels, and could retain the motions for a short time; she could also evacuate the bladder. These symptoms continued with little alteration for a week, and until thirty-six hours before death she remained quite sensible. She then became suddenly worse; stertorous respiration came on, and she died comatose.

THE PATHOLOGICAL SOCIETY OF LONDON.—The following is the list of officers proposed for election for the year 1858. The gentlemen whose names are marked with an asterisk (\*) did not hold the same office during the preceding year.—*President*, Thomas Watson, M.D. *Vice-Presidents*, William John Little, M.D.; James Risdon Bennett, M.D.; \*Benjamin Guy Babington, M.D., F.R.S.; \*C. J. B. Williams, M.D., F.R.S.; James Moncreiff Arnott, Esq., F.R.S.; William Fergusson, Esq., F.R.S.; John Simon, Esq., F.R.S.; \*George Busk, Esq., F.R.S. *Treasurer*, Richard Quain, M.D. *Council*, William Baly, M.D., F.R.S.; John Syer Bristowe, M.D.; William Camps M.D.; Thomas Harrington, Tuke, M.D.; Theophilus Thompson, M.D., F.R.S.; Samuel Wilks, M.D.; \*Thomas Bevell Peacock, M.D.; \*John Clarke, L.R.C.P.; \*A. Whyte Barclay, M.D.; \*Lionel S. Beale, M.D., F.R.S.; John Morgan, Esq.; William Augustus Hillman, Esq.; Jonathan Hutchinson, Esq.; John Cooper Forster, Esq.; John Wood, Esq.; Thomas Blizard Curling, Esq., F.R.S.; \*Alexander Shaw, Esq.; \*George Critchett, Esq.; \*John James Purnell, Esq.; \*J. Charles Langmore, Esq. *Honorary Secretaries*, John William Ogle, M.D.; Mitchell Henry, Esq.

#### CHEMICAL SOCIETY.

At a recent meeting of this Society a paper was read by Dr. MARCET, on the

#### FATTY MATTERS OF HUMAN EXCREMENTS IN DISEASE.

It has often been noticed that excessive quantities of fats are voided by the motions in certain diseases; but no attempt having been made to separate these fatty substances from each other, and obtain them in the form of Immediate Principles, I have undertaken this task in one case, by adopting a method of investigation similar to that which I had made use of for the analysis of healthy excrements. The case in question is that of a man who was for a long time my patient at the Westminster Hospital, labouring apparently under disease of the kidneys. From his excessive emaciation, it was evident that the assimilation was very defective, and with the view of endeavouring to obtain some further insight into the nature of the disease, his fæces were submitted to examination. They had the consistence of putty, a yellow grey colour, and a strongly acid reaction. When boiled with alcohol, they formed an homogeneous mass, which, being squeezed in a muslin bag, yielded a turbid alcoholic fluid; this was now filtered through filtering paper, and the insoluble residue exhausted with boiling alcohol. On cooling, an abundant crystalline deposit, quite free from colouring matter, occurred in the solution. In order to analyse the deposit, it was collected on a filter, and the filtrate was left to evaporate spontaneously. I removed the deposit to a flask, and then treated it with ether, until nothing more was dissolved; by so doing, the crystalline mass was divided into a substance insoluble in ether, and one which was soluble in this fluid. The substance insoluble in ether dissolved in hot alcohol, but was sparingly soluble in cold alcohol; the solution had an acid reaction. The crystals were soluble in hot water; but the addition of cold water to the alcoholic solution induced the formation of a cloudy precipitate, and the fluid gradually became neutral. This compound fused at a temperature ranging between 100° and 103° C. When the aqueous solution was mixed with hydrochloric acid, the liquid deposited white flakes; these were collected on a filter, and the acid filtrate being evaporated to dryness, left a residue, which did not clear on the

application of a strong heat, and was found to consist of nothing but chloride of sodium. The white precipitate being washed with water till the washings ceased to give a precipitate in a solution of nitrate of silver, was treated with ether, when it dissolved, resuming its crystalline form by spontaneous evaporation; the crystals were also soluble in hot alcohol. They fused at  $66^{\circ}\text{C}$ . and reappeared at  $64^{\circ}\text{C}$ . When burnt on a platinum spatula, this substance charred, ignited, and left no residue. In short, there could be no doubt that it was stearic acid; consequently, it appeared very probable that the original compound insoluble in ether was the *bistearate* or the *stearate of soda*. The fact was placed beyond doubt by a quantitative analysis of the substance. For this purpose a sample of the compound, thoroughly exhausted with ether, was dried over sulphuric acid under the air-pump until it ceased to lose weight; it was then found to weigh 0.275 grammes. The substance was now dissolved in hot water (being insoluble in cold water), and decomposed with hydrochloric acid in excess, when an abundant flocculent precipitate of fatty acid occurred. The precipitate collected on a filter, and washed with distilled water (till the washing ceased to produce a haziness in a solution of nitrate of silver), was removed into a weighed watch-glass, to be dried over sulphuric acid under the air-pump. In order to avoid losing a trace of the fatty acid, the filter itself was treated with ether, and the solution evaporated to dryness in a weighed watch-glass, which, when dried under the air-pump, gave only 0.006 grammes of the substance. The whole weight of the perfectly dry fatty acid was 0.259; therefore, 0.275 grammes of the compound submitted to analysis consisted of

0.259 grammes of stearic acid,  
and 0.016 grammes of soda.

0.275

or, 100 parts contained

94.18 of stearic acid,  
and 5.82 of soda.

100.00

Chevreul found 100 parts of *bistearate of soda* to consist of

Stearic acid . . . 94.33  
Soda . . . . . 5.67

100.00

Consequently, the substance under examination was *bistearate of soda*.

It is the first time, I believe, that *bistearate of soda* has been extracted directly from the animal body, and, consequently, in the form of an Immediate Principle. Its separation from the other fatty acids is very easy, on account of the circumstance that this compound is insoluble in ether; and it is readily distinguished from the other soaps by its property of crystallising in a concentrated alcoholic solution as soon as the fluid has become cold, whilst the other compounds of fatty acid and soda solidify from their solution in alcohol, in the form of a gelatinous deposit, which crystallises on standing, after some time has elapsed. *Bistearate of soda* was first obtained by Chevreul by dissolving one part of stearate of soda in 2,000 or 3,000 parts of hot water, filtering the liquor when cold, washing the deposit, drying it and treating it with hot alcohol; the solution, when cold, deposited *bistearate of soda*. (a)

In no case have I detected this compound as an Immediate Principle of healthy human evacuations; it is, consequently, a morbid product, resulting, in all probability, from the action of abnormally large quantities of free acids in the intestinal canal: the very acid reaction of the excrements supports this view. Healthy human feces yield margarate of lime and margarate of magnesia; if they contain any soda or potash soda at all, it must be in very small quantities. Free fatty acids do not exist in healthy human evacuations, unless a comparatively large amount of vegetable food has been taken; and in these cases I have not detected the presence of any *bistearate*.

The excrements in the present instance yielded not only *bistearate of soda*, but a considerable quantity of free fatty acids, which most probably depended, as I shall presently

show, on the functions of the pancreas and liver being arrested.

The alcoholic filtrate from the *bistearate of soda*, gave on standing another crop of crystals, consisting of a mixture of *bistearate of soda* and of fatty acid. By treating these various deposits with ether, a substance was dissolved which crystallized by spontaneous evaporation, and proved to be a mixture of stearic and margaric acids, the former being in excess. The crystallised deposit possessed the following characters. The crystals occurred under the form of small white masses, exhibiting under the microscope groups of needles radiating from the centre to the periphery. They fused at a temperature of  $60^{\circ}\text{C}$ , which, according to Gottlieb, corresponds to a mixture of eighteen parts of stearic with ten parts of margaric acid; they were soluble in cold ether and in hot alcohol, and insoluble in water; the substance dissolved in potash and could be precipitated in this alkaline liquor by means of hydrochloric acid; when heated on the platina-knife, the crystals fused, ignited, and finally left no residue. These characters are precisely those of the above-mentioned fatty acids: the amount of the mixture at my disposal did not allow of the complete separation of these acids being effected.

The clear alcoholic fluid being allowed to stand undisturbed for twenty-four hours, yielded another crop of beautifully white glistening crystals. These were submitted to examination, and proved to be *margaric acid*, apparently free from stearic acid. These crystals dissolved in ether and hot alcohol, and crystallised from these solutions; the ethereal and alcoholic fluids had an acid reaction; the substance was insoluble in water, but dissolved in aqua potassæ. Hydrochloric acid induced its precipitation from the alkaline liquor. It fused at  $53^{\circ}\text{C}$ ., and crystallised, on cooling, at  $49^{\circ}$ , this low fusing point being due probably to the admixture of a small quantity of oleic acid; the crystals occurred in the form of small radiating masses peculiar to margaric acid; they burnt with a fuliginous flame, leaving no trace of ashes.

The occurrence of such quantities of fatty acids in this case being considered in connexion with the condition of the body of the patient, is of great interest, not only in a chemical but also in a physiological and pathological point of view. The pancreas of the patient was found at a post mortem examination entirely disorganised by malignant disease, and it apparently so compressed the duct of the gall-bladder that no bile could flow into the intestines. Consequently the two alkaline intestinal secretions were wanting, and the fatty acids contained in the alimentary canal could not be neutralised. This is an important fact in favour of Bernard's view respecting the properties of the pancreatic juice.

I avail myself with pleasure of this opportunity to acknowledge the valuable aid I have received from my assistant, Dr. Frederick Dupré, in these and other investigations.

## THE NEW MEDICAL CHARITIES BILL.

THE following is a short abstract of this Bill:—It is entitled—“A Bill to amend the Laws in force for the Relief of the Destitute Poor in Ireland, and to amend an Act of the 14th and 15th years of her Majesty, providing for the better Distribution, Support, and Management of Medical Charities in Ireland.”

The preamble sets forth that “It is expedient to amend the laws in force for the relief of the destitute poor in Ireland, and to amend an Act passed in the session holden in the 14th and 15th years of her Majesty, chap. 68, providing for the better distribution, support, and management of Medical Charities in Ireland.”

Clause 1 provides that lands and property heretofore vested in the Commissioners, shall be vested in Boards of Guardians, subject to the orders of the Commissioners; and also that Boards of Guardians “shall, for this purpose, as well as for other purposes set forth in the said Acts, be deemed Bodies Corporate, holding the said property, subject in all respects to the orders of the said Commissioners.”

Clause 2 extends in-door relief to persons not paupers. Here is the clause:—

“And whereas the guardians of the poor of unions in Ireland are empowered to admit into any building provided by them for a fever hospital, or into any part of the workhouse

(a). Recherches Chimiques sur les corps gras d'origine animale. Par M. L. Chevreul.

appropriated by them, with the consent of the Commissioners for that purpose, poor persons affected with fever, or other dangerous contagious disease, and it is expedient to extend such power: be it enacted, that it shall be lawful for such guardians to admit into the infirmary of the workhouse any poor persons requiring medical or surgical aid in hospital, and to provide for their treatment and maintenance therein, charging the expense thereof on the electoral division or union, as the case may be."

Clause 3 is a curious illustration of the self-supporting principle:—

"Every poor person who shall be so admitted into the infirmary of the workhouse, in pursuance of the authority in that behalf which is hereinbefore given, and every poor person who shall hereafter be admitted into any building provided by the guardians of any union for a fever hospital, or into any part of the workhouse appropriated as a fever hospital, who shall nevertheless be considered by the guardians to be of sufficient ability to pay the cost of his or her maintenance while in hospital, or some portion of such cost, shall be required to repay such proportion thereof as the guardians shall determine, provided that such proportion shall in no case exceed the average of the general cost of maintenance in such hospital or infirmary; and all such sums shall be recoverable from such poor persons, or from those liable by law to maintain them, by the same ways and means as the cost of relief given by way of loan is recoverable under the Acts in force for the relief of the destitute poor in Ireland."

The constabulary force is also to have the benefit of this provision for the medical care of the people, according to clause 4.

Clause 5 provides that persons taking the benefit of this 4th Clause shall not be disfranchised, as having received relief from the poor rates.

Clause 6 enables the Governors of General Hospitals and County Infirmarys to take cases from the poorhouses, "and to pay to the governor or governors of such hospital out of the rates of the union the cost of the maintenance and treatment in such hospital of the persons so sent as aforesaid, and the guardians may also pay out of the rates of the union the cost of the conveyance of such persons from the workhouse of the union to such hospital, and also the cost of the conveyance of such persons, when discharged from such hospital, to the said workhouse."

The 7th Clause is the only other one requiring notice at present. The measure, on the whole, is tolerably good.

"And whereas it has been found that the mortality among infant children admitted into workhouses without their mothers is very large, and that in other respects the workhouses are not well suited in all cases for the care and nurture of such children during infancy, and it is therefore expedient to extend the powers of Boards of Guardians for the relief of destitute poor children who are orphans, or who have been deserted by their parents: be it enacted, that it shall be lawful for the Board of Guardians to provide for the relief of any orphan or deserted child out of the workhouse, if they shall think fit to do so, by placing such child out at nurse, or otherwise, according to their discretion; provided, that no child shall continue to be so relieved after the age of five years."

## MEDICAL NEWS.

**ROYAL COLLEGE OF PHYSICIANS.**—At the usual quarterly meeting of the Comitia Majora held on Tuesday, the 22nd inst., the following gentlemen having undergone the necessary examinations, were admitted members of the College:—

Dr. WALLACE, 5, Green-terrace, Clerkenwell.

Dr. GATTON, St. Bartholomew's Hospital.

Dr. REED (an extra-licentiate), 46, Hertford-st., Mayfair.

Dr. CHAPMAN, 62, George-street, Portman-square.

Also, Dr. Mawer, late of Abbey-road, St. John's-wood, was admitted an Extra-Licentiate.

**ROYAL COLLEGE OF SURGEONS.**—The following Members of the College, having undergone the necessary examina-

tions, were admitted Fellows at the last Meeting of the Council:—

AUSTEN, JOHN COLMER, Ramsgate, diploma of membership dated April 21, 1845.

CUTCLIFFE, HENRY CHARLES, Dulwich, May 5, 1854.

HARRIS, WILLIAM, Waterford, March 10, 1854.

LAWSON, GEORGE, Park-st, Grosvenor-sq., Aug. 9, 1852.

The following gentlemen, having undergone the necessary examinations for the diploma, were admitted Members of the College at a meeting of the Court of Examiners on the 21st ult.:—

CHEYERS, CHARLES EDWARD, Jamaica.

CUTLER, HENRY, Droitwich, Worcestershire.

HARVEY, CHARLES HAMILTON, Clarendon-rd, Notting-hill.

HUGHES, RICHARD, Euston-square.

LONGMORE, CHARLES, Army.

NORTON, SELBY, West Malling, Kent.

O'DONOVAN, THOMAS PETER, Southend.

POUGNET, FRANCOIS VOLCT, Mauritius.

ROGERS, OWEN OSSIAN, Stonehouse, Plymouth.

WATTS, WILLIAM HENRY, Army.

WHITAKER, HENRY, Belfast.

WHITE, CHARLES WILLIAM, H.E.I.C.'s Service, Madras.

**APOTHECARIES' HALL.**—Names of gentlemen who passed their examination in the Science and Practice of Medicine, and received Certificates to Practise, on Dec. 24:—

BRUNTON, WILLIAM RIDDELL, East Indies.

DIVER, THOMAS, Hampstead.

EDMONDS, SHIRLEY, Woolmer.

EDWARDS, WILLIAM WATKIN, Keston.

ETTERMARCK, GEORGE, Guernsey.

HARRISON, JOHN, Gibraltar.

KEENE, ALFRED WILLIAM, Guildford, Surrey.

PAGE, EDWARD ARTHUR, Bedworth, Warwickshire.

PARKINSON, GEORGE, Grosvenor-street.

WHITE, GEORGE FARR, Park-terrace, Regent's-park.

## DEATHS.

**BAKER.**—On the 22nd ult., at Staines, James Baker, M.R.C.S., 1821; and L.S.A., 1828, in the 57th year of his age.

**FOSS.**—On the 29th November last, on board the Royal Mail Steamship Parana, on passage from Jamaica to England, Thomas Foss, 1st Class Staff Surgeon to the Forces.

**HAWES.**—On the 16th ult., William H. B. Hawes, M.R.C.S., Eng., 1835; Surgeon Royal Society of Musicians, and Roy. Hum. Society; second son of the late Wm. Hawes, Esq., of 7, Adelphi-terrace.

**LAYMAN.**—On the 24th ult., at Shefford, Beds, where he had been in extensive practice for 30 years, James Milner Layman, L.S.A., 1822, aged 55, formerly of the Spanish Legion.

**SULLIVAN.**—Of yellow fever, on the 1st of November, at the Naval Hospital, Jamaica, Daniel O'Connell O'Sullivan, Assistant-Surgeon in the Royal Navy, son of Dr. O'Sullivan, of Clane, County Kildare. Every tribute of respect was paid to his remains, not only by the crew of his own ship, but of every vessel in the harbour, affording abundant proof of the estimation in which he was held.

The following names appear in the last list of the killed and wounded in India:—Gualior Contingent, K. W. Kirk, M.D., Superintending Surgeon, 14th June. Mr. Sadler, Sub-assistant Surgeon, Kotah, 15th October. Mr. Neilson, Veterinary Surgeon, 10th August, throat cut from ear to ear by the mutineers of the 10th Cavalry. Dr. J. Graham, Superintending Surgeon. Dr. J. C. Graham, Medical Storekeeper, Sealkote, 9th July, shot dead by mutineers of the 9th light Cavalry, in their carriages, in presence of their female relatives. Veterinary Surgeon Phillips, Veterinary Surgeon Dawson, his wife and children, 3rd light Cavalry. Dr. Christie, 3rd light Cavalry, wounded at Meerut, 10th May. Dr. Hay, Bareilly Division, 31st May. Dr. Lyell, shot on the night of the 3rd July, Patna. Assist. Surgeon N. J. Grant, attached to Irregular Cavalry, wounded. At Rohnce, in the Southal Pergunnahs, 12th June. Assist. Surgeon H. S. Garner, 12th Irregular Cavalry, and Mrs. Garner and child killed:—the mutineers, after killing Major Holmes, proceeded to the

Doctor's bungalow, forced it open, murdered the doctor, his wife, and one child, and then set fire to it. One child, a little girl, escaped notice, and was taken care of by the Tehsildar, at Segowlee, July 23rd. At Lucknow, Royal Artillery, Assist. Surgeon Neale, wounded severely.

WE are happy to state that Dr. B. W. Richardson has just been elected an honorary member of the Literary and Philosophical Society of St. Andrews. He was proposed by Professor Day, who laid great stress on Dr. Richardson's double claim to this honour, both as one of the most successful experimental physiologists of the age, and as one of the most active promoters of Sanitary science. Dr. Richardson graduated at St. Andrews in 1854. Dr. Richardson was also elected, on Nov. 16, 1857, a corresponding member of the Society of Scientific Medicine of Berlin.

THE MURRAIN.—The following are the conclusions of Professor Simonds, appended to a most able and valuable report on the Cattle Plague, a copy of which we have just received, and shall notice more fully on some future occasion.

"1. That all the countries of Northern and Western Europe from which cattle are exported to England are perfectly free from the rinderpest; and that the only disease of an epizootic or destructive nature which prevails therein is the one known to us as pleuro-pneumonia—which disease has existed here since 1841.

2. That in the greater part of the official despatches and reports which have been forwarded to the Government, and by them transmitted to the Royal Agricultural Society of England, the rinderpest has been confounded with pleuro-pneumonia, "milzbrand," and other destructive maladies to which cattle are liable.

3. That the rinderpest is a disease which specially belongs to the Steppes of Russia, from which it frequently extends in the ordinary course of the cattle trade into Hungary, Austria, Galicia, Poland, &c.

4. That whenever circumstances have arisen which called for the movements of troops and consequently the transit of large numbers of cattle in Southern and Eastern Europe, and particularly when Russian troops have crossed the frontier of their territory, the disease has been spread over a far greater extent of country.

5. That the disease which has recently prevailed in Galicia—where it was specially investigated by ourselves—as well as in Poland, Austria, Hungary, the Danubian Provinces, Bessarabia, Turkey, &c., is the true rinderpest or Steppe Murrian of Russia.

6. That with the exception of a few places in the kingdom of Prussia and others in Moravia, near to the frontier of Galicia and Poland, the disease in its outbreaks of 1855, 1856, and 1857, did not extend to any country lying westward of a line drawn from Memel on the Baltic to Trieste on the Gulf of Venice.

7. That speaking in general terms rinderpest has not existed in Central and Western Europe for a period of forty-two years; its great prevalence at that time being due to the war which was being then carried on between the different continental kingdoms and states.

8. That all the facts connected with the history of its several outbreaks concur in proving that the malady does not spread from country to country as an ordinary epizootic. And that if it were a disease exclusively belonging to this class, the sanitary measures which are had recourse to throughout Europe would be inefficient in preventing its extension, and consequently, that in all probability we should long since have been both painfully and practically familiar with it in this country, as hundreds of our cattle would have succumbed to its destructive effects.

9. That it is one of the most infectious maladies of which we have any experience, and that it is capable of being conveyed from animal to animal by persons, and various articles of clothing, &c., which have come in contact with the diseased.

10. That the ox tribe is alone susceptible to the disease: and that the morbid matter on which it depends lies dormant in the system for a period of not less than seven days, and occasionally, according to some continental authorities, as long as twenty days before the symptoms declare themselves.

11. That an attack of the disease which has terminated

favourably renders the animal insusceptible to a second action of the *materies morbi* which gives origin to the pest.

12. That the deaths often amount to 90 per cent.

13. That the malady is one in which the blood is early, if not primary affected; and that subsequently the mucous membranes throughout the entire body become the principal seat of the morbid changes.

14. That the symptoms are in general well marked and quite characteristic of the affection.

15. That all varieties of medical treatment which have as yet been tried have failed in curing the disease; the recoveries which take place having for the most part depended on the *vis medicatrix nature*.

16. That no fear need be entertained that this destructive pest will reach our shores. Its present great distance from us would, of itself, afford a fair amount of security; but when we add to this that no cattle find their way from thence directly or indirectly to the English market, and also that in the event of the disease spreading from Galicia, it would have to break through hundreds of military cordons, one after the other, before it could possibly reach the *western side* of the German states; and, moreover, that for years past commerce has been unrestricted with regard to skins, hides, bones, &c., of cattle from Russia and elsewhere, all alarm, we believe, may cease with reference to its importation into the British Isles."

SCARLATINA IN SCOTLAND.—Scarlatina has been fatally prevalent in Perth, but is now on the decline there. It has broken out, however, in the Lochee Registration District of Dundee, to which it is at present nearly confined. It is worthy of being noticed, as showing the connexion between the progress of all epidemics, that the side of Dundee in which the disease has appeared is that through which the road from Perth passes.—*Northern Warder*.

REVACCINATION OF THE FRENCH ARMY AND NAVY.—A proposal, with this object in view, is now under the consideration of the Minister at War.

PRIZES AT THE ACADEMIE DE MÉDECINE FOR 1857.—The Academy prize of 1000 francs, the Portal prize of 1000 francs, the Lefevre prize of 1800 francs, and the Barbier prize of 3000 francs have neither of them been adjudged this year, either in consequence of want of candidates or of deficiency in merit in the essays offered. On the other hand, for the Argenteuil sexennial prize of 12,000 francs, for the greatest improvement in the treatment of stricture, during the period from 1850 to 1856, no less than 22 essays have been sent in, so that the committee is obliged to put off its report till next year. The Civrieux prize of 1600 francs, subject "Nervous vertigo," has been adjudged to M. Max Simon; the first Capuron prize of 1000 francs, subject, "Sudden death in the puerperal state," has been adjudged to M. Mordret; and the second Capuron prize, also of 1000 francs, subject, "Saline mineral waters," has been adjudged to MM. E. Petrequin and Socquet, both professors at Lyons.

At a meeting of the Medical Society of Christiania, held on the 16th of December last, Dr. W. D. Moore, of Dublin, was unanimously elected a Foreign (honorary) Member of the Society. This compliment has been well merited by Dr. Moore's zeal and interest in making the Medical literature of Norway known wherever the English language is read.

## VITAL STATISTICS OF LONDON.

Week ending Saturday, December 26, 1857.

## TO CORRESPONDENTS.

*M. P. S.*—As the patient becomes strong the testicles usually recover their former size.

*Mars.*—Fownes's Manual is the best.

*M. D.*—The Metropolitan Life Assurance Society have recently come to the decision to allow fees for replies to the inquiries addressed to the professional referees.

*Dr. M'Donnell.*—The case is marked for publication, but several others claim priority, having been much longer in our possession.

*An Associate of King's College, London.*—We shall be happy to publish the letter with the author's name, but it would not be fair to do so anonymously.

We have made inquiries respecting the card of the *L. R. C. P.*

*F. R. S.*—Chevreul certainly deserved the Copley medal. His investigations have taught us how to procure hard valuable fats from poor cheap oils, and thus opened up a new branch of profitable national industry.

*Meteorologist.*—It has been computed that on the 22nd of October last, 20,000,000 tons of rain-water fell on the 78,000 acres included in the Registrar-General's returns. This gives in one day more than a tenth of the entire annual rainfall.

*Naturalist.*—Government are about to send out an expedition to explore the Zambesi.

*Mr. S.*—As the case of alleged neglect at Bridgewater has terminated in the extraordinary verdict, "Died from Natural Causes," it seems unnecessary to comment on the details. Boards of Guardians must pay their Medical officers better, before they can insist upon more frequent attendance on paupers than is really necessary.

## THE POLYTECHNIC.

The Christmas entertainments at this Institution are remarkably good. The new bread-making machine of Mr. Stevens is shown; a number of ingenious railway signals, and other recent mechanical inventions. Views of the sites of the recent events in India are accompanied by an admirable descriptive lecture; and a curious lecture on natural magic lays bare the mystery of several of the best conjuring tricks. The place is well worth a visit.

## URINARY DEPOSITS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I was much surprised on having my attention directed to the report of a County court case which lately appeared in *The Times*. In it a Medical Gentleman of some standing is stated to have said "that it is quite impossible to determine the nature of certain deposits in the urine under twelve or fourteen hours at the very least." In refutation I beg to draw the attention of such of your readers as may take an interest in the matter, to a paper published in your Journal so far back as the 25th January, 1851, in which the author, Dr. Venables, has pointed out a means by which any of the sediments in the urine may be detected, and their nature ascertained by the microscope, in at most two or three seconds.

For the detail I refer to the paper, and beg to state that I have practised the method ever since, and have not failed or been disappointed in a single instance.

I am, &c.

B. W.

P.S.—As I have referred to the date you will find the paper in No. 30, new series, p. 86, et seq.

*Philologus.*—At the Arctic College at Irkutsk, a Russian imperial ukase has ordered that the study of German is to be discontinued, and that of English substituted.

## THE SALE OF POISONS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Another remarkable case of poisoning at Glasgow! The particulars of this horrible affair, as reported in to-day's *Times*, need not be repeated here; they will be read and commented on by the public generally. The case, however, in a Medical point of view, must possess unusual interest for your readers. I venture, therefore, to point out one circumstance connected with it to which too much importance cannot be attached, and which cannot gain too much publicity. I refer to the fact of the chemist having supplied the poison not only without sufficient inquiry as to the purpose for which it was purchased, but, as he himself admitted, with a doubt upon his mind as to the credibility of the answer given him to a very careless question on that point.

These facts being elicited on the trial, they called forth some severe remarks of censure from the Judge as to the moral responsibility of the chemist (or his assistant) in this matter.

Now this "moral responsibility" always attaches to the chemist under similar circumstances; but in how many cases does it influence them to be a whit more cautious? Very few, we should say, from the number of instances of poisoning that may be traced to carelessness in dispensing deadly drugs. I do not refer to the carelessness which causes mistakes, but to a want of proper caution, judgment, or discretion, in supplying persons with poisons under doubtful circumstances (as in the case now under our attention). Such cases will be frequent, unless chemists are placed under legal responsibility,—that is to say, they must be liable to arraignment as a culpable party, and be subjected to the decision of a verdict, if not in degree as severe as the principal actor concerned in these fearful tragedies, certainly such a penalty should be inflicted as may seem commensurate to the amount of culpability with which they play their part in these scenes of death.

Trusting that the forthcoming "Bill for restricting the Sale of Poisons" will contain some vigorous clause to the above effect,  
December 28. I am, &c. M. A. B.

## COMMUNICATIONS have been received from—

Dr. CONOLLY; Mr. TOYNBEE; Professor SIMONDS; Dr. G. JOHNSON; Dr. HARE; Mr. PAGET; Mr. WHITE COOPER; Dr. WILLIAMS; Dr. WEBSTER; Dr. JAMES ARNOTT; Mr. BRYANT; Dr. M'WILLIAM; ROY. J. BARLOW; Mr. MUNZIE; Mr. DUFF; Mr. COOPER; Dr. M'DERMOTT; Miss NEVILL; Mr. MARSHALL; Mr. BARKER; Dr. J. RYAN; M.P.S.; Dr. M'DONNELL; Mr. HART; Mr. SHILLTOE; Mr. REED; Mr. EDWARDS; Dr. LEMOINE; Mr. DALE; Mr. MILLARD; Dr. JAMESON; Mr. G. JOHNSTON; Mr. J. CLARKE; Mr. C. B. WILES; Mr. D. HARTLEY; Mr. H. DAYMAN; Mr. R. BATES; Mr. H. GRAVES; Mr. W. HINGESTON; Dr. VERHAEGHE; Mr. G. TOWNS; Mr. W. WOOD; Mr. W. FEW; Mr. R. F. SNAPE; Mr. J. PEARSON; Dr. SCHOLEFIELD; Mr. T. JAMES; Mr. J. TERREY; Mr. G. HOOD; Mr. J. KEAMS.

## APPOINTMENTS FOR THE WEEK.

## Jan. 2. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m. Westminster, 1 p.m.; King's, 2 p.m.; Charing Cross, 1 p.m.

## 4. Monday.

Operations at the Royal Free Hospital, 1 p.m.; Metropolitan Free Hospital, 2 p.m.; Orthopedic Hospital, 3 p.m.

ENTOMOLOGICAL SOCIETY, 8 p.m.

EPIDEMIOLOGICAL SOCIETY.—Mr. Johnson, of Bishop Wearmouth, "On the localized Causes which influence the Arrest or Spread of Cholera."

## 5. Tuesday.

Operations at Guy's, 1 p.m.

PATHOLOGICAL SOCIETY.—(Anniversary), 8 p.m.

## 6. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m.

Orthopedic Hospital, 8 p.m.

PHARMACEUTICAL SOCIETY, 8 p.m.

GEOLOGICAL SOCIETY, 8 p.m.

ROYAL SOCIETY OF LITERATURE, 8½ p.m.

## 7. Thursday.

Operations at St. George's, 1 p.m.; Middlesex, 1½ p.m.; Central London Ophthalmic, 1 p.m.; London, 1½ p.m.

ROYAL SOCIETY, 8½ p.m.

ZOOLOGICAL SOCIETY, 3 p.m.

HARVEIAN SOCIETY, Dr. Sanderson, "On the Nosological Characters of Disease in 1857."

GROSVENOR PLACE SCHOOL MEDICAL SOCIETY, 7½ p.m.

## 8. Friday.

Operations at the Moorfields Ophthalmic, 10 a.m.; Westminster Ophthalmic, 1½ p.m.

## EXPECTED OPERATIONS.

King's College Hospital.—The following operations are expected at this hospital to-day (Saturday), at 2 o'clock:—

Division of stricture (two cases), by Mr. Bowman.

Westminster Hospital.—The following operations will take place at this Hospital next Tuesday, at 2 o'clock:—

Stricture of urethra; necrosis of lower maxilla; polypus uteri; extensive growth from nymphae, by Mr. Holt.

Just published, price 3s. 6d., with 200 Descriptive Cases, and Illustrations in Chromo-Lithography.

## Amputations and Artificial Legs, HANDS, &c. By WILLIAM ROBERT GROSSMITH, of 175, Fleet-street, London.

"Mr. Grossmith has offered some good practical suggestions for the consideration of the operator, and has entered more fully into the subject than has hitherto been attempted."—*Lancet*, Nov. 14, 1857.

"Mr. Grossmith's artificial limbs are well constructed, and on the best system."—*Paris Exposition Jury Reports*.  
London: Longman & Co., Paternoster-row. Dublin: Fannin & Co., Grafton-street: and from the Author, post free

On the First of January, Volume XXVI., Post 8vo, cloth, 6s. 6d.

## Half-yearly Abstract of the Medical

SCIENCES; being a Practical and Analytical Digest of the Contents of the Principal British and Continental Medical Works published in the preceding half-year; together with a Critical Report of the Progress of Medicine and the Collateral Sciences during the same period. London: John Churchill, New Burlington-street.

## To Authors and Publishers.—The

Subscribers, Publishers of, and Dealers in, Medical and Scientific Books in the United States are prepared to make liberal arrangements with the Authors and Publishers of Great Britain for the republication or Sale of their Books. They refer to Messrs. Trübner and Co., Paternoster-row, and Messrs. Sampson, Low, and Co., Ludgate-hill, London, through whom parcels, containing sample copies, proof sheets, or MSS. may be sent.

LINDSAY and BLAKISTON, Publishers, Philadelphia, U.S.

[ESTABLISHED 1841.]

## Medical, Invalid, and General Life

OFFICE, 25, PALL MALL, LONDON.

Empowered by Special Act of Parliament.

By the Annual Report of 1853, it appeared that the number of Policies then in force was 3434, insuring £1,337,500, and yielding an income of £56,307.

At the SIXTEENTH ANNUAL MEETING, held on 26th November, 1857, it was shown that on the 30th June last:—

The Number of Policies in force was .. .. .	6255
The amount Insured was .. .. .	£2,917,598 13s. 10d.
The Annual Income was .. .. .	£125,113 3s. 8d.

Two Bonuses have been declared (in 1848 and 1853), adding nearly Two per cent. per annum on the average to sums assured, and by which a Policy of £1000 issued in 1842 on a healthy life, is now increased to £1260.

Profits divided every five years—next division in 1858.  
The Society, since its establishment, has paid claims on 776 Policies, assuring £319,884.

Assurances are effected at home or abroad on healthy lives at as moderate rates as the most recent data will allow.

Indian Assurances at very moderate rates, and great facilities given to assurers.

Invalid lives assured on scientifically constructed tables.

Policies issued free of stamp duty, and every charge but the Premiums.

Medical men are paid a guinea for each report, and receive the same advantages as Solicitors for any business they may introduce.

Active working agents wanted for vacant places.

Prospectuses, Forms of Proposals, and every other information, may be obtained of the Secretary at the Chief Office, or on application to any of the Society's Agents in the country.

C. DOUGLAS SINGER, Secretary.

Established 1835.

## Family Endowment Life Assurance

AND ANNUITY SOCIETY. Empowered by Special Act of Parliament. Chief Office, 12, Chatham place, Blackfriars, London, E.C. Subscribed Capital—Half a Million Sterling, with an Annual Income of Sixty Thousand Pounds, and an Accumulated Premium Fund of Two Hundred Thousand Pounds.

CHAIRMAN.

JOHN FULLER, Esq., Somerset-place.

DEPUTY CHAIRMAN.

Lieut.-Colonel H. B. HENDERSON, H.E.I.C.S.,

Spring Grove, Hounslow.

Persons about to Assure are invited to examine the peculiar features of his Society.

By the introduction of an important principle, provision has been made whereby a Policy-holder of three years' standing can continue his Policy even though he should be unable to pay the premium.

Loans granted on approved Securities combined with Life Assurance.

This Society remunerates Medical men for their Reports, and allows them Commissions upon all business they may influence direct to the Chief Office.

Prospectuses, Forms of Proposal, and every information may be obtained (post free) on application to the Secretary at the Chief Office, to whom applications for vacant Agencies may be addressed.

EDWIN H. GALSORTHY, Actuary.

JOHN CAZENOVE, Secretary.

## For Infants.—The British Feeding

BOTTLE (registered) may be placed in any position without the Food running out. The supply can be regulated by a stop-cock: being electrified, it may be instantaneously cleaned. Unlike wood, ivory, or bone, it is impervious to moisture, cannot crack or become sour; there is no possibility of the infant drawing air with the food.

By W. T. COOPER, Pharmaceutical Chemist, 26, Oxford-street, London. Price 7s. 6d., or free to any Railway Station, 8s. 6d.!

## Report of the Directors of the Clerical,

MEDICAL, and GENERAL LIFE ASSURANCE SOCIETY, presented at the Annual General Meeting, held at the Society's Office, No. 13, St. James's-square, London, Friday, November 27, 1857.

It will be in the recollection of the Proprietors, that, at Two Extraordinary General Meetings held on the 1st and 28th of January last, the period for holding the Annual Meetings was altered from March to November, in order that earlier publicity might be given to the state of the Society's affairs at the end of June, that being the period fixed by the Deed for the termination of each financial year. In consequence of this alteration no Meeting took place in March last, and it is therefore now the duty of the Directors to lay before this Meeting a statement of the transactions of the Society for the Two years ending June 30, 1857.

The number of New Policies issued within that period was £1097;

The amount of Assurances granted was £305,300; and

The New Premiums arising therefrom amount to £20,729 per annum.

The Assurance Fund, notwithstanding the payment in cash of £65,384 as Bonus, since the declaration in January, has increased during the two years by no less a sum than £55,678.

From these facts it will be readily perceived, that during the period under notice, the progress of the Society has been in no degree retarded by the effects of the war, by the state of the money market, or by the active competition which has existed amongst kindred Institutions.

After the full and comprehensive statements made at the Extraordinary Meeting in January last, when the SIXTH BONUS was declared, the Directors feel that there is little further now to communicate; but they cannot refrain from mentioning that the Bonus then divided, which averaged 46 per cent. in Reversion, and 27 per cent. in Cash, on the Premiums received since 1851, has given general satisfaction, and has tended materially to sustain and advance the high estimation in which the Society has been so long held by the Public.

An Account of the Proceedings at the last BONUS MEETING, setting forth the Assets and Liabilities of the Society, and also the FAVOURABLE POSITION IN WHICH PERSONS WHO NOW ASSURE will be placed, can be obtained on application.

GEORGE H. PINCKARD, Actuary.

GEORGE CUTCLIFFE, Assistant Actuary.

13, St. James's-square, London, S.W.

N.B.—A Fee of ONE GUINEA is paid to the MEDICAL ATTENDANTS of all Persons proposing to Assure.

## Metropolitan Life Assurance Society,

No. 3, PRINCES-STREET, BANK, E.C.

FOR  
MUTUAL ASSURANCE.

DIRECTORS.

Daniel Burges, jun., Esq., Bristol.	Sir Benjamin Hawes, K.C.B.
Thos. A. Bushby, Esq., Liverpool.	John Laurence, Esq.
Peter Cator, Esq.	William J. Leacher, Esq.
James Dawson, Esq.	James Lloyd, Esq., Birmingham.
Francis Fox, Esq.	George Pearce, Esq.
Richard Fry, Esq.	Joseph Pease, Esq., Dartington.
Robert Grant, Esq.	J. Ingram Travers, Esq.
Wm. Grant, Esq., Portsmouth.	Joseph Underwood, Esq.
George Harcourt, Esq.	George Vaughan, Esq.

EX-DIRECTORS (by rotation).

Frazer B. Honshaw, Esq.

Henry Sturt, Esq.

Sir Joseph Paxton, M.P., Chatsworth.

PHYSICIAN—Dr. Fox, No. 30, New Broad-street.

SURGEON—John Hilton, Esq., F.R.S., No. 10, New Broad-street.

SOLICITORS—Messrs. Amory, Travers, and Smith, No. 25, Throgmorton-street.

The Directors hereby give notice to members whose Premiums fall due on the 5th of January next, that the same must be paid within 30 days from that date.

The Premiums are paid yearly, half-yearly, or quarterly, on the 5th of January, 5th of April, 5th of July, and 5th of October, either of which several days constitutes the commencement of the year to members. Persons, therefore, desirous of entering the Society as members on the 5th of January next, should appear or lodge their proposals at the office on or before that day.

This Society, for mutual and general assurance, appropriates the whole of its profits to the benefit of parties assuring their own lives for the whole term of life as members of the Society.

For the year ending 5th of April, 1858, an abatement of 51 per cent. has been declared on the premiums of all members of five years' standing and upwards.

The accumulated capital of the Society exceeds £800,000.

The annual premiums on existing policies are upwards of £100,000.

HENRY MARSHAL, Actuary.

Princes-street, Bank, E.C., Dec. 1, 1857.

## Williams and Son's Pure Glycerine

SOAP. Analysed by Dr. Hofmann, F.R.S., and Professor Redwood, Ph.D., strongly recommended by many eminent members of the Medical Profession, and favourably noticed by the following Medical Journals:—

THE LANCET.  
THE MEDICAL TIMES AND GAZETTE.  
THE BRITISH MEDICAL JOURNAL.  
THE MEDICAL CIRCULAR.  
EDINBURGH MEDICAL JOURNAL.  
THE DUBLIN HOSPITAL GAZETTE.

It is suited to all cases of delicate skin (whether arising from disease or otherwise), and is admirably adapted for nursery use. May be had of all respectable Chemists, Perfumers, &c.

SOAP-WORKS, CLERKENWELL, LONDON, E.C.

**Broughams.—Kinder, M'Naught, and SMITH, MANUFACTURERS, WORCESTER,** beg respectfully to invite the attention of professional men to their improved Medical Broughams, as under:—

Width of Seat,	Weight,	Price.
8 ft. 6 in.	7½ cwt.	85 Guineas.
8 ft. 6 in.	8½ cwt.	95 Guineas.
8 ft. 7 in.	9 cwt.	100 Guineas.

The latter, including a segmental front, with seat for third person. These Carriages are constructed, by the aid of machinery, of the best material, are of excellent workmanship, and particularly adapted to the wants of medical men, either in town or country. Drawings and other particulars forwarded on application.

## Society of Arts' Prize Achromatic

**MICROSCOPE, at £3 3s.**—C. DAKER, of 243 and 244, High Holborn begs to inform the Profession that he is now enabled to offer the **PATTERN MICROSCOPE**, so much esteemed by the Society of Arts, finished in a superior manner, with three Powers and Apparatus, in Mahogany Case, for £3 3s. They are particularly useful for Students, as every Physiological examination can be made with the same result as is obtained with the more expensive kind. Catalogues by post, free. Every description of Instrument taken in exchange. Established 1765.

## Water Beds for Invalids, free from

smell, (for Water at any Temperature,) £23 to £5 10s. Water Cushions, from 17s. 6d. Waterproof Bed Sheets. Urinals and other Surgical Appliances. Water Beds on Hire, 7s. per Week. **THOMAS WATTS AND CO., INDIA-RUBBER MANUFACTURERS, 406, OXFORD-STREET, LONDON, W.C.**

**Dr. Arnott's**  
FLOATING  
WATER BEDS, the New Elastic Hot and Cold Water Beds and Cushions, the Adjusting Bed. All kinds of Hospital and Invalid Appliances, Waterproof Sheetings, etc. Beds let

on hire. Prices and particulars furnished on application.  
EDWARD SPENCER and Co., 18, Billiter-street, London, E.C.

## Nervous and Mental Disorders.—Wyke

House, Slon Hill, Isleworth, Middlesex, a private establishment for the care and recovery of Ladies and Gentlemen mentally afflicted. Conducted by Mr. ROBERT GARDINER HILL, late Resident Medical Proprietor of Eastgate House, Lincoln, and by Dr. E. S. WILLETT.

**Dissecting and Post-MORTEM INSTRUMENTS, New and Second-hand, of the very best quality, at**

**PRATT'S,**  
SURGICAL INSTRUMENT MAKER,  
Inventor of the New Bullet and Lithotomy Forceps, with Rule and Sheath, also of a New Truss for Hernia, all which have been approved and ordered by H.M. Army Medical Board,  
420, OXFORD STREET,  
20 doors from Tottenham Court-road.

Elastic Stockings, Wooden Legs, Crutches Bandages and Trusses,  
WHOLESALE AND RETAIL.

## Recent Improvement by Mr. Jeffreys

in the **RESPIRATOR**. J. E. PERCIVAL respectfully invites the attention of the Profession to an important improvement in the Oral Respirator, which, having a maximum warming power of no less than 40°, can be instantaneously reduced, even without being displaced, to any of five grades down to a minimum of about 15°, and vice versa. So that, in an atmosphere varying between 30° and 55°, air may be respired of one steady temperature of about 70°, or lower if desired.

The Profession are doubtless aware that the name Respirator is being assumed for various defective imitations. The **RESPIRATOR** may be had of the principal Chemists and Surgical Instrument Makers in town and country. Wholesale Office, 25, Bucklersbury, City. J. E. Percival, Manager.

## Horniman's Pure Tea, the leaf

not coloured.—Rich full-flavoured **TEA**, of rare strength, is thus secured, as importing it not covered with colour prevents the Chinese passing off the brown flavoured Autumn Crop as the best. The "Lancet Report" (Longmans, p. 318) states of H. & Co.'s Teas:—"The Green not being covered with Prussian Blue, &c. is a dull olive; the Black is not intensely dark;" wholesomeness is thus secured, and the consumer benefited. Price 3s. 8d., 4s., and 4s. 4d. per lb. Sold by Elphinstone, 227, Regent-street; Fursell, 78, Cornhill; Dodson, 98, Blackman-street, Borough; and in all parts of the Kingdom by Agents.

TO SURGEONS, APOTHECARIES, AND DRUGGISTS.

## Important Saving, by Prepayment

in the PURCHASE of  
**NEW WHITE ROUND MOULDED VIALS OF THE BEST QUALITY.**  
PELLATT and Co. submit the following PRICES of VIALS, for PRE-PAYMENT only:—

Quantity	Price per Gross, 6s.	In quantities of not less than
14 dr., and 2 oz.	7s.	Six Gross, assorted to suit the convenience of the purchaser, delivered to carriers in London. No charge for Package. Breakage at risk of Purchaser.
8 oz.	8s.	
4 oz.	10s.	
6 oz.	15s.	
8 oz.	18s.	
4½ oz. graduated in 8 doses,	12s. 6d.	

The above Prices being based upon a calculation which excludes all charges whatever between the Manufacturer and the Consumer, no attention can be paid to any order not accompanied by a remittance in full made payable in London.—P. and Co. do not supply Green Glass.—Orders and remittances to be addressed,

PELLATT & Co.,  
FALCON GLASS WORKS, LONDON.

## Wines from Cape of Good Hope.—

**PORT, SHERRY, MARSALA, MADEIRA, BUELLAS, &c.**, all at 20s. per Dozen—pure and wholesome Wines, free from acidity and Brandy, the produce of vineyards at the Cape of Good Hope, where the vines of Portugal and Spain are now being carefully cultivated, and have escaped the disease. Her Majesty's Government allows these Wines to be imported at half the duty, hence the low price of 20s. per dozen. Samples of any two qualities sent on receipt of twelve stamps.

"That wine, equal to any ever produced, can be made at the Cape, all the world has acknowledged."—Times, Nov. 8th, 1856.

The **UNIVERSAL BRANDY**, 15s. per Gallon, or 30s. per dozen.

W. and A. GILBEY, Wine Importers, Brandy Distillers, &c., 372, Oxford-street, London, W. Cheques to be crossed to our Bankers, the Bank of England.

## Crosse and Blackwell, Purveyors in

Ordinary to Her Majesty, respectfully invite attention to their **PICKLES, Sauces, Tart Fruits**, and other table delicacies, the whole of which are prepared with the most scrupulous attention to wholesomeness and purity. The practice of colouring pickles and tart-fruits by artificial means has been discontinued, and the whole of their manufactures are so prepared that they are not allowed to come in contact with any deleterious ingredient. A few of the articles most highly recommended are, Pickles and Tart Fruits of every description, Royal Table Sauce, Essence of Shrimps, Soho Sauce, Essence of Anchovies, Jams, Jellies, Orange Marmalade, Anchovy and Bloaters Pastes, Strasbourg and other Potted Meats, and Cal's Foot Jellies of various kinds for table use. C. and B. are also sole agents for M. Soyev's Sauces, Relish, and Aromatic Mustard; and for Carstairs' Sir Robert Peel's Sauce, and Payne's Royal Osborne Sauce. The above may be obtained of most respectable Sauce Vendors throughout the United Kingdom; and Wholesale of

CROSSE and BLACKWELL, 21, Soho-square.

## Great Reduction in the Prices of New

**MEDICAL GLASS BOTTLES and PHIALS, at the ISLINGTON GLASS BOTTLE WORKS, ISLINGTON-PLACE, PARK-ROAD.**  
Warehouse—2, UPPER COPENHAGEN-STREET, BARNSBURY-ROAD, ISLINGTON, LONDON, N.

E. and H. HARRIS beg to submit the following prices for quantities of not less than 6 gross, assorted to suit the convenience of the purchaser.

6 & 8 oz., any shape, plain or graduated ..	8s. per gross.
3 & 4 oz., do. ..	7s. 6d. do.
1 oz. white moulded phials ..	4s. 6d. do.
1 oz. do. ..	5s. 6d. do.
1½ oz. do. ..	6s. do.
2 oz. do. ..	7s. do.

No remittance required until the goods are received. Packages free. Delivered free within 7 miles. Immediate attention to country orders. Post-office orders, made payable to E. and H. HARRIS, at the Chief Office, London.

Bankers: Union Bank of London.

## Hypophosphites of Lime and Soda,

as used by Dr. FRANCIS CHURCHILL, of Paris, in the Treatment of Phthisis (vide Medical Times and Gazette, August 1st, 1857,) may be obtained from the Manufacturers.

Ferrins and Barnitt have likewise prepared a series of the Hypophosphites, including the Potassa, Ammonia, Baryta, Strontia, and Iron Salts for those of the Profession who may wish to test their therapeutic value.

In order to secure the use of pure Hypophosphites they would suggest the necessity of observing the fac-simile of their signature over the stopper of each bottle; this is the more necessary, as samples that have been forwarded to them for examination proved very impure.

PERRINS and BARNITT, Operative Chemists, 22, Conduit street, London, W.

## ORIGINAL LECTURES.

## LECTURES

ON

THE ANATOMY, INJURIES, AND DISEASES  
OF THE HEAD,

DELIVERED IN THE

Theatre of the Royal College of Surgeons of England.

By PRESCOTT HEWETT,

Professor of Anatomy and Surgery to the College.

## ON FRACTURES OF THE SKULL.

## LECTURE I.

IN these lectures it is my intention to divide the subject of fractures of the skull into two parts. 1st. Fractures of the vault; and, 2ndly, fractures of the base of the skull.

To such a subdivision some objections may, doubtless, be raised. It may be urged that some of the bones belong both to the vault and to the base; and, moreover, that all the bones of the skull are so intimately locked together, that, as a natural consequence, fractures of one of these regions frequently spread into the other region. But then, on the other hand, it may be said that some forms of fracture are, in many cases, and especially about the vault, altogether confined to the original seat of the injury, and that all questions of operative interference are, and must be, almost invariably limited to injuries of the upper and lateral parts of the skull. And these are, I think, good and sufficient grounds, in a practical point of view, for making the subdivision which I propose.

In the vault of the skull most of the fractures are direct; the bone, in fact, gives way at the spot where the blow was struck. The result of this giving way of the bone may, according to the nature of the accident, either be a simple splitting of the osseous tissue, or the bone may be broken into fragments of various sizes and shapes.

Produced generally by a diffused blow, the simple splitting, or crack-like fissure is most frequently not limited to the original seat of the injury; this is a most important point, and it will be well for us to bear in mind that, branching far and wide, this kind of fracture very commonly passes from the vault into the base.

The comminuted fracture, on the other hand, resulting from a more or less concentrated blow, is not so apt to spread from the original seat of the injury; one or more bones may, it is true, be smashed, but most commonly the injury is far less extensive.

In these comminuted fractures, the fragments may either still retain their proper level, or they may be displaced and driven inwards; but let us recollect, that in this in-driving of the fragments either one of the tables alone may be involved, or, as is much more commonly the case, the whole thickness of the bone.

The external table alone may, it is well known, be thus broken, and driven down in any part of the vault, and especially may this be the case in the parts corresponding to the frontal sinuses and mastoid cells, where extensive depressions often occur without any injury of the inner table.

And accurate observations teach us that the internal table alone may also be broken and depressed without any injury of the outer table. Such fractures are, it is true, very rare, but however rare, there is now no doubt as to their existence. But, if such cases are rare, instances of splintering and depression of the inner table, with some degree of injury of the outer plate, unaccompanied by depression, are not uncommonly met with.

In the vault of a skull belonging to the Museum of St. George's Hospital, is a well-marked instance of very extensive splintering and depression of the inner table, without any injury of a corresponding nature on the outer part. And there is also another well-marked specimen of the variety of this form of injury, which has been so much dwelt upon by the late Mr. Guthrie. A simple clean cut, of an inch long, through the outer layers of the bone, with splintering and depression of the inner plate alone.

In such instances it sometimes happens that a single frag-

ment of the inner table is detached, and lies loose on the dura mater; but it much more frequently happens, as in the specimen to which I have just alluded, that the fragments, driven down at the centre, still remain more or less connected by their circumference to the neighbouring parts of the bone.

Mr. Guthrie's remarks on this important subject chiefly relate to sabre-cuts; but such appearances about fractures of the skull are by no means uncommon in our Civil Hospitals. A fracture of this kind may happen when a smart blow is inflicted on the skull by a more or less pointed instrument, or by the corner of a brick, or angle of a tile. M. Denonvilliers showed a specimen of this kind to the Société de Chirurgie de Paris, in which the injury had been produced by a slate falling on the head. A case is also described by Mr. Benjamin Philipps, (a) in which a large fragment, about two inches and a half long, was found completely detached from the skull-cap, and sticking in the dura mater; in the outer table was a clean cut, made by a flat iron or shovel. Another case occurred in the practice of Samuel Cooper, the accident being caused by a nail projecting from a door which had fallen on the patient. In the specimen which I have just shown you, the boy had fallen out of a cart, and no doubt the bone was cut by some sharp stone lying in the road, along which he had been dragged.

In all these cases the inner table was much more extensively broken than the outer one; and so it is in all ordinary cases of fracture with depression.

The appearance just referred to, that is, the splintering and depression of the inner plate, is usually attributed to its greater density, and consequent brittleness. There is no doubt, however, that the direction in which the force acts tends in some measure to produce these effects; and if we observe them so much more generally about the inner than the outer parts of the skull, it is that the force generally acts from without inwards. But let the force act in the opposite direction, and then the common order of appearances becomes reversed; we shall, in fact, find that the outer table is now more extensively splintered than the inner one. Of this Mr. Erichsen mentions a well-marked example. A man committed suicide by firing a pistol into his mouth. The ball, passing through the vault of the skull, struck the inner plate, and then the outer one; the latter was much more extensively splintered than the former. The same fact is shown in some other specimens in the different museums of our London Hospitals.

Fractures with displacement present some varieties deserving of notice. There may be, as in a specimen in the museum of St. George's Hospital, a single line of fracture extending some distance, with a great and an extensive over-riding of one side of the fracture. This, however, is not a common form of injury. But a very common form of fracture with depression is that in which an oval piece of bone is driven down, the broken piece being more or less split longitudinally, with its centre much more depressed than the circumference, so that the fragments slant towards each other. Such a fracture, presenting externally but two fragments, may have a tolerably smooth surface; but internally, the plate is broken into several fragments, with large, projecting, and irregular points, several of which may wound the dura mater. A specimen in St. George's Hospital museum affords a strongly marked instance of this form of fracture, which I have repeatedly met with in various parts of the vault. The accident is most commonly produced by some heavy body with a sharp margin applied with great force, such, for instance, as a quoit or a horse's shoe. In the numerous instances which I have met with, this form of fracture did not spread beyond the point which was struck. Let me not, however, be understood to say that it never does so. But perhaps the most ordinary form of fracture with depression is that in which several fragments, more or less of a triangular shape, have their points extensively driven down, and firmly wedged into each other, whilst their bases still remain on a level with the neighbouring bone. Taken as a whole, the broken portion is here, too, almost always of an oval shape, and cracks and fissures involving only the outer table are frequently found disposed around the depressed piece. And here, too, whatever be the extent of the injury in the outer part of the bone, that on the inner side is more extensive still.

It will be of use for us to recollect that fractures with depression, when produced by a heavy blow acting on a large

(a) Med. Gaz. vol. xxxiii. 1844, p. 129.

surface, are oftentimes accompanied by fissures extending in various directions, and reaching to distant parts of the skull, even into the base not unfrequently.

Can a depression take place without a fracture? In young children, when the bones are still pliant, such an accident might possibly occur; but even here, in a well-marked depression, some of the bony fibres give way, so that the case cannot, in truth, be likened to an indentation of a metal. Such being the case in early childhood, what is to be thought of those instances of this form of injury which are reported to have occurred in adult life? Why that, doubtless, from some accidental cause, the nature of which was not sufficiently taken into account, such reports are founded on error. If such an accident could possibly occur, it ought, by this time, to have been clearly demonstrated by some preparation or other; and, until such a preparation be brought forward, the existence of this form of injury ought certainly not to be admitted.

A wound of the integument leading down to the bone may accompany every variety of fracture of the vault. And let us ever bear in mind that in these compound fractures the breaking of the bone is very much more frequently strictly confined to the seat of the injury than it is in cases of simple fracture. Thus, in examining twenty cases of compound fracture of the vault, I found that the injury to the bones was thus strictly limited to the original seat of the blow in eight cases, whereas in fifty-six cases of simple fracture, this strict limitation existed only in one single instance. It was not that the injury in the compound fractures was caused by sharp instruments; such instruments were the cause of the injury in two cases only; in the other six it followed heavy blows, either from falls or from blunt instruments. In the single case of simple fracture in which the fracture was limited, the patient having fallen off his coach-box, had struck his head against the ground.

And here let me, for one moment, call your attention to the two cases where the fracture was caused by sharp instruments, as the appearances observed in these cases were somewhat peculiar. A piece involving the whole thickness of the skull having been detached on three sides, was bent upwards, and thus raised two or three lines above the level of the skull; the fragment was, however, immovable, as it was still connected at one side to the surrounding bone, the external table of which was at this part only partially fractured—in fact, the appearances may be said to have resembled a box with its lid open. In one instance the injury had been produced by a chisel falling from a great height on the head; in the other, the patient having fallen from a great height with his head upon some iron railings, one of the spikes had penetrated through the bones. And well do I recollect that in both instances, the surrounding parts being extensively infiltrated with blood, the appearances which I have just described were by several mistaken for fractures with depression.

All the varieties of fracture of the vault which I have thus far described are those commonly seen in our civil hospitals; but in military practice fractures of a very different kind are most frequently met with in this region. I allude to that form of fracture produced by horizontal sword-cuts, in which large pieces of bone are often sliced off. In such cases as these, as the instrument is generally a sharp one, and the blow well dealt, the injury is strictly limited to the spot which was struck; there are none of those extensive fissures so commonly met with in our civil hospitals, and this it is which gives such a peculiar feature to fractures of the vault in military surgery. Look into the various Museums in London, and you will there find many specimens of extensive sword-cuts slicing off large pieces of bone, after which the patients lived some time, the fracture being more or less well healed; but how few preparations, comparatively speaking, of extensive fractures of the vault healed will you find from our civil hospitals!

Are there any signs by which we can in all cases recognise the existence of a fracture of the vault? No. Daily experience teaches us that the signs, so much dwelt upon even by our immediate predecessors, are not of the slightest value. In the dead-houses of our Metropolitan Hospitals, fissures involving the whole of the vault of the skull are to be constantly seen, the existence of which was never even suspected during life. Even an extensive and a comminuted fracture, with great depression of the fragments, may, and often does, escape notice, when the broken bone lies hidden under the temporal muscle, or when a large extravasation of blood masks the state of the parts below. On the other hand, these extravasations

of blood sometimes so strongly resemble fractures with depression, that errors in diagnosis may very easily be committed. Of this you will recollect that I brought forward, in the preceding lecture, several examples in which Surgeons of the greatest experience had thus been misled. Again, we may chance upon a case with an abnormal condition of the skull in which extensive depression exists. You will find several such cases described as congenital malformations. Platner, for example, mentions the case of a man who, having a large congenital depression of the bones of the vault, narrowly escaped being trepanned, after a fall from a great height, which had rendered him perfectly insensible for some time. Such depressions of the skull are not very uncommon. A gentleman who has been attending these lectures has since called my attention to two extensive depressions of the skull, which have been there ever since the time of his birth. And then the fact, now well known, of depressions being produced in the skulls of elderly persons by the absorption of the diploë, and thinning of the tables, is well worthy of being borne in mind.

Accompanied, however, by a wound leading down to the bone, fractures of the vault are, in general, easy of detection. But, even here, where we have all the advantages of being able by sight and by touch accurately to examine the bone, we are liable at times to be led into error by the appearances which we find. Many examples are on record where sutures or vascular grooves have been mistaken for fissures, and where, in by-gone days, the patient narrowly escaped perforation of the skull. In some of these cases, no doubt, the error arose from the carelessness of the Surgeon; but, in other instances, an abnormal disposition of a suture has misled even the most attentive. Let us recollect also that in compound fractures with depression, the condition, whatever that may be, of the outer plate of the bone is not always a guide as to the exact condition of its inner plate. Recal to mind, for instance, the extensive splintering of the inner plate, which exists in some forms of fracture, without any corresponding injury on the outer parts; and the depression of the outer plate without any injury of the inner one, especially about the frontal sinuses. There is, however, one sign indicative of fracture of the skull, about which one would have thought that there could not possibly have occurred any mistake. I allude to the escape of cerebral matter. But even here, strange to say, *Maréchal* (a) mentions a case in which the inspissated secretion of the frontal sinuses was mistaken for brain-substance thought to be oozing out of a fracture in this region.

There is also on record a singular instance of the appearances which may lead to an error in diagnosis as to a compound fracture of the skull.

A woman was admitted into the *Hôtel Dieu*, with a wound in the temporal region, accompanied by much bleeding. A fragment of bone, several lines in length, was found deep in the wound, and quite loose; this was removed, and the finger then passed through an opening, the circumference of which was unyielding. The case was at once thought to be one of compound fracture of the skull, with separation of some fragments. But it was soon remarked by a by-stander that the fragment of bone which had been removed was dry, and quite white, as if it had been macerated. This led to a more careful examination of the wound, and it was discovered that the supposed hole in the skull was nothing but a laceration of the temporal fascia, and the fragment, the innocent cause of the error, turned out to be simply a piece of bone which, lying on the ground, had been driven into the temple when the patient fell. (b)

I proceed now to the treatment of fractures of the vault of the skull, a subject in which are involved, even in the present day, as we shall find, some of the nicest and most litigated points in the practice of surgery.

Every variety of fracture of the vault of the skull may, it is well known, exist without symptoms: the bone may be battered in—the brain protrude, and all this without a single symptom. On the other hand, every variety of fracture, even the narrowest fissure, may lead to mischief of a deadly nature; and the symptoms denoting this mischief may appear at once, that is, upon the receipt of the injury, or some time afterwards. The primary symptoms depend upon compression, caused either by an extravasation of blood, or by de-

(a) *Mém. de l'Acad. de Chir.* vol. i. p. 247.

(b) *Denonvilliers. Thèse de l'Applicat. du Trépan sur les Os du Crane*, p. 16.

pression of bone. The secondary symptoms are connected with irritation or inflammation of the parts within the cranium, and here again we may have compression of the brain, from inflammatory effusions.

Already have we examined, in one of the preceding lectures, all that belongs to extravasation of blood; now, therefore, we have to deal only with the mischief already produced by, or likely to arise from, the fracture itself.

And, first, as to lineary fracture or fissure. Clear, indeed, and universally recognised, in the present day, are the principles by which we are to be guided in this case. A simple fissure, unaccompanied by symptoms, passes altogether unnoticed. If there be a wound, by which alone we can recognise the existence of the fissure, that wound we are to treat as we should any simple scalp-wound. And, should any symptoms arise subsequently, we must act according to circumstances.

Now and then, we find these cases of fissure of the skull, either simple or compound, following exactly the same course as those of scalp-wound and confusion of the bone which I brought before your notice some time back. The injury gives rise to suppuration between the bone and the dura mater, and then follows the train of symptoms I dwelt upon at some length.

(To be continued.)

## ORIGINAL COMMUNICATIONS.

### ON THE SUBCUTANEOUS DIVISION OF THE TENDO-ACHILLIS,

AND THE PROCESS OF REPAIR.

By HOLMES COOTE, F.R.C.S.

Assistant Surgeon to St. Bartholomew's and to the Royal Orthopædic Hospital, &c.

I have lately had the opportunity, through the kindness of my colleague Mr. Tamplin, of examining two specimens of subcutaneously divided tendo-achillis, taken from the same subject, the one operated on three months, the other rather less than two months, before the death of the patient.

**Case 1.**—An undersized man, æt. 38, suffering from lateral curvature of the spine and talipes equinus of both limbs, a cripple, unable to put his feet to the ground, was admitted in the month of August, 1857, into the Royal Orthopædic Hospital under Mr. Tamplin. The right tendo-achillis was divided August 27; the left, Sept. 30. Scarpa's shoe was applied to both feet, and the heels were well brought down by the end of the present month (November). On the 23rd Nov., the influenza being then prevalent, he was seized with cough and cold. Pneumonia of both lungs rapidly ensued; he lay restlessly upon the right side until the 26th, when he rapidly sunk, and expired about 6 in the afternoon.

The examination of the body, which was performed by Mr. Pocklington, detected consolidation of the right lung, and a great amount of secretion in the bronchial and pulmonary tubes of the left. With these post mortem appearances, however, I do not wish to interfere. The divided tendons, with the newly formed connecting tissues, were removed, and to these attention was particularly directed, inasmuch as no instance is, I believe, at present on record of the examination of such parts, as seen in the adult, two or three months after operation.

The right tendo-achillis was adherent to its sheath.

It presented the usual pearly white colour. The surrounding vessels, especially the veins, were full and tortuous. The external fibrous investment was complete and of usual appearance; but between the two extremities of the tendon there was a compressed portion two inches in length, the transverse measure of which, as compared to the obviously normal part, was as two-eighths to three-eighths of an inch. A longitudinal incision through the tendon showed an interval of just two inches between the divided ends of the normal tendo-achillis, which were united by a light grey semi-transparent structure, through which were traced well-formed opaque pearly white fibres, passing from one extremity to the other of the cut tendon. The new tissue was clearly defined

from the old, being of a totally different colour, the opaque white hue of the normal structure standing out in strongly marked relief. After drying for a short time the new tissue acquired a rosy tint, obviously due to the blood contained in numerous capillaries.

The interval between the cut extremities of the left tendon did not exceed one and a half inch. The transverse measurement was the same as in the preceding specimen; but along the sheath there were numerous patches of extravasated blood. The opaque white fibres of the original tendon were separated in parts at their junction with the newly formed tissue, which appeared in the interspaces, and were dovetailed. Towards the lower end of the connecting medium, near its junction with the calcaneal portion of the tendo-achillis, there was an oval cyst half an inch in length, containing dark fluid blood.

The examination of the newly formed tissue under the microscope exhibited some points of interest. It contained a large proportion of oil globules intimately mingled with the firmer and more fibrous material. The latter consisted of granular matter, and of newly formed fibres of ill-defined contour; yet exhibiting in many situations the appearance of being formed of elongated nuclei, for at the broken edge of the specimen numerous loose nuclei were seen floating about free, or united in linear series of three or more. There were some whiter and more opaque parts among the newly formed tissues; these closely resembled, but did not quite equal in clearness or in contour, the normal white fibrous tissue of histologists.

The specimens here described are interesting as contrasted with others, of equal value, presented by Mr. Tamplin to the museum of the Royal College of Surgeons. These were the tendo-achillis, and the tendons of the tibialis posticus and anticus muscles of a child nine months old, in whom, at the age of five months, these tendons had been divided for congenital varus. The child had perfect use of its feet before death, and when it died, no trace of an operation could be detected even by microscopical examination.

The question here suggests itself, Does the absence of abnormal appearances in the tendons of the infant arise from the gradual conversion of the connecting medium into white fibrous tissue? or does the connecting tissue contract so as ultimately to approximate the ends of the divided tendon, and form a "linear cicatrix"?

I must confess that in the specimens before me there is the very faintest approximation of normal appearances in the connecting tissue. The divided ends of the tendo-achillis seem imbedded in a soft pulpy mass of quite different consistence and colour. The absorption of the oily and soft material would have reduced this structure to at least one-third its present bulk; and it would have acquired the appearance of a narrow cord. I am not, therefore, prepared to acknowledge that the newly formed tissue gradually acquires so much of the properties and of the external characters of tendon as to be with difficulty distinguishable. On the contrary, it would rather seem that a slow process of approximation is effected between the cut ends, and that this is combined with an altered sphere of muscular action.

It may be urged in opposition to this view, that the interval between the cut extremities of the first divided, and consequently more completely repaired tendon, was longer than that of the opposite. It must be remembered, however, that no great length of time had elapsed since the operation—scarcely three months; and that in all probability twelve months would be required for the completion of all the processes of repair in an adult.

The cyst of blood at the lower extremity of the connecting tissue in the left leg, due to some slight excess of the extending force, shows the necessity of proceeding with care in the re-adjustment of the distorted parts. One of the principal laws in the practice of Orthopædic Surgery is to proceed slowly, that tissues may yield and not tear. The specimens here quoted illustrate the importance of the remark.

I should conclude that when specimens are examined in which no trace of the division of the tendon can be found, the divided ends have become approximated so as to constitute a close linear cicatrix. But that when the connecting tissue has been elongated it always preserves some of its distinctive characters, either as regards its bulk or its minute structure. "I am of opinion," observes Mr. Tamplin in his work on Deformities, "that the new substance will and does admit of

sufficient extension to compensate for the greatest amount of shortening met with in any deformity; for I have repeatedly, in cases of talipes equinus, found the new connecting medium full two inches in length, within three or four weeks following the operation, especially in those cases where there is no resistance in the joint, and where the foot admits of being rapidly brought into its normal position."

## ON DISLOCATION OF THE CRYSTALLINE LENS.

By W. WHITE COOPER, F.R.C.S.  
Ophthalmic Surgeon to St. Mary's Hospital, &c.

(Continued from page 7.)

It has been remarked that displacement downwards, as the immediate effect of a blow, occasionally occurs. I am not now referring to the simple dislocation of the lens into the anterior chamber, but to the more formidable bursting of the eye from a blow, the lens being driven down, whilst the rupture is above. A case of this kind is now under my observation.

*Partial dislocation downwards of lens.*—In December, 1856, Apps, an umbrella-maker, was struck violently on the left eye with a shoemaker's hammer. His face was rather turned from the man, so that the force of the blow fell partly on the eye and partly on the lower edge of the orbit near the nose, where a wound was inflicted. Such was the force of the blow, and such its effects, that the poor fellow remained nearly unconscious for a week, and is said to have lost a considerable quantity of blood at the time of the injury. He was laid up, unable to work for eight months, suffering great pain over the brow and head.

When I examined him on the 8th November, the condition was as follows:—The globe tense, and somewhat conoidal; the upper and outer third of the sclerotic discoloured, inclined to be staphylomatous, and there is the mark of a

cicatrix just at the margin of the cornea. The cornea is somewhat projecting; of the iris merely a narrow strip remains, and this is wanting at the upper and the outer part; the lens is luxated, and tilted downwards and forwards, the lower edge pressing the iris against the inferior border of the cornea.

The lens is somewhat flattened, doubtless by absorption, the margin is semi-transparent, the nucleus is

opaque. Sight is entirely extinct in that eye, and impaired in the right eye to such an extent as to prevent his following his work.

This appeared to me a proper case for excision of the globe to preserve the other eye from blindness. The patient withheld his consent for a time, but finding his right eye become more dim, and suffering from neuralgia of the left brow and temple, he yielded, and the operation was performed at St. Mary's, on the 9th December. The canthus was not divided, but the globe was removed with great facility, the tendon of each muscle being taken up with a strabismus hook and cut through, then passing my fingers into the orbit I drew the globe forward, and with a couple of strokes of curved scissors the separation was completed. Not an ounce of blood was lost, and the patient recovered rapidly, an artificial eye being inserted on the ninth day after the operation.

Fifteen minutes after removal, the eye was examined by my colleagues, Dr. Sieveking, Dr. Handfield Jones, and myself. The outline was altered, there being a staphylomatous fulness at the upper portion. The globe generally was dark brown, from thinning of the sclerotic: there was indication of a cicatrix near the upper and outer margin of the cornea, and some old extravasated blood still lay under the conjunctiva.

On cutting through the globe transversely, the vitreous humour was found to be perfectly fluid; the retina as nearly as possible transparent, no yellow spot discernible. Choroid very pale, and general absence of pigment; under the micro-

scope, particles like disorganised blood corpuscles were scattered over the external surface of the cornea.

The lens lay between the iris and the ciliary processes, which completely encircled it posteriorly. At the upper part, corresponding with the cicatrix, was a pouch-like appearance of these processes, as if a rupture had taken place.

The question had presented itself to my mind, whether removal of the luxated lens would be the proper step, but I decided in favour of excision of the eye, from the conviction that that alone would fully answer the object of saving the right eye. The thorough disorganization of the vitreous humour and the peculiar nipping of the lens between the iris and ciliary processes, to which it appeared to be firmly attached, rendering its removal extremely difficult and at the risk of emptying the globe, confirmed me in my decision.

Simple dislocation of the lens into the anterior chamber is far from uncommon. A sudden, unexpected blow is generally the cause, and the displaced lens having burst its capsule, speedily loses transparency. It is unnecessary to narrate ordinary cases of this description, but I will give a short history of four which present points of interest.

*Dislocation of lens; absence of irritation.*—An Irishwoman presented herself among the out-patients at St. Mary's in 1855 for my advice, and the first glance discovered an opaque lens lying in the anterior chamber. Not doubting that her application had reference to this, I told her that an operation would be necessary for its removal; rather to my surprise, she intimated that it was by no means her wish to have the lens interfered with, as it had been in its present position two years (having been displaced during a little difficulty with her husband), but that there was a bladder on her eye which was painful, and for that she sought advice.

The precise condition of the eye was as follows:—There was slight congestion of the conjunctiva, none of the sclerotic; the anterior chamber was more than half-filled with an opaque lens, which concealed the pupil, and rendered the iris concave.

The iris itself was slightly altered in colour, but gave no indication of having been the seat of acute inflammation; on the cornea was a transparent vesicle the size of half a pea, which was exquisitely sensitive. On being punctured this collapsed, and the

eye immediately became easy. The patient was desired to use a solution of nitrate of silver, and at the expiration of a week the eye was well, so far as the vesicle was concerned. She assured me that all pain ceased in the eye a few days after the blow which blinded it, and even the prospect of regaining sight would not tempt her to submit to the removal of the lens.

*Opaque lens in the anterior chamber; absence of irritation.*—In October last I was consulted by Mr. B., a gentleman from the West of England, who gave the following history:—Twenty-two years ago he suddenly lost the sight of his left eye, and came to town for advice. Two of the leading authorities failed to discover any sufficient cause for his blindness, and he left much disappointed. Shortly afterwards he consulted Dr. Butter at Plymouth, who at once detected cataract. Nothing had been done to the eye, which he assured me had for two years borne the appearance it presented when I saw him. In the anterior chamber lay a yellowish-opaque body, apparently the nucleus of the lens, and around it there floated small flocculi detached from it. The iris was not altered in colour, nor the consistence of the globe diminished. There was no indication of inflammatory action past or present, and this gentleman assured me that though formerly he had had some pain, he had long been free from it. A portion of the pupil was clear, but there was no sight. He was exceedingly nervous and excitable, and had the strongest objection to any operation; palliative measures, therefore, could only be prescribed. (a)

When we reflect on the extreme irritation often caused by the presence of a small fragment of cataract thrown into the anterior chamber by the needle, it is surprising that so bulky a mass as the entire lens should remain in this novel position without lighting up acute inflammation; these cases are, how-

(a) I have since heard that this eye has become the seat of irritation.

ever, exceptional, the two following presenting the ordinary characteristics.

*Dislocation of lens; neuralgia.*—Jane Webb, a servant, applied at St. Mary's, February 10, 1857. Two days previously, while coughing violently, she felt something give way in her left eye, and at once lost the sight. As she entered the Out-patients' Room my notice was attracted by her peculiar gait. Her head was thrown far back, and her eyes were nearly closed. On examination of the affected eye, a large densely-opaque, yellowish-white lens lay in the anterior chamber, completely shutting up the pupil. The iris was slightly discoloured, and the iritic zone was becoming marked. The girl complained of intense frontal pain, extending over the side of the head, depriving her of rest at night; she could not bear the light, nor could she carry her head in any other position than that mentioned, without increase of pain.

I decided on removing the lens, and proposed chloroform, to which she objected; this rendered extraction extremely difficult, as the eye was powerfully thrown upwards and outwards: at length a section was made, the lens being divided by the knife; on making pressure, one portion escaped through the wound, the other retreated through the pupil and passed out of sight. The anterior chamber being thus freed, the eye was bound up, and so little irritation followed that the patient left the Hospital on the third day.

The patient protested she had never had any affection of the sight or of the eye before the fit of coughing, but I have grave doubts of the correctness of her statement, the globe being decidedly soft and the vitreous humour disorganized.

*Dislocation of lens of twelve weeks' duration.*—James Housego was admitted into St. Mary's Hospital, March 23, 1855. Twelve weeks prior to his admission some dirt dropped into his eye; he rubbed it violently, and the sight at once became very indistinct, without material pain. It remained in the same state for fourteen days, when inflammation set in and the eye became worse and worse; blisters were applied to the temple and lotions used, but as no relief was gained he applied to the Hospital. On the 24th I found the eye presenting every indication of long-continued acute inflammation. The conjunctiva injected and chemosed; sclerotic intensely inflamed; iris discoloured; the pupil was widely distended by the opaque lens, which projected through it, and partially filled the anterior chamber. There was no question as to the course to be pursued, and I at once proceeded to extract the lens: the patient being placed under chloroform, I made the lower section, and with the scoop of the curette easily removed the lens. The pupil however did not contract. The lids were closed with a strip of plaster and cold water dressing applied. The extraction of the lens at once relieved the suffering, and the patient rapidly recovered from the operation; the iris however did not recover its contractility, nor had the pupil regained its normal size or its activity two months after the patient had left the Hospital.

We have seen two forms in which the displaced lens presents itself, namely, with its transparency retained, and as an opaque cataract; there is yet a third condition in which it is found,—where osseous degeneration has been superadded to the simple opacity. When the lens continues clear, we may conclude, not only that its capsule retains its integrity, but that the conditions of nutritive supply are not seriously impaired. In the second class of cases, the attachments may be severed, or the supply may be so far interrupted as to give rise to the death and opacity of the lens. The third form, the ossified lens, always represents a long-standing condition of disease. The ossific change is slow, but for it to take place, it is necessary that the sources of supply should not be arrested otherwise the interchange of particles cannot take place; as in those beautiful specimens of fossilized wood from Antigua, where the ligneous molecules are slowly disintegrated and as slowly replaced by silex; so here, though in a less regular and perfect manner, the ossific material is laid down in place of the normal lens structure. That this may closely resemble the structure of true bone is proved by a specimen described and figured in the sixth volume of the *Transactions of the Pathological Society*.

We are indebted to Mr. France for the narration of an interesting case of true ossification of the lens, which presented itself under the form of dislocation. A groom, aged 44, had received a blow on his right eye twenty years before, and the sight was completely extinguished by the severe subsequent

inflammation. He met with no fresh violence; but on rising one morning, three or four months before his admission into Guy's Hospital, he observed for the first time a white substance in the eye, which continuing permanently, excited constant pain and inflammation of variable severity. On his admission, there was visible at the bottom of the anterior chamber, occupying about three-fourths of the cavity, an oblong light straw-coloured opaque body, separated by a space from the cornea, but in contact with the iris.

Mr Morgan extracted this on the 10th of May, 1847. The case did well; the wound healed, and the patient was speedily convalescent, though the eye was amaurotic.

On examination, the lens proved to be in chief part hard and calcareous, resisting compression between the finger and thumb, or puncture with a knife, and tinkling when shaken in a phial. On chemical examination, it was found to be composed of carbonate and phosphate of lime, three proportions, cemented by two proportions of animal matter.

The irritation caused by such a hard and heavy mass shaking in the anterior chamber may well be imagined.

An interesting case of osseous dislocated lens has been recorded by Dr. Stoeber, of Strasburg. A stone-cutter, aged 49, had lost the sight of his left eye in infancy, from some unknown cause; but in 1832 he accidentally received a blow upon that eye from a clod of earth. This was followed by violent inflammation which never disappeared, the eye remaining irritable and especially susceptible to atmospheric influences.

In May, 1838, he consulted Dr. Stoeber, who saw the opaque lens lying in the anterior chamber, and proceeded to remove it. This he found no easy matter; for in making the section the knife grated as it touched the lens, showing that it was ossified. A hook was then introduced, which slipped without seizing the body, which was adherent to the iris. With some further difficulty the lens was detached by means of a needle, and removed. It was found to be hard, and to give the sound of a piece of flint when dropped on a slab of marble; it was, in fact, thoroughly calcareous. The patient recovered in eight days.

A not less interesting case has been published by Dr. Robert Taylor, and a third occurred in the practice of Dr. Warlomont, of Brussels. There are others noted, but these possess especial interest.

A few words now remain to be said as to the treatment proper for cases of dislocated lens.

When an opaque lens lies in the anterior chamber, it can only be regarded in the light of a foreign body, and the safest course will be to extract it. Instances have been mentioned where little irritation has been caused, but these are exceptional, and it must be borne in mind that inflammation may be lighted up at any moment—the vibration of a railway, the shaking of horse exercise, or a multitude of other circumstances, may give rise to it. According to my experience the operation of extraction in such cases is attended with little risk, and by its performance the eye is relieved from a great and constantly impending peril. Undoubtedly the consent of the patient may be withheld, and then we can only adopt palliative measures if inflammation exists, or precautionary measures if the patient has the good fortune to escape it. If the patient be very young—and Mr. Walton mentions a case of dislocated lens in an infant of three months old—absorption may take place without the necessity for an operation.

In proceeding to extract opaque lenses, I give the preference to the lower section; this enables the lens to escape at once if free, or if adherent to the iris, the connexion can be separated with facility. We should remember, when dealing with a spontaneously displaced lens (especially if the lens be osseous), that the vitreous humour is almost certainly fluid, and that, therefore, the gentlest handling will be necessary. If the hard lens is behind the iris and attached to it, the pupil will probably be so rigid as to make it exceedingly difficult for the lens to pass through; under these circumstances it is far better to slit the margin of the pupil with a pair of scissors, and so to enlarge it, than to endeavour to force the lens out; for the vitreous humour will escape, though the lens will not, and so the globe may be emptied to a serious extent.

Though not an advocate for the use of chloroform in ordinary extractions, I consider it of the greatest value when dislocated and osseous lenses have to be removed. Adhesions may exist; the operation is then necessarily prolonged, and

requires extreme care and delicacy in its performance. Without chloroform the eye becomes restless and irritable, retreating from every touch, while the lids spasmodically close. The anæsthetic, then, is a great boon to the operator, and a still greater to the patient, sparing much suffering while under the Surgeon's hands, warding off secondary neuralgic pain and irritation, and thereby hastening convalescence.

19, Berkeley-square.

### THREE CASES OF PUERPERAL CONVULSIONS.

ONE OF THEM FATAL, AND POST-MORTEM OF THE SAME.

By WILLIAM DALE, Esq.

*Case 1.*—Ann Pearse, aged 42, a spare woman, but enormously swollen over the whole body from œdema. She supposed she had exceeded the full period of pregnancy by at least a fortnight. She complained of head-ache on the morning of May 28th, for which aperient medicine was given; and in the evening she was seized with convulsions. The "fits" came on every half-hour, and lasted three or four minutes. They were very severe. There was foaming at the mouth, and they were succeeded by stertorous breathing; but between some of them she was sensible, and could be made to answer questions. There were no labour-pains, and the os uteri was not at all dilated. Countenance injected and almost purple; head very hot; pulse 90 and moderately full.

*Treatment.*—One dozen leeches to the temples; the head covered with wet rags; purgative and stimulant enemata; but as these afforded no relief, at midnight I took thirty ounces of blood from the arm, and with apparent benefit, as she only had two fits afterwards.

*May 29.*—Comatose; cannot be roused. To have two grains of calomel laid on the tongue three times a-day. Continue enemata night and morning, and apply a large blister to the nape of the neck. About noon this day the child was expelled by an easy and natural labour. It was dead and discoloured, as if it had been beaten with a stick.

*30th.*—Coma not quite so intense as yesterday. Continue remedia omnia. Shave the head, and apply linimentum hydragryi twice a-day.

After the above date, the patient gradually recovered her consciousness; but the powers of the mind were much impaired, and there supervened a state very similar to puerperal mania, which continued a week or ten days, and then she slowly but perfectly recovered, the œdema passing away with the other symptoms. The calomel was discontinued in three or four days, and as she became very weak and low, spir. ammon. aromat. in camphor julep was given, with port wine and arrow-root or sago as diet; and afterwards, all the medicine she required was an anodyne to procure rest, and an aperient to regulate the bowels.

*Case 2.*—Jane Sivey, æt. 20, unmarried, and in the fifth or sixth month of her first pregnancy. She was a short, stout woman, and in this case likewise there was much serous effusion, more especially in the legs, and about the neck and face. She had complained of head-ache for a day or two, and had taken opening medicine from a druggist. She was seized with convulsions on the morning of September 10, 1856. The paroxysms were very severe and frequent, with frothing at the mouth, and in the intervals, stertorous breathing. I thought she was not perfectly unconscious between the paroxysms, for she seemed to pay some attention if loudly spoken to, and to feel some pain, which was probably that of commencing labour. Pulse somewhat feeble; pupils natural, but conjunctiva greatly injected. Face, pale. I gave her ten grains of calomel, and one drop of croton oil, and then threw up a turpentine enema; and Dr. Jago, who saw her with me, succeeded with difficulty (because of the œdema) in taking about  $\text{ʒviij}$  of blood from the arm. As there was slight uterine hæmorrhage, and seemed to be regular labour pains, the os uteri was examined several times before midnight, and was found tense and unyielding, barely admitting the point of the finger. The pulse being now more feeble than at the commencement of the attack, the vagina was plugged to prevent further loss of blood. There were few, if any, fits after bleeding from the arm, but she remained in a state of semi-coma, as she had been between

them. About six o'clock next morning the fœtus came away with the membranes entire, and scarcely any blood was lost; but this produced no favourable change in the case, and she died at 11 a.m.

*Secio Cadaveris twenty-eight hours after death.*—The body was still œdematous. The brain and its membranes were healthy and natural, with the exception of a slightly increased fulness of the vessels on the upper surface of the hemispheres, scarcely amounting, I think, to turgidity. The right side of the heart was full of dark coagulated blood; the left side was empty. The lungs and all the abdominal viscera were healthy. The only fact, indeed, disclosed by the post-mortem was that an abnormal amount of serous fluid existed in the skull, in the chest, and in the pericardium. In the skull (at the base of brain), say two ounces; in the chest, twenty ounces; in the pericardium, from four to six ounces.

*Case 3.*—Elizabeth Battar, aged 22, a strong robust woman, was taken in labour with her first child on Friday morning, October 10. I was called to attend her the same day at 8 p.m. The os uteri was then dilated to the size of a crown-piece; the head presenting; the pains were regular, but recurring at long intervals; and I looked for an easy and natural termination to the case. At the end of three or four hours, finding no progress had been made, I gave secal. cornut. This produced considerable increase of pain, but no benefit to the labour, and at the end of eight hours, as there was not the least alteration in the state of things, I left the house. She was seen by my pupil on October 11, and again on the morning of the 12th, and he was waiting with her through nearly all that night; but at four o'clock on the morning of October 13th, he wished me to see her, as the head of the child did not seem to him to descend into the pelvis, and she was very restless and irritable. I found, however, on my arrival, that the os was fully dilated, the head was passing through the pelvis, and the membranes pressing on the perinæum. I hoped to be speedily released by the birth of the child, and thinking there might be an unusual quantity of liquor amnii, I ruptured the membranes; very little, however, came away. She now complained of headache, and fell into a heavy sleep, from which she was roused with difficulty; and at seven o'clock she had a terrible convulsion, which lasted three or four minutes. I immediately took about twenty-eight ounces of blood from the arm, and then tried to introduce the short forceps, which I had with me, but without success, as there was no room for the blades to pass. The bleeding did not produce much depression, for, having lost all control over the mind, she got out of bed, and abused the women around her and myself, in a regular Billingsgate way. At this stage of the case I thought it was desirable to have a consultation, and therefore sent for Dr. Freeman, who kindly came at once. He considered she ought to be delivered if possible, and therefore tried to introduce the forceps, but neither could he succeed for want of space; and as she was very unruly we desisted from the attempt to deliver with instruments, and decided to leave the case to nature for a few hours, especially as there was no return of the convulsions, and we judged that the system was not suffering to any great extent from the head of the child pressing upon the soft parts. The pains, which had in a great measure ceased for some hours, now came on with great strength and regularity, and the patient became quieter; and about nine a.m. she was delivered, without instrumental aid, of a living male child, having the most extraordinary head for length that I have ever seen, and which had evidently been forced through a very strait pelvis. To make this difficult case more trying and complicated, the placenta was retained from abnormal adhesion, and after waiting an hour and a half, it was necessary to introduce the hand into the uterus and separate it, which was not done without considerable trouble. After delivery, and until the placenta was removed, she lost a considerable quantity of blood, and required stimulants for some hours. I saw her again the same evening at seven o'clock. The faintness had passed, the pulse was 130; and in other respects she was going on favourably. I ordered forty drops of laudanum at bed-time, and enjoined quietude.

*Oct. 14th.*—Pulse 90. Tongue slightly furred, but moist; has passed urine twice, and slept most of the night. The mind is in a great measure restored.

*15th.*—Pulse 110; but in other respects the case is doing well. The mind is fully restored. To have gruel and bread diet.

*16th.*—Pulse 120. There is some cough and bronchial

symptoms. Does not feel so well as yesterday. Bowels moved by castor-oil. To have mist. salin. and small doses of ant. tart.

17th.—Pulse 120. Cough is better, and the patient is improving and gathering strength; but she did not send for the medicine, and seems to have done very well without it. To have better diet, mutton, etc. She was seen twice after the above date, and then, as she had no complaint to make, and was recovering most favourably, I struck her off my visiting list. The quickness of pulse persisted, but was probably owing to the loss of blood which had been sustained.

*Remarks.*—In two of the above cases, it will be observed, the women had considerable serous effusion into the cellular tissue, and in one of them (the fatal one), as proved by the post-mortem, into all the visceral cavities, as skull, pericardium, etc. Now, as effusion at the base of the brain is believed to be a centric cause of these terrible convulsions, and the poisoned state of the blood, which we are told always exists with this effusion during pregnancy, is said to be a sufficient cause itself; it is probable that in these cases the convulsions were produced by their united operation: but of course the effusion, if it existed in both cases, by causing pressure on the pons and medulla was an all-sufficient cause. In thinking over the other case since it occurred, I am disposed to attribute the one solitary paroxysm to anxiety on account of the prolonged labour, and our not being able to afford relief; for the patient was very impatient and irritable. As regards the treatment adopted, I am inclined to think that bleeding saved the lives of the two patients who recovered. The mercurial treatment is recommended by some writers, but I have no experience of its utility. It might help the case in which it was used by stimulating the absorbents as in ordinary dropsy. In the fatal case, I think the patient ought to have been bled more freely; and it is probable she also would have been saved, if the feeble pulse (perhaps masked by the œdema) had been disregarded.

THE NEW OPERATION FOR GLAUCOMA.

THE readers of the Statistical Reports of operations at the Ophthalmic Hospital, which have recently appeared in this Journal, will have noticed frequent mention of "Excisions of portions of the Iris in cases of Glaucoma." To the uninitiated the mention of such a procedure must have caused considerable astonishment, as indeed it appears to have done in more than one quarter where better information might have been expected. The new operation in question, and which we may remark, *en passant*, that we described about six months ago, is one originated by M. Graefe of Berlin, and practised by him on a very extensive scale. Its principle, however, as we shall have to show, have not been wholly overlooked by former ophthalmic Surgeons, though none certainly ever proposed so bold a manner for its carrying out. It has long been well known that in certain forms of ophthalmia, some chronic and others very rapid in their course, the globe coincidentally with intense pain, and loss of sight, becomes very hard, its humours meanwhile undergoing a peculiar loss of translucency. In these cases it is evident that there is increased tension from increase of the fluid contents of the strongly encapsuled globe. To relieve this tension by paracentesis has long been acknowledged to be an important aim in their treatment, though now in looking back on actual practice it must be acknowledged as strange that so palpable an indication was very rarely carried out. It had, however, its strenuous advocates. Without stopping to inquire in what tissue of the eye the primary inflammation occurred, it will be sufficient for our present purpose to state that the increased tension of the whole globe was an amply abundant explanation of the loss of vision, without supposing any actual disorganization of the retina. The disease we allude to has been

known, for want of a better, by the name of glaucoma, acute or chronic, as the case might be, the acute often destroying sight in a few days, the chronic requiring as many months.

Now it is in these cases that Graefe had advised the bold measure of a free incision into the eye, the evacuation of the whole of the aqueous humour, and the removal of from a fifth to a third of the iris. In explaining its good effects as due to relief of tension, we beg to be understood as offering what has appeared to English observers the most probable; not as representing its originator's views. The mode in which Graefe performs the operation is by passing a Beer's cataract knife into the sclerotic, about a line's distance from the margin of the cornea on the outer side, and having directed it forwards into the anterior chamber, cutting upwards so as to make an incision nearly half an inch in length. Through this the iris readily prolapses, or if it do not, is easily drawn by forceps, and a portion of it, varying from a fifth to a third of its whole, is cut away. The remains of the prolapsed iris is left in the wound. This is a fair description of the operation, as we have repeatedly seen it performed by Mr. Bowman, who was, we believe, the first to adopt it in this country. Mr. Bowman, however, prefers, instead of operating on the outer side of the eye, to cut obliquely upwards. This secures that a portion of the large unshapely pupil shall be concealed under the upper lid. Mr. Critchett has endeavoured to carry out what he believes to be the principle of Graefe's, by a somewhat simpler procedure. He merely punctures the cornea, and draws out a portion of iris, performing, in fact, an operation for a large artificial pupil. He leaves the iris in the wound, holding that so left it secures a certain amount of draining away of the aqueous humour, acting as a sort of tent in preventing the healing of the wound.

Of operations of this class, performed more or less exactly after one or other of the methods described, probably not fewer than twenty have been done at the Moorfields Hospital during the past nine months. Both Mr. Critchett and Mr. Bowman have also, we believe, repeatedly operated in private in the same manner. Of the Hospital cases careful notes have been preserved, and will no doubt be brought before the Profession in due time. Meanwhile, as regards results, we believe we may state that in cases of acute glaucoma, those, for example, in which the sight has been very seriously damaged, in the course of twelve hours, or at most a few days, the operation is of the greatest possible benefit. Its introduction into practice is to be hailed the more gladly, because it is generally acknowledged that in this affection constitutional treatment is of very little avail. The only expedient really efficient for its relief formerly known was paracentesis of the globe, and of this, if not repeated at frequent intervals, the benefits, as might be expected, were too often only temporary. It did not secure a sufficient permanent escape of fluid from the over-distended globe. In all the cases of acute glaucoma in which we have seen it practised, the relief to pain has been prompt and complete, whilst in most the sight has been much improved. It would appear that improvement in vision may be expected to continue for two or three weeks afterwards, when if the case have done well it becomes stationary and permanent. Of the advantage of the operation in cases of chronic glaucoma, by far the larger class, we must speak much more cautiously. Some cases have seemed to derive benefit, others not. The matter is yet *sub judice*. Enough has, however, certainly been proved in favour of the operation to merit for it a patient trial from British Ophthalmic Surgeons. The disease, be it remembered, is one otherwise hopeless, or nearly so.

One acute case in which Mr. Critchett operated made a deep impression upon us, as demonstrating that the defective vision does really in a large measure depend upon over-distension, and that upon the escape of fluid depends the relief obtained. A healthy looking man, of about 35, had lost the left eye from an injury some years ago. His sight with the right had been perfect until within a few days of his admission, when intense pain suddenly set in, and he rapidly became almost blind. The surgeon whom he consulted pushed a rapid course of mercury to slight ptyalism, but without benefit, and then sent him to Mr. Critchett. The globe was then tender, very hard, intensely painful, and all its humours looked muddy and of a greenish yellow. He was at once placed under chloroform, the lost eye excised, and inflamed one operated on after the manner described. The restoration of transparency to the humours was immediate

on the escape of the aqueous, a slight film on the capsule of the lens, however, still remaining. All pain was relieved, and during the next three weeks the man's sight continued steadily to improve.

Mr. Bowman states, that he has noticed almost invariably, even in chronic cases, that mobility is restored to the pupil by the operation, where it has been lost before.

Here for the present we leave this interesting subject, hoping soon to see from the pen of one or other of the surgeons mentioned, an authentic, and detailed account of their experience respecting it.

## HOSPITAL NOTES.

### STRICTURE OF THE URETHRAL ORIFICE, FOLLOWING AMPUTATION OF THE PENIS.

A very instructive case has recently left Mr. Erichsen's wards in University College Hospital, illustrating the necessity for the care which Surgeons devote to prevent the urethra from contracting after amputation of the penis. We have often had occasion to allude to the different expedients;—free removal of integument; cutting through the corpora cavernosa, higher up than the corpus spongiosum; introduction of a seton, etc.—which are adopted by different Surgeons with this object in view. In the case alluded to, the penis had been amputated six years ago for cancer, and the man, now aged 73, came under Mr. Erichsen's care in November last, on account of a stricture at the orifice which had resulted, and as the consequence of which extravasation of urine had occurred. There were no fewer than seven fistulæ in the perineum, and much adjacent induration and thickening. All attempts to cure the fistulæ by dilating the constricted orifice having failed, perineal section was performed, with the intention of securing a single direct and central false passage. The man recovered well, and has been very greatly relieved by the measures adopted, most of the old fistulæ having already closed, and the irritation subsided.

### BICHROMATE OF POTASH AS AN ASTRINGENT.

Mr. Lloyd, in some remarks to his class the other day in his Syphilitic Ward at St. Bartholomew's, spoke very highly of the good effects which he had obtained from solutions of the bichromate of potash used in cases requiring astringents. We understand that the same remedy is much employed at the Liverpool Infirmary, for the removal of fætor from sloughing wounds, etc. The power of the solution as a preservative fluid is well known. Mr. Lloyd stated that he had begun with five grains to the ounce, but increased it to a drachm. In one case of very chronic leucorrhœa, in which the lips of the os uteri were swollen and spongy, it had effected a complete cure, after many other remedies had wholly failed. It is being used at St. Bartholomew's as an application to warts, etc.

### REMOVAL BY LITHOTRITY OF A PORTION OF GUTTA PERCHA BOUGIE, BROKEN INTO THE BLADDER.

We recorded, about a year ago, a series of cases in which portions of gutta-percha bougie and other foreign bodies, had been removed from the bladder. In several cases lithotomy had been performed for their extraction, but in one or two the fragment had escaped spontaneously. Our conclusion was that lithotomy ought never to be hastily had recourse to, but that whilst no ill symptoms were set up, the surgeon should be content to wait, and should meanwhile endeavour, by dilating the urethra and injecting the bladder, to render the spontaneous passage of the foreign body more likely to occur. There are two events, either of which ought to induce the surgeon to at once resort to a radical measure of relief; and these are, 1st, the existence of severe vesical irritation; and, 2nd, the formation of a calculus around the foreign body. So long as a bit of gutta-percha, etc. remain smooth, there is hope both that it will not irritate, and that it may at some happy moment get its end pushed into the urethra; but if, on the contrary, there be evidence of its having become encrusted, the chance of favourable progress without interference is vastly diminished. We make these remarks apropos of an instructive case recently treated by Mr. Birkett, in Guy's Hospital. The patient, a young and

healthy man, was admitted a month after having broken a gutta-percha bougie into his bladder, about two inches having been retained. On using a sound Mr. Birkett easily detected the fragment, which was already encrusted over. An attempt was made to extract it by means of the lithotrite, but failing, on account of its shape (having probably been seized crosswise) it was simply crushed. The lithotrite was used again a week afterwards, and following each employment of it, fragments of calculus and portions of the bougie came away. A good deal of irritation was caused, but not such as to prevent a third repetition of the crushing, ten days after the second. After the third operation he was for three weeks very ill, with inflammatory disturbance and abdominal pain, which only terminated when one evening he passed a calculus by the urethra, which was followed by the flow of three or four ounces of well-formed pus. After this the man made a rapid recovery, and all urinary symptoms ended. It was quite evident that there had been an abscess in the parietes of the bladder at some part, probably near or in the prostate. Whether the calculus had been lodged in the abscess cavity, or whether, in being roughly forced over its surface, it had merely been the means of rupturing it, must be left to conjecture.

### TRACHEOTOMY IN CANCER OF THE LARYNX.

Amongst the more interesting of the specimens brought before the Pathological Society on Tuesday evening, were two specimens of cancer of the larynx, in the first of which the patient had been allowed to die unrelieved, and in the second life had been prolonged for upwards of a year by tracheotomy. The principle is an important one to establish in practice, that whenever death is in prospect from mechanical occlusion of the larynx, the operation should be had recourse to without regard to the exact nature of the cause. Its being cancer, or, what is more usually the case, its being suspected to be cancer, ought not in anywise to prevent this being done. A remarkable case is brought to our memory, which we witnessed some years ago, under Mr. Hilton's care, at Guy's, which bears on this point. The disease was not cancer of the larynx itself, but of one tonsil, involving the pharynx pressing down upon the larynx, and threatening complete occlusion. A portion of the growth had been excised for microscopic examination, and had been declared to be cancer. Suffocation being, however, imminent, Mr. Hilton performed tracheotomy, and the man, who recovered well, ever after wore the tube. The singular feature in the case now followed. The growth gradually diminished, and finally disappeared wholly. The man could now breathe through the natural passage, and used to wear the tube covered; he, however, refused to have the tube taken away. It was thought that the diagnosis had been erroneous, and that inflammatory swelling had been mistaken for cancer, but that it was probably not so seemed likely when we last saw the man. After the enjoyment of about a year's good health he presented himself to Mr. Hilton at the City Hospital for Chest Diseases, with numerous scattered tubercles in the skin. Some of these were of large size, and their aspect was exceedingly similar to that of examples of multiple cutaneous cancer. Mr. Hilton advised him to come into Guy's, to have one at least of the tumours excised for examination, but this he declined, and we shortly afterwards lost sight of him.

### TURPENTINE AS A DETERGENT.

We noticed in use the other day at the Dreadnought the oil of turpentine as a wash for stumps, etc., which may have got coated with plaister or other adhesive material. It is, we believe, also used at several other hospitals for the same purpose. The part is freely washed with tow dipped in turpentine. It does not appear to unduly irritate, but restores a healthy glow to the cutaneous surface, and the patients describe its effects as being pleasant rather than otherwise.

### DEATH FROM SYPHILIS.

Cases in which death from syphilis actually occurs are known to be rare. Mr. Chippendale, one of the House-Surgeons at St. Bartholomew's, mentioned to us the other day the particulars of the following instance of it which had just happened. The patient was a man aged 27, who had been repeatedly an in-patient during the last three years, suffering from various forms of tertiary symptoms. He had

taken iodide of potassium most largely, and often with temporary benefit. There had been very extensive destruction of the pharynx and soft palate, and a large portion of the upper maxilla had necrosed and come away. He had ulcerated nodes in various parts. His voice had for long been hoarse, and finally, in conjunction with those of pulmonary phthisis, symptoms of laryngeal ulceration manifested themselves. Under this combination he at length sank exhausted. At the autopsy the lungs were not allowed to be examined, but most extensive disease of the larynx was ascertained to exist. In an abscess on one side a portion of loose cartilage was found. The case furnishes us with an example of a class of cases, now fortunately very small, in which constitutional syphilis resists all the usual specific remedies, or if it do not wholly prove intractable, relapses occur so frequently and are of such severity, that the result practically amounts to a successful resistance. It is in such as these that the fumigation plan sometimes displays its advantages.

#### NOTE ON THE LONG-CONTINUED USE OF BELLADONNA.

A class of cases in which these solutions are exceedingly useful are those in which either a central opacity of the cornea exists, or the iris is tied down by adhesions, and the pupil partially obliterated. Under either of these circumstances, artificial dilatation of the pupil often suffices to afford to the patient vastly improved vision. These objects the solution of belladonna or of atropine will accomplish for any length of time. The fact is well vouched for by writers, and is frequently confirmed in practice, that habit does not diminish its influence. We have known patients continue its employment for ten years or more, its activity being just as apparent at the end of the time as at first, and no increase in the strength of the solution having been required. It may, perhaps, be deemed rather clumsy practice to set a man to put drops into his eye every day for the rest of his life, when a simple operation for artificial pupil might at once secure the object desired; but still there are circumstances, and those not of unfrequent occurrence, in which the former practice is preferable to the latter. The one requires a skilled operator, whilst the other is devoid of the slightest risk, and open to the adoption of any one. At any rate it is to be regretted that the efficiency of the plan by the permanent use of belladonna is not more widely appreciated than it is. The cases scattered up and down the country are probably not a few in which great benefit would be derived from its adoption.

#### HOSPITAL PHARMACOPEIA.

We extracted last week from the Pharmacopœia of the Moorfields Ophthalmic Hospital a formula for atropine drops. It may perhaps suit our readers' convenience if we group together such other formulæ as may seem suitable for quotation which have reference to this specialty. The following are from the Pharmacopœia of the Hospital referred to.

##### BELLADONNA DROPS.

These consist of twenty minims of the liquor belladonnæ to an ounce of distilled water. Atropine solutions are far more cleanly applications, and, as they keep better, their efficiency is more to be relied on. Atropine may not, however, be obtainable under all circumstances, and recourse must then be had to belladonna.

##### HYDROCYANIC ACID DROPS.

Very little efficiency is, we believe, thought to belong to hydrocyanic acid as a topical application to the eye. A formula, however, for drops containing it stands in the Pharmacopœia. It is one drachm of the dilute acid (Ph. Lond.) to seven of water. It is used in cases of irritable ophthalmia, but is rarely ordered.

##### SULPHATE OF COPPER DROPS.

The chief use of the sulphate of copper is as an application to granular lids, and for this purpose the crystal is employed. In this form, we believe, we may write that it still maintains its old reputation, as superior to all of the very numerous caustics which have been recommended in the treatment of this troublesome affection. After touching the lining membrane of the lids with the copper it is a good plan to smear the integument of the lid with a moistened stick of nitrate of

silver. The strength of the sulphate of copper drops, which are employed in certain cases of thickened conjunctiva, &c., is two grains to the ounce. These drops are, however, not nearly so frequently used as those of either the nitrate of silver or the sulphate of zinc.

##### BICHLORIDE DROPS.

These are, like the following, used chiefly in cases of corneal opacity, after the subsidence of all inflammatory symptoms, and with the intention of promoting absorption. Their strength is one-eighth of a grain of the bichloride of mercury to an ounce of distilled water.

##### IODIDE OF POTASSIUM DROPS.

The strength of these is three grains to the ounce. Their reputation is, we believe, about equal to that of the above, and respecting the efficiency of neither is a very confident opinion entertained.

##### NITRATE OF SILVER DROPS.

One grain to the ounce of distilled water is the strength of nitrate of silver drops employed at this Hospital. These drops are held to be an absolute specific in cases of catarrhal ophthalmia, but are very rarely used in any other form. They will cure also the purulent form, but against it the alum is equally, if not still more efficient. With these two exceptions there is scarcely a form of acute inflammation of the eye in which the Surgeons to this Hospital do not strongly disapprove of the use of topical stimulants. In cases of catarrhal ophthalmia, on the contrary, so marked is the effect of the nitrate that constitutional measures are hardly ever thought of. The cure is held to be likely to occupy about the same time that the disease had previously existed, the latter being much more quickly curable if it come under the proper measure in an early stage.

##### ALUM LOTION.

The strength of this lotion is eight grains to the ounce. It is specific against the purulent ophthalmia of infants if properly and freely used. It is also occasionally ordered in other forms of muco-purulent inflammation of the conjunctiva. A stronger alum lotion (lotio aluminis fortior) has a scruple to the ounce.

##### VINEGAR LOTION.

This lotion is almost exclusively employed to remove lime from the eye. Its strength is half a drachm of distilled vinegar to an ounce of water. Of course the sooner it is resorted to after the accident the better. It should also be very freely used, the lids being everted, and well washed.

##### LEAD LOTION.

Two grains of the acetate of lead, dissolved in an ounce of distilled water, is the formula for this invaluable lotion. It may be used with the happiest effects in many forms of conjunctival inflammation in which stimulants would be injurious. Very frequently after other lotions have effected a certain amount of benefit, but their good influence appears to have ceased, the use of lead will serve a most opportune purpose. Although the importance of the accident has, we believe, been much exaggerated, yet it is of course desirable to avoid the employment of this salt in all cases in which the cornea is actually ulcerated, for fear of its deposition in the cicatrix. It is to be observed, however, that as a lotion it is not intended to be actually dropped into the eye, but only applied to the lids. This Pharmacopœia does not contain any formula for drops in which lead is an ingredient.

##### LEAD AND OPIUM LOTION.

This consists of three minims of tincture of opium to an ounce of the above-mentioned solution of the acetate of lead.

##### LOTION AND DROPS OF THE SULPHATE OF ZINC

The strength of this lotion, as of nitrate of silver drops, is one grain to the ounce. It is employed in cases of weak eyes, with relaxed conjunctiva, and in those of inflamed lids. At this strength it is a milder stimulant than either the alum lotion or the nitrate of silver drops. When directed to be used as drops, the strength of the sulphate of zinc solution is two grains to the ounce.

##### OINTMENTS FOR TINEA TARSI.

Almost the sole use for ointments in ophthalmic practice is against tinea of the lids. For the treatment of this most

troublesome disease, several formulæ are contained in the Moorfields Pharmacopœia, most of them having some form of mercurial as their active ingredient. We have the unguent. hydrarg. nitr. dil., the strength of which is half a drachm of the nitrate of mercury ointment to seven drachms of lard; the unguent hydrarg. mitius, which is a drachm of the nitrate of mercury ointment to nine of lard; the ung. hydrarg. nitrico-oxyd. dil., which consists of a drachm and a half of the ointment of the nitric oxide to six and a half of lard. Of those not containing mercury the compound zinc ointment is the only one; its formula is equal parts of the zinc and compound lead ointments; it is, we believe, very rarely used. The dilute nitrate of mercury ointment is the one which enjoys by far the largest amount of confidence.

Very little, indeed, of special pharmacy is required in the treatment of diseases of the eye. The drugs in more frequent use are very few in number, and its dispensing is mostly very inexpensive. Tonics, indeed, constitute almost the only costly ones required, and of these, by the Surgeon who thoroughly understands the use of opium, turpentine, iron, and nux vomica, the more expensive may be almost wholly avoided. It is indeed almost only after extractions, in certain forms of strumous ophthalmia in children, and in others of pain in the eyeball, associated with neuralgia in adults, that quinine becomes absolutely indispensable. In the very numerous class of cases in which failing sight is dependent either upon chlorosis, asthenia lactantium, or other source of debility, more may be done by steel and nux vomica, than even with bark. There is nothing in the list of tonics, alteratives, or stomachics in use at this Hospital, which is peculiar, and which may not be well deferred for consideration to another place. We find, however, in the Pharmacopœia a formula for a

#### TINCTURE OF STRYCHNIA,

which we may here introduce. It consists of a grain of strychnia, to an ounce of tincture of orange peel. It may be questioned, however, whether this tincture is so efficient in all respects as that of the nux vomica itself, and is certainly not more convenient in use, while much more expensive.

Great praise is due to the Medical officers of the Moorfields Hospital, on account of their steady adherence to simplicity in prescribing. Of the formulæ in their Pharmacopœia very few, indeed, contain more than two active ingredients, most of them possessing but one; and very rarely, indeed, do the patients' letters exhibit any complicated prescriptions. When opiates are required, the liquor opii sedativus is usually preferred, as being at once more efficient, and less likely to disagree with the stomach than any other. This drug is largely used in cases of strumous ophthalmia in children, properly reduced in dose, being not more prone to disagree, while much more reliable than either tincture of hyoscyamus or paregoric. Diarrhoea is held to be one of the main indications for its use, and if the bowels are constipated it is never given, at least until free purgation, by scammony and calomel, has been first effected. In cases in which the intolerance of light is great, the bowels irritable, and the child very restless, a full opiate at night, with bark in the day, is often very quickly effectual. The form of bark usually prescribed to children is the liquor cinchonæ, prepared by Battley, but for adults quinine itself is held to be much more efficient. The chlorate of potash in full doses, as an alterative saline, in certain cases of pustulo-strumous ophthalmia, has recently come into much favour. A detailed examination is, however, being made as to its merits, and as to the class of cases for which it is best suited, and at present it would be premature to speak dogmatically.

#### A SUMMARY REPORT ON BLOODLETTING IN EPILEPSY.

—The following is the entire report presented by the chairman of a special committee of the Indiana State Medical Society, appointed to consider the question of "The Effects of Bloodletting in Epilepsy, Convulsions, etc.:"—"Having examined the literature of the subject, I find that none of our recent authorities have any confidence in bloodletting as a remedy for epilepsy, but, on the contrary, an opposite treatment is advised—the disease being one of debility, instead of plethora. The question being altogether a negative one, and unsuitable for a report, I wish to be discharged from further duty."

## Medical Times & Gazette.

SATURDAY, JANUARY 9.

#### THE ENGLESHAM POISONING CASE.

THE case of poisoning by prussic acid which has been recently tried on the Glasgow Winter Circuit, and has ended in a conviction for murder, presents some features of interest in reference to the circumstantial and medical proofs of death from this poison. We will first deal with the general evidence, as by this the administration of poison appears to have been as clearly traced to the prisoner as if the act had been proved by the testimony of an eye-witness.

The deceased, Agnes Montgomery, was 27 years of age, an active woman of good health, and never subject to fits or convulsions. She was seen by her sister in her usual health about half-past four o'clock p.m. on the 13th of September, 1857. Soon after five o'clock, in consequence of hearing a moaning noise, the witness entered her room, and found her sitting in a chair insensible, with her head leaning on a table, her right hand hanging down, and her left hand in her lap. Her eyes were prominent, fixed, and staring, and a thick "slavery froth" tinged with blood was issuing from her mouth. Her face was bluish red, and swollen,—there was difficulty of breathing,—she gave heavy sighs, with occasional sobs; got worse and died. It was twenty minutes past five when her sister entered the room, and the deceased died about six o'clock, thus making the duration of the case, so far as it was witnessed, forty minutes; but the deceased had probably taken the poison from five to ten minutes before she was seen by her sister. A Medical man saw deceased about half-past five. His evidence as to her condition confirmed that of the non-professional witness. The eyes were staring and motionless, and the pupils dilated; she breathed slowly, and with difficulty, and the respirations were rather deep (heaving); the pulse was between seventy and eighty; there was coldness of the skin, with spasmodic contraction of the jaw. She had bitten her tongue, and this had occasioned the bloody appearance of the froth which issued from her mouth. This witness appears to have had no suspicion of poisoning, and observed very little; for while it was clearly proved that the right hand of deceased was firmly clenched, and the left foot quite stiff, he did not observe, and could not speak to the condition of the feet and hands. He admitted he was told that the deceased was quite well at five o'clock, i.e. within half an hour of the time at which he saw her in this dying condition. He certified that she had died of *apoplexy*, and gave no notice to the authorities of this very sudden and suspicious death. Upon this medical certificate the deceased was buried on the 17th September, but in consequence of some rumours, the body was exhumed and inspected on the 30th, i.e. seventeen days after death.

The inspection was made by Dr. Mackinlay, of Paisley.

The body was much decomposed, the face swollen and black, the fingers of the right hand were firmly bent inwards, the lungs were shrunk, the heart normal and empty. The liver, spleen, and kidneys presented no unusual appearance; they were decomposed.

On opening the stomach, there was an odour resembling that of prussic acid. The inner coat was reddish coloured, and the stomach was quite empty. The intestines, with the exception of slight redness externally, were in a normal condition.

The chemical evidence rested upon the experiments of Dr. Mackinlay and Dr. Douglas MacLagan, of Edinburgh. Dr. Mackinlay stated at the trial, that the stomach was treated by several tests (not mentioned in the report), and the conclusion which he and his son (another witness) drew, was that prussic acid was present in the stomach. Portions of the liver, heart, kidneys, spleen, and contents of the intestines were tested; but the results obtained were not such as to warrant a positive opinion that prussic acid was present in any of them. This analysis appears to have been made during the first week in October. Parts of the viscera were submitted to Dr. MacLagan on the 8th of October, and the first report of his analysis is dated the 10th. His attention was specially directed to the detection of prussic acid as the suspected cause of death. The bottles were sealed and labelled. In that containing one half of the stomach, there was no odour of prussic acid, the smell being merely that of sour semi-putrescent animal matter. The vapour evolved contained none of the poison, and it was only by distillation and by the aid of one test (that which is called the sulphur test) that an exceedingly minute trace of prussic acid was detected. The other tests for the poison gave no reliable results. There were 350 grains of liver, from which about a drachm of blood was obtained and tested. The blood gave with only one test (the sulphur test) a trace of the poison, but the experiment was too unsatisfactory to be depended on alone. The liver itself was not tested. On the 10th November, i.e. about a month afterwards, Dr. MacLagan examined one half of the heart, one half of the spleen, one half of the kidney, and one and a half inch of the duodenum with about ten inches of the small and four inches of the large intestines. There was no odour of prussic acid in any of these parts. The sulphur-test applied to the vapour issuing from the spleen produced results furnishing an unequivocal proof of the presence of prussic acid; the other tests failed to show its presence in the spleen, and in none of the other organs could any trace of the poison be found.

The accused was connected with the act by the following circumstances. On the 12th of September he caused a purchase of prussic acid (two drachms) to be made by a carrier on false pretences; this was delivered to him on the morning of the day on which the deceased died (the 13th). He was with one of the witnesses until ten minutes before five in the afternoon. He went towards the deceased's room; some beer was procured by his order—a noise, as of some one falling and being dragged along the floor, was afterwards heard in deceased's room, and shortly after this, i.e. a little after five o'clock, and after this noise had been heard, prisoner was seen leaving the deceased's room, and heard to lock the door after him. He took the key, which was subsequently found in a spot where he had had an opportunity of placing it; and some broken glass was found (the glass of a phial) in a garden-path adjoining. He gave untrue statements of his proceedings, and no satisfactory account of what had become of the prussic acid which he had caused to be purchased. There was an eye-witness to the act of administration, but, as this was a child of only three years of age, her evidence could not be received. With the facts thus placed

before them, the jury could, as we think, come to no other conclusion than that the prisoner was *guilty*.

The learned judge, in charging the jury, said "There had been a great deal of medical theory relied on in this case, but the jury, as men trusting to their general knowledge, would feel that that which they had to attend to were the actual facts of the case. And if they were satisfied that those facts led to a conclusion against the prisoner, neither the theory of the absence of motive, nor any medical speculations, could alter or prevent them from falling back on the actual facts." There was wisdom in these observations, and they no doubt had their proper effect in directing the jury to a just verdict.

The symptoms described by the witnesses who saw the deceased are in accordance with those which prussic acid is known to produce:—they are unlike those of apoplexy or epilepsy, irrespective of the consideration that these diseases do not commonly attack persons of the age of the deceased at once, without leaving well-marked appearances on the body, or without warning, and they do not destroy life so rapidly. The deceased is in her usual health about five o'clock, and is dead at six o'clock, without any appearance in the body to explain this sudden death in a healthy person. We think that without any chemical evidence at all, there was enough in the "actual facts" of the case to justify the verdict of the jury.

The chemical evidence was in some respects conflicting. The two witnesses who examined one part of the stomach deposed to the smell of prussic acid and to the discovery of this poison in the organ, but they could not detect it in the spleen or other viscera. A few days afterwards the remainder of the stomach was examined by an experienced chemist, who could not perceive any odour in it, and who could procure by one test only, an exceedingly minute trace of the poison. An analysis of one half of the spleen by the same gentleman five weeks after the disinterment of the body showed the presence of prussic acid, while the other half, which was analysed immediately after the exhumation by the witnesses who made the inspection, yielded results which could not be relied on. These differences were of course dwelt upon in the defence, and would have afforded, no doubt, a wide field for chemical discussion and dispute had the circumstances of the case and the social position of the poisoner been favourable to such a gladiatorial exhibition. There was no accord even on the strength of the prussic acid with which the deceased was supposed to have been poisoned; for while Dr. Mackinlay gave its strength at four per cent., Dr. MacLagan made it about two and a half per cent. of anhydrous acid. Dr. Penny was called to explain, and if possible to reconcile these chemical differences; but in spite of his evidence the fact still remained, that if prussic acid was found in one half of the spleen five weeks after the exhumation of the body, it ought to have been clearly and distinctly found by those who examined it immediately after the body was exhumed. It was suggested by defendant's counsel, that if not then found in the spleen, what reliance could be placed on its alleged discovery in the stomach, in which Dr. MacLagan, analysing one half about the same period, could scarcely speak to a trace, and that only by the use of one most delicate test?

We do not advert to these scientific differences because we entertain any doubt about the sufficiency of the evidence for conviction, but rather because they gave to the counsel for the defence the opportunity of pressing upon the jury Orfila's view, that prussic acid in small quantity may be spontaneously generated by decomposition in the dead body. At the trial of Tawell at Aylesbury, in 1845, Sir Fitzroy Kelly took a wider basis, upon the advice of the chemists retained for the defence of that criminal. He assumed the presence of

a sufficient number of apple-pips in the stomach of Sarah Hart to make up one grain of anhydrous prussic acid! Here the counsel for the prisoner, who, we are bound to say, acted with great discretion and propriety, had to deal only with traces of prussic acid, and the theory of Orfila naturally presented itself to his mind when the two halves of the spleen gave such conflicting results; the prussic acid only manifesting itself in an unequivocal manner in this organ more than a month after the first analysis had failed to reveal it! We have been induced to look at what Orfila says on the subject, and we can find nothing satisfactory. This alleged spontaneous generation of prussic acid in the dead is a mere speculation without a shadow of proof or even probability. In the last edition of his excellent work on Toxicology, Orfila puts his proposition in an evasive and negative form. Thus, he says, "It is *not* proved that prussic acid may not be produced in the body at a certain stage of putrefaction." It is not customary to prove negatives of this kind, and the same proposition might be as safely put regarding arsenic, phosphorus, and other poisons! He does not mention a single fact which renders his theory even probable, and he takes away the whole force of its application to the Glasgow case by the remark, that he does not intend this doctrine to be applied to the denial in all cases of poisoning by prussic acid, for the *symptoms* and *appearances* may be such as prussic acid would produce, etc. We may, therefore, safely wait until some probability has been given to this theory by actual observations. Dr. MacLagan justly observed, that if it were true, analysts would be frequently meeting with prussic acid in the dead body, whereas it is never found excepting in those cases in which circumstances concur to show that it must have been taken and caused death.

We shall only further remark of this case, that the facts as recorded throw some light on certain disputed points connected with poisoning by prussic acid. Putrefaction was not retarded, but, in the short period of a fortnight, had evidently gone on to a great extent. There were appearances of tetanic spasms affecting one hand and foot, and continuing even in the grave for a period of seventeen days, in spite of putrefaction. Among the symptoms there was no "death-shriek!" Our readers may remember that Sir F. Kelly insisted upon the absence of this as a proof of the innocence of the culprit Tawell, and to show that his victim, Sarah Hart, had died a natural death! There was no medical quibbling there about the condition of the heart, the cavities of which were quite empty—or of the spinal marrow, which was not examined, and no medico-legal quibbling about the amount of poison found in the body. In Tawell's case, a grain of anhydrous prussic acid was contained in the stomach. This was proved, not by one, but by all the tests in an unequivocal manner. It was contended, however, in defence, that no one had died from so small a dose as this, and that no person could die from less than that which had been known to prove fatal. Hence it was argued, It is not enough to find prussic acid; you must produce from a dead stomach a sufficient quantity to prove fatal to another adult! In the Glasgow case, the witnesses spoke to the presence of traces only, and the counsel for the prisoner had the good sense to know that the quantity found was immaterial, provided it was clearly detected.

There was no shedding of tears by the counsel in defence, as at the memorable trial of Tawell; no asseveration of the innocence of his "unhappy and persecuted client"—the prisoner—as in some other remarkable cases; but a very proper and sensible appeal to the jury, to which no medical witness could take exception. From these facts we draw one of two conclusions: either that Scotch barristers who defend criminals are better informed on questions of poisoning, than certain

members of the English bar; or that they have less professional duplicity, and feel it a disgrace to deal with a defence upon grounds which are at once repugnant to common sense and opposed to a safe administration of the criminal law.

### THE WEEK.

From additional particulars which have reached us in reference to the late proceedings instituted at Bridgewater against Mr. Henry Symes, we are compelled, however reluctantly, to allude to the subject more fully than we had intended to do. It appears to us that that gentleman has been made the victim of a very cruel persecution, and it will be no novelty to our readers to be informed that Mr. Symes's persecutors are the Guardians of the Poor-law Union, of which he is one of the Medical officers; nor will it excite much surprise that the agents of the Poor-law Board have joined the Guardians in their crusade against him: but it will excite both surprise and regret to be informed that two of the chief witnesses arrayed against him were Medical practitioners, living in the same town with himself. He has been exposed to two judicial investigations; one before a Coroner's jury, by which he has been entirely exculpated; and another before an Inspector, sent down by the Poor-law Board to investigate the same case. The circumstances under which Mr. Symes has been dragged, almost as a criminal, before a Coroner's jury, are so extraordinary, that if similar proceedings should become common no Medical man's character will ever be safe. It appears that he received an order, in April last, to attend a pauper patient, of dissipated character and very irregular habits, who was suffering from hypertrophy of the heart and valvular disease, but who was nevertheless able, like many patients similarly afflicted, to walk about from place to place, and who accordingly came as an out-door patient to Mr. Symes's house. That gentleman appears to have treated the case in a very appropriate manner, as far as we can perceive, and to have enjoined the observance of strict repose; in spite of which the man is stated to have pursued his usual loose and erratic habits, and it is actually deposed, in evidence, that while under treatment he entered himself as a sailor on board a coasting vessel, and in that capacity assisted in unloading ten thousand bricks. Under these circumstances it cannot astonish any one that a man labouring under hypertrophy of the heart, with valvular disease and general dropsy, should get worse under any treatment, however judicious; and we accordingly find that he was at last admitted into the Infirmary of the Workhouse in a state of general disease, under which he rapidly sunk. In this brief history there seems nothing whatever to fix upon any practitioner a charge of unskilfulness or neglect; yet we find a Coroner's jury solemnly assembled to investigate the cause of the man's death, and in effect almost to try Mr. Symes for manslaughter! The evidence directed to this object, however, entirely broke down, and a verdict of "Death from Natural Causes" was returned. Not satisfied with this result, the Guardians, assisted by the two Medical gentlemen to whom we have alluded, now solicit and obtain an investigation against Mr. Symes on the part of the Poor-law Board; the whole case is, tried over again, and the decision at present rests with the authorities at Whitehall. In addition to the case of the man who died of the diseased heart, another case was trumped up against Mr. Symes before the Poor-law Commissioner. In the latter instance, Mr. Symes was charged with neglecting a pauper who was suffering from some chronic inflammation of the knee-joint; but although an attempt was made to prove that the man was visited only twice in seven weeks, it was distinctly shown that Mr. Symes repeatedly went to the man's house, *but was re-*

*forced admission by his wife*, who had pawned some article belonging to one of Mr. Symes's servants, and who was afraid of detection. Of the treatment pursued in this latter case by Mr. Symes, his two Medical opponents have expressed an unfavourable opinion; but it is a curious circumstance that when the patient came under the treatment of one of these adverse witnesses, precisely the same treatment was pursued as that which was adopted by Mr. Symes. The whole affair has thrown great discredit upon the state of Professional feeling at least in two quarters, in the town of Bridgewater. Whatever may be the cause of animosity existing in the minds of the general public against a Medical Practitioner, it does not become any of his Professional brethren to join the outcry against him, and we hope that the proceedings to which we have now alluded may form only a rare exception to the general good feeling which ought to characterise the legitimate practitioners of medicine. Even in the case of an erring brother, it is not for any of our body to cast the first stone against him; and in the instance of Mr. Symes, we cannot perceive that he has committed any error.

It is more than six years since we called the attention of our readers to an endeavour to establish a Children's Hospital in London. The experiment seemed to have been maturely considered, and was supported by a goodly array of Medical names. It has been quietly worked in Great Ormond-street since February 1852; with abundant success, as far as the poor are concerned, but with a comparatively slender support from the public. We regret to find that the Dinner in aid of its funds, at which Mr. Dickens is to preside on February 9th, is intended not for the increase of its usefulness only, but even to ensure the existence of the Charity. We must heartily commend the Children's Hospital to the help and good word of all members of our Profession, as an honest endeavour to supply a want which we all are conscious of, and to furnish the student in medicine with opportunities for acquiring a knowledge of an important class of diseases such as no other institution in London affords.

After three weeks' study, the Committee of the General Lying-in Hospital have prepared a reply to Dr. Rigby's letter to the President, and to our own article of the 12th ult. This reply will be found in another column. So far as it affects Dr. Rigby's letter, we shall leave that gentleman to show how far the statements and arguments of the Committee are correct. The only remarks we feel called upon to make are, that our assertion, as to the ventilation having been carried out irregularly since May 1855, is borne out by the fact that Dr. Rigby himself, in order to attempt to reduce the expenditure of coal to the minimum consistent with thorough ventilation, had brought it too low at times, so that the draught of air through the shaft was not kept up. We may add, that the Committee, according to their own letter, appear to be ignorant of the working of the system of ventilation in their own Hospital. The air is obtained from without, at the highest point of the building, and is brought down a shaft to the chamber from whence it is distributed over the building, and any pollution of the air in the chamber by the emanation from drains is purely imaginary. This subject is of such great practical importance, and the facts brought forward by Dr. Rigby are so singularly illustrative of the causes of Hospital mortality, that we trust no personal feeling will check a full discussion and fair examination of the evidence adduced.

At the meeting of the Epidemiological Society last Monday a paper was read on the Cholera in Sunderland, which we

trust will lead to some practical good. The importance of the sanitary inspection of shipping was well brought out by the author, as well as Dr. Waller Jones and Dr. McWilliam, in the discussion which followed the paper. Mr. Spencer Wells then urged the importance of such inspection, especially upon vessels arriving in this country from foreign ports where cholera was epidemic, showing how easy it would be to have buildings in healthy situations on shore, to which patients suffering from, or threatened with, cholera could be removed, and kept from endangering a healthy population; and it was agreed that at the next meeting of Council a motion should be brought forward for an early representation to Government in the name of the Society in favour of such special inspection. We have so often insisted upon the necessity of such a measure, and pointed out the unnecessary danger to which the people of this country are exposed by the apathy of Government, that we trust the Epidemiological Society will act heartily in the cause.

The proposed amalgamation between the Odontological Society and the College of Dentists is likely to be set aside by what appears to us to be a very trivial and unimportant difference. It is proposed that the united body should be recognised hereafter as "*The Institute of British Dentists*;" but to this the College object, and hold to the term *College*, many country members seeming to think that there is some charm or *prestige* in the word *College* which there is not in the word *Institute*. If we are to judge by the French acceptation of the term, this is a great mistake. The other point reminds one of the man and wife who had been married thirty years without children, and separated upon a difference as to the name of a son, should one be born to them. One body proposes that the College of Surgeons should be urged to grant special dental diplomas, but in the event of their refusing to do so that the united body—Institute or College, as the case may be—shall grant the diplomas. "Surely," say certain gentlemen, "the united body are as competent to grant diplomas as the College of Surgeons! We won't ask for diplomas as Surgeons. We don't know whether we shall get them if we do ask, but rather than ask we refuse to amalgamate, and thus unite together in one great body the Dentists of Great Britain." Such conduct is very much to be regretted.

## REVIEWS.

*Correspondence and Statements regarding the Teaching of Clinical Medicine in the University of Edinburgh, etc.* By T. LAYCOCK, M.D., Professor of the Practice of Medicine, etc. 8vo. Pp. 70. Edinburgh: 1858.

We have seldom perused a document which has given us so much pain as the "*Correspondence and Statements*" just published by Dr. Laycock, the Professor of Medicine at the University of Edinburgh.

We have no wish to enter into the details of this entangled skein of bitter, unworthy, and highly unprofessional feeling, still less to pronounce any opinion as to what is right and fair, or what is wrong and unfair in the case; but what we feel bound to notice and deprecate is the *spirit* in which this sad affair has been conducted—the mean quibbling, the continued non-adherence to previous statements, the unworthy subterfuges, and, lastly, the positive deviations from truth and their consequent painful exposure.

We have no personal interest, and are in nowise partisans in this matter; indeed, we look upon the original cause of the dispute as of secondary importance in comparison with the results to which it has given rise. We, in common with the Profession in general, entertain the highest respect for Dr. Christison's great talents and valuable works; but if these statements of Dr. Laycock be correct, (and it is impossible to imagine that he could have deliberately invented

correspondence and statements by wholesale,) what can we say to the painful exposures to which they have given rise?

We will mention but one circumstance which has struck us with peculiar force. The following passage occurs in a letter from Dr. Christison to Mr. Douglas, dated December 1, 1857, and published at page 62 of Dr. Laycock's pamphlet:—

"I hereby declare, therefore, that I heard Mr. Syme read, as the arrangement, acceded to by Drs. Bennett and Laycock for the future teaching of Clinical Medicine, the three short clauses contained in Dr. Laycock's pamphlet, page 27: That Dr. Laycock and Dr. Simpson were both present; that these gentlemen, as well as the other members of the Faculty, concurred in the arrangements."

Yet, at a meeting of the College Committee, Dr. Laycock says—

"Dr. Christison felt obliged to avow that he had not heard Mr. Syme read the three short clauses (*ante*, p. 27)."

Dr. Christison was allowed to withdraw his letter, he says to correct it, but we do not see that the corrections alter the case, which is complicated in the most extraordinary manner by direct assertions and positive contradictions, and we feel bound to ask, Is this the right mode of conducting a discussion or dispute between gentlemen and men of distinguished scientific position? Even supposing, for argument sake, that Dr. Laycock has been unfair and grasping in his demands, and discontented with every equitable arrangement, does this, or anything else, justify such conduct? One of Dr. Laycock's concluding sentences gives a melancholy picture of the spirit in which disputes are carried on in Edinburgh. "It has been my great good fortune, it is true, to be able to rebut these painful attempts to injure me in the estimation of the patrons, the University, and the public, by the publication of documents of which the accuracy is unquestionable; but let it be supposed that I had lost or destroyed the letters in question, or that I had continually to make "corrections," what would then have been my position? I must have been inevitably borne down by hardihood of assertion, and have suffered irretrievable injury to my character and prospects."—p. 69.

Are our professional brethren of Edinburgh always to live in an atmosphere of intrigue and hatred one towards another? We know that there are many bright and honourable examples to the contrary; but it is a fact, no less sad than notorious, that the Edinburgh University has been for years the scene of constant and bitter feuds, not less discreditable to the parties than injurious to the University, and it requires no peculiar foresight to prognosticate that such a state of things must bring ruin upon themselves, and the good old alma mater.

*The Enlarged Prostate, its Pathology and Treatment.* With Observations on the Relation of this Complaint to Stone in the Bladder. By HENRY THOMPSON, F.R.C.S., etc. London: 1857. 8vo, pp. 320.

In this work Mr. Thompson brings before the Profession the conclusions he has arrived at after not less than "seventy original dissections," an extended examination of the metropolitan museums, and considerable clinical experience.

In the first chapter he describes the anatomy of the prostate very fully, giving good grounds for rejecting for the future the term "third" or "middle lobe," and adopting the more correct phrase, "posterior median portion."

In the second chapter the analogy between the enlargements and tumours of the prostate and those of the uterus is discussed. Mr. Thompson lays great stress on the fact that organic muscular fibre constitutes the bulk of both organs, and that tumours of the two organs are identical both in external and histological characters.

The alleged causes of enlargement of the prostate are examined in the third chapter. The views advocated by the author are novel, and demand investigation. He argues that neither inflammation, nor stricture and calculus, nor venous stasis, nor gout, rheumatism, and syphilis, can cause the enlargement. In cases where enlarged prostate occurs in persons who have suffered from any of the preceding affections, he looks upon the relation as merely casual. The frequency of enlarged prostate in gouty patients, however, would lead us to doubt the general correctness of this view. Mr. Thompson does not speak with confidence as to the effect of sexual excesses on the prostate. He insists that prostatic enlargement is "not analogous to glandular hypertrophy, nor to hypertrophy of other muscular organs depending on increased

function," but that enlargements of the prostate and uterus are identical in nature, and probably depend on their common structure. "The origin of hypertrophy being thus attributed to a necessity of structure, no doubt all circumstances which tend to induce active determination of blood to this locality may aid in its development."—P. 65.

In the fourth chapter the symptoms of enlarged prostate are carefully described, from the phenomena first noticed to the last stage; and in the succeeding chapter the effects of the enlargement are described in relation to retention and incontinence of urine.

The sixth chapter, on the diagnosis of prostatic and other obstructions at the neck of the bladder, is full of useful practical hints. In the seventh, we come to the treatment of senile enlargement of the prostate, and the chronic cystitis and irritability of bladder connected with it. The author speaks highly of benzoic acid as a means of "producing acid in the place of alkaline urine," after all other means have failed. In one case he relates he gave it in scruple doses every six hours, dissolved in a drachm and a half of spirits of wine. We have seen similar good effects from much smaller doses than this, viz. five grains three times a day.

As to the treatment directed against the enlargement itself, Mr. Thompson expresses the hope that iodine and bromine may prove to have some remedial power. "The influence of these agents over simple enlargements of the uterus is undoubted, and a certain analogy between uterine and prostatic enlargements has already been pointed out." The hope was confirmed by a visit to Kreuznach, and inquiry into the action of the water there, which is so highly charged with iodine and bromine. The following observations are so good, that we extract them:—

"I am of opinion, then, that it is certainly worth while to attempt the reduction of enlarged prostate, especially if it be an example which is ascertained to constitute a pretty uniform tumour in the rectum. If the patient enjoys a fair share of health, there is nothing to contra-indicate it; the treatment may be pursued without exhausting the constitution, or deranging the digestive functions.

"The plan which I have pursued in a few cases is the following:—

"Tepid hip-baths, daily, of water to which the bitter or mother-lye of the Kreuznach springs has been added, in varied proportions, beginning with half a pint, or pound, according to the form in which it is obtained (see note below (a),) to four gallons of plain water, at a temperature of

(a) "The principal spring at Kreuznach employed for medical purposes is the Elizabeth-Quelle. Its temperature is 54½° Fahr., and it contains about 90 grains of solids in the 16 ounces, with about 5 cubic inches of carbonic acid gas.

"The following is one of the most recent analyses, by Bauer:—

Chloride of sodium . . . . .	72.92
" potassium . . . . .	0.97
" magnesium . . . . .	0.25
" calcium . . . . .	12.98
Carbonate of magnesia . . . . .	1.57
" lime . . . . .	0.27
" iron . . . . .	0.20
Bromide of sodium . . . . .	0.30
Minute quantities of iodine, manganese, and some earthy bases with chlorine . . . . .	1.47

90.93 grs. in 16 oss.

In this form it is administered internally in small quantities.

"But for topical applications, the water of this spring is strengthened in saline constituents by the addition of the mother-lye after the elimination of the chloride of sodium at the Salt Works, which exist on a very large scale close by the town, at other saline springs. This mother-lye, of which the specific gravity is between 1.3 and 1.4, contains no less than between 2000 and 3000 grains of solids in 16 ounces. A late analysis gave the following result:—

"In 16 ounces of the mother-lye there were 2484.16 grains of salts, constituting about a third part of the mixture.

Chloride of calcium . . . . .	1789.97
" sodium . . . . .	226.37
" potassium . . . . .	168.31
" magnesium . . . . .	230.81
" aluminium . . . . .	1.56
" lithium . . . . .	7.95
Bromide of sodium . . . . .	59.14
Iodide of sodium . . . . .	0.05

2484.16 grains.

"This fluid being evaporated, the saline matters have for some time past been imported to this country for medicinal use; but the result is considered somewhat inferior as a therapeutic agent both here and at Kreuznach, to the original mother-lye, while it is certainly somewhat less convenient for use. More recently this has been imported, by Messrs. Schacht, of 38, Houndsditch; from whom my patients have obtained it in any quantity required, at a very reasonable rate."

90° to 94°, or warmer, if preferred; in this the patient should be seated for twenty minutes every morning.

"Local application may be made either by enema or suppository; if by the former method, the following formula may be depended upon as not too irritating to the rectum. It should be retained there as long as the patient can conveniently do so. The best instrument for injecting it is an india-rubber bottle with ivory tube, as the constituents of the Kreuznach water will rapidly injure metallic apparatus.

R. Potass. iodidi, gr. v.

Kreuznacher bitter, ʒij.

Dec. hordei vel lini, ʒiij.

Misce pro enema, quotidie utendum.

"To this a little opium may be added if necessary, in order to enable the bowel to retain it.

"The suppository, which, on the whole, is perhaps more easily administered and borne than the enema, may be used after the following form:—

R. Potass. iodidi, gr. ii.—v.

vel Potass. iodidi.

Potass. bromidi, ʒā, gr. ii.—iii.

Cerati, gr. viii.

Misce, fiat suppositorium.

"This should be employed at the time of going to bed, and may be repeated every night for a considerable period.

"The Kreuznach water itself, from the Elizabeth-Quelle, is now obtainable in this country, but is probably less useful than the bromide and iodide of potassium, given internally. I must confess I am disposed to believe less in the value of internal remedies than in that of the topical means described. At most, I would employ only small doses of the bromide and iodide of potassium conjoined, in some suitable vehicle; these are more likely to be useful, and are much better borne by the stomach than the natural water, with its large proportion of chloride of sodium. From three up to ten grains of the bromide with, at most, one of the iodide, twice a day, is the quantity I have employed. It is scarcely necessary to say that this course must be persevered in for a considerable period of time, during which the dose may be gradually increased.

"Of the application of these irritants in any form or degree to the surface of the sensitive mucous membrane of the urethra I wholly disapprove. Nothing is easier than to pass down to the prostatic part a small portion of ointment impregnated with some chemical agent, and project it into the urethra there. But that it can remain there in any quantity, or for any time, adequate to the absorption of a part of the salt introduced, I do not believe: the greater part, if not the whole, is speedily removed to the bladder, and the utmost which can be expected to result is an amount of irritation corresponding to the quantity of the agent employed, an effect which, in any degree, is positively injurious.

"Now, although I think we may by perseverance in this line of treatment, aided by those other appliances, and by an appropriate regimen, which are necessary, and have been already described, attain some improvement in the condition of the prostate, or, perhaps, be able to retard its increase, I do not think we are warranted in expecting to reduce the bulk of a considerably enlarged prostate of long standing by the means described. They are, however, simple, easily employed, and unattended with any danger to the patient: and they certainly hold out more promise than any other therapeutic agents with which we are acquainted. They can be tried by the patient himself for a considerable period of time (and without perseverance for some few months it would not be desirable to commence their use), with but the occasional superintendence of his medical attendant, when once instructed at the outset. All the advantages which the natural springs possess are now attainable at home, since the treatment, mainly consisting as it does of external applications, is pursued with precisely the same elements as at Kreuznach, in no respect altered by their transmission here; while for internal remedies, the artificial product of the chemist is preferable to the crude salt water of the native springs.

"Under these circumstances I am induced to conclude that we shall act judiciously in advising most patients whose health is good, and in whom the complaint is not considerably advanced, to make trial of the treatment in question."—Pp. 151—154.

It will be observed that Mr. Thompson only speaks of the

effects of this treatment conjecturally. He does not seem to have tried it, but it is certainly worth trial. Our own experience teaches us to believe more in the value of the bromide of potassium administered internally than Mr. Thompson appears to do by the above passage. We have long been in the habit of giving it and the muriated tincture of iron alternately week by week—a week of the bromide and a week of the iron—for several months, and have no doubt whatever that enlarged prostates have diminished very considerably in size under the course. The dose has been from half a drachm to a drachm of the bromide daily, and the same quantity of the iron tincture. Mr. Thompson has contrived a very useful modification of Dr. Arnott's stricture dilator by fluid pressure, with the view of compressing the prostate by dilating the prostatic urethra. The instrument is figured at page 159, and will doubtless come into general use.

The treatment of retention of urine from enlarged prostate.—The enlargement of the prostate from inflammation as distinguished from hypertrophy, are the subjects of two following chapters. The tenth chapter treats on malignant disease of the prostate, which the author shows is almost invariably encephaloid. Tubercular disease and cysts of the prostate fall under review in the next chapter. Tubercle is rare in the prostate, and is almost invariably associated with tuberculous kidney or testicle.

The twelfth chapter on the bar at the neck of the bladder is a very interesting essay on this important subject. The following are the author's conclusions:

"First,—That in the great majority of cases in which there exists an organic obstruction, having more or less the form of a ridge or barrier, situated at the posterior border of the neck of the bladder, this unnatural elevation is constituted by an outgrowth arising from the posterior median portion ("middle lobe") of the prostate.

"Secondly,—That an organic obstruction may exist at the neck of the bladder, when there is no enlargement of the posterior median portion of the prostate.

"Thirdly,—That in this case it most commonly consists of an undue elevation of the uvula, associated with hypertrophy of the muscular elements of the bladder, particularly of the muscles leading from the orifices of the ureters to the urethra—originating in long-continued irritability of the viscus, and generally occasioned by stricture of the urethra, or calculus of the bladder.

"Fourthly,—That much less commonly it consists of a fold of mucous membrane and submucous tissue drawn upwards by enlarged lateral lobes of the prostate, the posterior median portion being slightly, if at all, affected.

"Fifthly,—That, very rarely, such a barrier exists in the absence of any known cause for its formation, in which case it appears to consist, as in the preceding, of a simple elevation or fold of the tissues which form the posterior border of the urethro-vesical orifice, no enlargement of the prostate being present."—Pp. 250, 251.

Our limits forbid us following Mr. Thompson through what will probably be considered by his readers the most interesting chapter in his book—the concluding observations on the relation between enlarged prostate and stone in the bladder, and the best mode of applying lithotripsy for the removal of the stone. This chapter—like the other portions of the book, and everything else which Mr. Thompson has written—shows careful research, much thought, power of accurate observation, great practical tact, and sound judgment. His book should be read by every surgeon who treats or hopes to treat cases of diseased prostate.

A BAD END.—On Saturday, a coroner's jury assembled at the residence of a lady, No. 2, Mortimer-street, Cavendish-square, to inquire into the death of Mr. C. Brook Hunter, aged 28. In July last deceased, who was a Medical student, arrived in town from Norfolk, for the purpose of passing his examination; instead of which, however, it is said, he plunged into the follies and extravagance of the metropolis, in which career he continued up to the time of his decease. On a friend calling upon him, and going to his room, deceased was found in bed dead and cold, with an empty phial which had contained laudanum by his side.—Verdict, "That deceased destroyed himself by taking laudanum, but what state of mind he was in at the time there was no evidence to show."

## REPORT ON CROSS-PRESENTATIONS.

By PROFESSOR SPAETH.

AMONG the 12, 523 births which came under Professor Spaeth's observation while he held the post of assistant accoucheur at the General Hospital, Vienna, 93 cross-births occurred. Cross-presentations were also, besides these, very frequently diagnosed in pregnant women with exactitude, which on the commencement of labour were converted spontaneously into presentations of the long axis of the body. In primary cross-presentations, i.e. before the rupture of the presented, although in some instances the back or the abdomen membranes, the lateral portion of the child's body usually was found turned towards the os uteri. In the latter cases the extremities were generally found presenting, and in one instance, both the lower extremities and one of the upper were felt within the os, while the axis of the child's trunk lay completely parallel to the transverse diameter of the uterus. In secondary cross-presentations, i.e. the waters being discharged, the foetus, when normally developed, always presented with its shoulder; of 56 exactly indicated cases, in which the lateral part of the body or the shoulder presented, in 39 the back of the child was placed forward (24 times with its pelvic end towards the left-side, and 15 times towards the right side), and in 17 it was placed backwards (11 times with its pelvic end to the left, and 6 times to the right side).

The following may be enumerated as causes of cross-presentations.

1. *Twin births.* Among the 157 instances of those that occurred, the second child was found in the cross-position 13 times—therefore 1 in 12. The first child was always found in the long presentation.
2. *Maceration of the child.* Among 176 macerated children, 7, i.e. 1 in 25, presented cross-wise.
3. *Premature birth.* Of 656 children, born between the fifth and ninth month, and not in a macerated condition, 16 presented cross-wise—1 in 40.
4. *Placenta prævia.* In 13 cases of this, cross-presentation occurred 3 times. In these 3 cases the placenta was always so placed as to entirely cover the os uteri, while this was only found to be the case in 1 out of the other 10 cases.
5. *Relaxation of the walls of the uterus.* Scanzoni correctly considers unusual relaxation of the parietes of the uterus as one of the most essential circumstances in the production of cross-positions; and it is on this ground that the more frequent occurrence of the position in women who have borne several children is to be explained. Thus of the 93 cases in question, only 20, or of 52 cases not included in the above categories only 10, were primiparæ. Moreover, in the bulk of the great number of cross-positions ascertained to exist during pregnancy, but which were spontaneously converted at the onset of labour into long-presentations, presented this condition of relaxation, the rectification taking place apparently because the contractions of commencing labour obliged the hitherto relaxed organ to assume its natural form, thereby removing one cause of the faulty position.
6. *Abundant liq. amnii.* This was also often observed in pregnant women exhibiting cross-position. With the great mobility of the foetus which exists in such cases, it is quite a matter of chance whether the foetus during labour is not found in the cross-position. Among the 93 cases such excess of fluid was observed in 10, and certainly occurred yet oftener, in certain of the cases brought to the hospital only after the membranes were broken.
7. *The pear-shaped shape of the uterus, i.e. a slight degree of the uterus bicornis.* This was observed in one case only, but this was an example of the recurrence of the position in three pregnancies. Braun relates a similar case; and there is hardly any doubt that this deformity of the uterus, which is as perceptible after the birth of the child as before its expulsion, is a cause of habitual cross-position.
8. *Eventration of the abdominal viscera* was observed in 2 cases by the author, once at the hospital and once in private practice, the child being at about the 7th month in each case.

The course and treatment of the 93 cases were as follow:—

A. *Spontaneous Turning.*—This occurred in one case, that of a woman, aged 24, pregnant for the second time. At 8 a.m., 11th June, the waters were unexpectedly discharged.

The os uteri was found relaxed, and the ribs of the child could be plainly felt through it. On external examination, the back of the child was found to be turned forwards, its pelvic extremity lying nearer to the entrance of the pelvis than its head, which lay towards the right side. The uterus was soft, and slight contractions only occurred at long intervals. The patient was kept lying in bed on her left side, and strong pains only came on in the afternoon of the 13th. Under their influence, the pelvic end of the fetus passed spontaneously through the os, the uterus assuming its normal longish-round form. At 5 p.m. the living child was born with ease.

B. *Spontaneous Delivery in Shoulder Presentation.*—This occurred in five instances, and these consisted in a foetus of five months, one of six, two of seven months, and one at full time. The six months' foetus and one of those at seven months were in a macerated condition, and the others died during labour. The first of these cases, on account of the smallness of the child, was left to itself, while the others only came under observation after repeated unsuccessful efforts at turning had been made. The mechanism was the same in all these cases. The shoulder, under the influence of strong pains, was gradually pressed deeper into the pelvis, while the head advanced more and more forwards from the side of the mother towards which it was turned, until at last it lay exactly over the symphysis pubis. At the same time the trunk moved towards the sacro-iliac symphysis on its side, and was, through the pressure excited upon the buttocks by the fundus uteri, forced down the sacral hollow behind the head, so that first the presenting shoulder, then the under part of the thorax, the buttocks, and the feet passed out, and then finally the head was expelled. The complete extrusion of the shoulder, while the head remained at the entrance of the pelvis, was, however, only rendered possible by means of excessive extension of the neck. Two of the mothers suffered from slight peritonitis, but all recovered.

C. *Turning.*—This was effected in 86 cases.

a. *Cephalic Turning.*—Besides the very numerous cases of oblique cranial position in which the head deviating to one side or the other, was directed by manipulation into the pelvic entry, this procedure was put into force in six instances of cross-presentation, the manipulation being external in 2, and internal in 4 of the cases. In the two former, the membranes were as yet unruptured, the uterine walls were relaxed, and the pains infrequent, while the child was sufficiently moveable, without the liq. amnii being in excessive quantity. The woman having been laid on her back, one hand was placed above the child's head and the other beneath its pelvis, and by simultaneous pressure the one was directed towards the aperture of the pelvis and the other towards the fundus uteri. As soon as the head had somewhat approached the aperture, its further progress was much favoured by laying the woman upon the side corresponding to that towards which it had lain. The children in both these cases were born alive. In the four cases treated by internal manipulation, the membranes were still entire, and the hand corresponding to the side on which the head lay was, during an interval of the pains, passed sufficiently high between the uterine wall and the head to enable it to seize the head and draw it towards the pelvic aperture. This manoeuvre was assisted by the other hand, placed externally, either pushing the buttocks up towards the fundus, or aiding in thrusting the head downwards. All the children were born living.

b. *Turning by the Buttocks* was executed by external manipulation in one instance, the child being born living.

c. *Turning by one or both Feet.*—This was performed 78 times under the following different circumstances:—

1. *Prior to the rupture of the membranes* in 39, ten being examples of twin-births. The author places the woman on her back, with the pelvis somewhat raised, and introduces the hand corresponding to the side to which the child's feet are directed, when this can be ascertained. But before the waters are discharged it is indifferent to an experienced practitioner which hand he employs. With the exception of two cases, in which hæmorrhage from placenta prævia occurred, full dilatation of the os uteri was always waited for; and the membranes were preserved entire, when possible, until the hand had reached the spot where the feet were expected to be found. They were then broken, and where rapid delivery was required, as in placenta prævia, both feet were brought

down, otherwise only one. In the latter case the labour was then left, for self-completion, unless the state of the pulsation of the funis or other dangerous circumstances called for haste. In all cases, however, the delivery of the head had to be assisted, viz. in 37 by manual interference, (a modification of Smellie's method) and in 2 by the forceps. In the 37 cases, there were born 28 living (3 being still-born but soon restored), 4 dead and 5 macerated children. Of the 4 dead children, in 2 the birth had been preceded and accompanied by severe hæmorrhage, in one there was eventration, and one had to be extracted from want of pains. Of the two children delivered by the forceps one was born alive and the other in a macerated condition. As unfavourable complications, there were two instances of narrow pelvis and three of placenta prævia.

2. *After the discharge of the liquor amnii.*—These cases were also thirty-nine in number. The operation was rendered much easier by choosing the hand which corresponds to the side of the mother to which the feet are directed, and which when the waters are discharged could always be ascertained. In part of the cases it was introduced in the German method, by passing its volar surface over the abdomen of the child to the feet. In others, the French method was adapted, by which the presenting lateral parts are pushed farther away, and the hands carried over the buttocks to the feet. From the former none of the ill effects said to result from compression of the funis or abdomen were found to arise. In difficult cases great are the effects of a proper position of the woman and choice of the hand, together with carefulness and steadiness in its introduction. By observation of these points the experienced accoucheur will often succeed after many failures on the part of others. Still, there are cases in which the observation of every precaution is not followed by success, as when the uterus becomes so closely bound round the child by continuous, tetanic contraction, as to forbid the passage even of a quill between them. There are cases, too, in which vain attempts at turning have so excited the uterus as to have aroused the most vehement pains, which follow one after the other in rapid succession. Who, in attempting, under such circumstances, to turn the fast-locked fœtus, would not have the terror of rupture of the uterus before his eyes! It is in such cases that chloroform, or a mixture of chloroform and ether, is of unequalled utility, rectification often becoming possible during anaesthesia, when decapitation would be otherwise unavoidable.

1. Among these 39 cases of secondary cross-positions there were 19 cases in which turning took place immediately after the rupture of the membranes. Of these, (1.) There were 8 accompanied by unfavourable complications, viz. 2 with hæmorrhage, one child living, the other dying; 3 with prolapse of the funis, 2 living and 1 dying; 1 with the induction of premature labour at the end of the 8th month, the child dying; 1 with very rigid genitals in a primipara, the child living; and 1 with a large headed child, which lived. (2.) The other 8 cases were uncomplicated, and all the children were born living. Altogether in the 19 cases, 10 of the children were born living, 4 came still-born, one of these dying, and 2 were born dead. (b.) Cases in which turning was performed within the first half hour after the rupture of the membranes. These were six in number, in one of which only the child died. (c) Cases in which it took place at a later period, either because the patient came late under observation, or that the waters were discharged prior to the commencement of labour. Of these 7 cases, turning was executed in 4 in one hour, in 1 two hours, in 1 five hours, and in 1 twelve hours afterwards. Two of the children died. (d) In 7 cases the membranes were ruptured before the commencement of the pains. In these cases turning was accomplished after 9, 10, 23, 29, 37, and 64 hours, and in one case the exact time was not known, the child being dead when the patient was admitted. Among all these cases turning was not attended with any difficulty except in the first one. The cases under (c) and (d) sufficiently prove that nature usually leaves space enough after the discharge of the waters to admit of turning with success and without much difficulty, providing always that unsuccessful attempts have not excited the impetuous action of the uterus, which leads either to the death of the fœtus, or renders turning exceedingly difficult or impossible. (e) Cases in which turning was accomplished after prior unsuccessful efforts. Of these there were three, and the author relates two others which occurred in his private prac-

tice. Chloroform was employed in three of these, and turning would probably have been impossible without its aid. All the children were dead.

Summing up the results of the 85 cross-presentations treated by turning, we find that 66 children were born living (of these 9 were still-born, 8 recovering, and 1 dying), 13 dead, and 6 in a macerated state. Separating the macerated children, as already dead before the commencement of labour, the proportion of dead to the living children was 1 in 5. Of the mothers, 69 were in good health, 6 recovered after short illnesses, 1 was transferred to the hospital on account of metastasis, and 9 died. It is to be remarked, however, that the confinement of some of the fatal cases took place at a time when a bad form of puerperal disease prevailed. Of the entire number of 12,523 confinements which furnished these 85 cases, 546 women died of puerperal disease, and 73 were removed to the hospital on account of metastasis, eclampsia, &c. Hence the proportion of mortality in the whole was at least 1 in 22.

D. *Decapitation.*—This was performed in two instances, which are related, the children being dead, and the shoulder being so much forced down, and the child so closely compressed by the uterus as to render attempts at turning dangerous. Braun's modification of Smellie's hook was employed.—*Wien Wochenschrift.* 1857. Nos. 8, 9, 10.

### ON LESIONS OF THE EPIGLOTTIS.

By Professor HORACE GREEN.

The following are the conclusions of a paper recently read before the New York Academy of Medicine:—1. The epiglottic cartilage is subject to serious alterations of structure, which, it is believed, have not received that attention in practical medicine which their importance demands. These lesions, which are ordinarily the results of inflammation, are erosions of the mucous membrane of the epiglottis, ulceration of the membrane and its glands, and œdema of its areolar tissue. Both erosions and ulcerations, although occasionally found associated with tuberculosis, are often found to exist as primary disease, being the antecedent, and, in many instances, the exciting cause of other grave affections. 3. Erosions occur much more frequently than ulcerations, and differ from the latter in being much more superficial, as they are confined to the mucous membrane, and ordinarily to its epithelial layer. 4. Primary ulcerations of the epiglottis are alterations of structure, differing essentially from erosions. They originate apparently in the follicles of the mucous membrane, which soften and ulcerate, and, penetrating the fibro-cartilage, ultimately destroy a portion of the epiglottis, and, if not arrested, prove the cause of much more serious disease. 5. (Edema of this cartilage is a lesion of somewhat frequent occurrence, the result, ordinarily, of catarrhal inflammation. It is attended generally with loss of voice and difficulty of deglutition, and is occasionally complicated with ulcerations of the cartilage, by which, in some instances, the epiglottis has been completely destroyed. 6. The epiglottis, which is almost insensible in its normal state, becomes when diseased frequently the source of great irritation to the more sensitive adjacent parts. The presence of this cartilage is not indispensably necessary to secure deglutition. It is necessary, however, to render this act perfect. But its most important function is to cover over and protect that exquisitely sensitive portion of mucous membrane which occupies the supra-glottal space, and which is the true sentinel at the glottic opening. 7. But the most important practical conclusion found in these propositions is, that some of the lesions which have now been described are often, it is believed, not only among the earliest manifestations of thoracic disease, but are themselves, in many instances, the true exciting causes of these affections; and, furthermore, this postulate once established, that we have it in our power, by timely topical medication, to positively arrest cases of disease which otherwise would, and in many instances do, terminate fatally.—*New York Journal*, November, p. 348.

### EXCERPTA MINORA.

*Treatment of Frostbite by the Esquimaux.*—An Esquimaux had his leg frozen above the knee, stiff, colourless, and to all appearance lifeless. He was placed in a snow-house, at a temperature of 20° below zero. The parts were bathed with ice-cold water for about two hours, and then enveloped in furs for three or four hours. Then frictions were used, first

with the feathery side of a bird-skin, then with snow, alternately wrapping the limb in furs, and rubbing it for nearly twenty-four hours. It was next carefully wrapped up, and the temperature of the snow-house raised by lamps above zero. On the third day the patient was taken to his house (where there is often a temperature of 70° or 80°), and in seventy hours he was walking about, with only a slight frost-bite on one of his toes.

*Dr. Hays in Boston Journal*, vol. lvii. p. 48.

**Treatment of Acute Rheumatism.**—Dr. Gordon states that after trying the various remedies for this disease, he finds the following treatment that which is best adapted for preventing its passing into a lingering state:—"After having procured free evacuation by means of senna and salts, I begin the administration of equal parts of vin. colch. and spt. tereb. in doses of 10 drops every two or three hours. After a day or two, I give in connexion with these (only at different intervals, say of five hours each), tr. ferri chlor. 10 drops, using as much opium as may be necessary to quiet pain. I also allow a free use of infusion of coffee, of average strength. If the patient's appetite remain I allow a moderate use of his usual food at the customary intervals."

*Boston Journal*, vol. lvii. p. 70.

**Chloroform as an Antidote to Strychnia.**—A statement in the American journals having come under the notice of the Austrian Minister of the Interior, to the effect that chloroform acted as an effectual antidote to strychnia, he directed Professor Pilwax, of the Veterinary Institute, to investigate the subject. Accordingly, four dogs were poisoned by strychnia, and when the symptoms had become obviously developed, they were submitted to the influence of chloroform, and the results proved that the chloroform was worthless as an antidote.—*Wien Wochenschrift*, 1857, Nos. 6, 7.

**Singular Case of Triplets.**—Dr. Macgregor relates that, on the 10th of August, 1856, Mrs. G. was delivered of a still-born child; twenty-one days afterwards she gave birth to a second; and the same length of time thereafter to a third. The last two lived about six hours each. The mother is doing well, and is again pregnant.—*Boston Journal*, vol. lvii. p. 128.

**Nitrate of Silver in Asthma.**—Dr. Bowditch stated, at the Boston Medical Society, that he had found the application of the solution of the nitrate to the larynx, as suggested by Dr. H. Green, of marked utility in this distressing affection. He mentioned also, as an important practical point, that if the solution be applied immediately after a full inspiration, and just at the commencement of expiration, the latter being performed slowly, little or no inconvenience is produced. Dr. Jackson also related a case in which this application had proved of decided efficacy.—*Boston Journal*, vol. lvii. p. 159.

## FOREIGN CORRESPONDENCE.

### FRANCE.

PARIS, January 3, 1858.

Is it necessary to employ any mode of treatment in cases of cephalhematoma? This is a question which has been debated lately at the Société de Chirurgie. M. Guersant thought it was well to give issue to the blood; Chassaignac and Cozeaux stated that they had always seen the disease come spontaneously to a cure. Giraldès admits the constancy of spontaneous cures, but he thinks that the patients get rid of the affection quicker after frequently repeated punctures with a cataract needle.

In a discussion, at the Société de Chirurgie, on the chances of reproduction of cancer, M. Cloquet mentioned the curious case of a woman who, during twenty-two years, had been operated fifteen times for a cancer which had originated on the left cheek. There was a long cicatrix extending from the cheek, along the left face and neck, towards the left mamma. For a year there had been no re-appearance of the disease, but it came again a short time before M. Cloquet saw the patient, and he extirpated the tumour. The cicatrization was rapid and easy, and six months after there had been no return of the affection.

Three interesting cases of fracture have been reported at the Société de Chirurgie, by Baron Larrey, to prove the

facility of the production of fractures in paralysed limbs. In one of the cases there was incomplete paraplegia of the lower limbs, with increased sensibility. During a moment of great suffering the patient tried to put one of his legs upon the other, while he pressed upon the thigh with his hands, and the femur broke at about the middle of its length. Although simple the fracture was very long in being cured, and the patient died from the progress of his paralysis. In a second case there was also paraplegia besides amaurosis. While making an effort to put on a boot the patient (who was only thirty years old) broke the femur in its lower part. The fracture was complicated with a laceration of the skin, through which the upper fragment of the broken bone protruded. The synovial membrane of the knee-joint had been wounded, and there was blood effused in the cavity of the joint. Spasmodic movements prevented the contact of the two fragments, but nevertheless consolidation took place irregularly. After various complications, however, the patient died. In a third case there was also incomplete paraplegia, with exaltation of sensibility, in an officer forty years old. During an effort to take off a boot the patient broke his thigh-bone. The fracture was at the inferior part of the bone, simple, and a little oblique. It has not yet been consolidated, although it took place more than ten months ago.

The annual distribution of prizes has taken place at the Académie de Médecine. A prize on nervous vertigo was awarded to M. Max Simon; another prize, on sudden death in the puerperal state, was awarded to Dr. Mordret; a third prize, on the saline mineral waters, was given to a distinguished surgeon, M. Petrequin, of Lyons, and to a chemist, M. Socquet. Besides, the Academy has awarded several prizes and lower rewards or medals for services rendered by Physicians attached to vaccination-offices, to mineral springs establishments, etc. The award of the great prize of 12,000 francs (£480), is postponed to the next year. It is on the best treatment of stricture of the urethra. The Academy has received papers from twenty-two competitors.

We are surprised that British Physicians or Surgeons do not compete for the prizes of the Académie de Médecine. Every body in the world may compete for them. It is necessary only to write in French or in Latin. The papers with a motto and a sealed letter, containing the name and address of the author, must be sent to the Academy before the first of March. The questions proposed are the following:—Prize of the Academy, "History of the application of the microscope to the study of pathological anatomy, to the diagnosis and the treatment of diseases; point out the services that this instrument may have rendered to medicine, and those that it probably may still render, and give a warning of the errors to which it may lead." This prize will be of 1000 francs (£40). Papers to be sent before the first of March, 1858. Baron Portal's prize, on pathological anatomy of cysts of the ovary, 600 francs (£25). Civrieux's prize, on the differences between neuralgia and neuritis, not only according to recorded facts, but after experiments on the inflammation of nerves, 1500 francs (£60). Capuron's prize, on the death of the child during delivery, 1000 francs (£40). Barbier's prize, on the means of treatment of so-called incurable diseases, such as hydrophobia, cancer, epilepsy, scrofula, typhus, cholera, etc., 2000 francs (£80). For all these prizes the paper must reach the Academy before the 1st of March, 1858. For the following prizes the papers shall have to reach it before the 1st of March, 1859. The Academy's prize, on the therapeutical action of perchloride of iron, internally and externally, 1000 francs (£40). Portal's prize—pathological anatomy of strangulated hernia, 1000 francs (£40). Civrieux's prize, on nervous affections due to a syphilitic diathesis, 1500 francs (£60). Capuron's prize, on the retroversion of the uterus during pregnancy, 1000 francs (£40).

M. Collongues wrote last year to the Académie des Sciences, that there is a peculiar sound originating from all parts of the body during life. Now he writes again to propose to make use of the absence of this sound as a sign of death. By auscultation immediately after death the sound is distinctly heard; it lasts from five to ten or even fifteen hours, and its diminution is gradual, the parts most distant from the heart being the first in which it disappears. According to M. Collongues, the complete absence of the sound all over the body is a positive sign of death. In an am-

puted limb the sound exists for a few minutes, and disappears first in the parts most distant from the trunk.

Dr. Brown-Séquard presented lately a paper to the Académie des Sciences, in which he tried to prove the two following propositions: 1st. That arterial or venous blood, from an animal of any one of the four classes of Vertebrata, containing oxygen in a sufficient quantity to be scarlet, may be injected, without danger, into the veins of a vertebrate animal of any one of the four classes, provided that the amount of injected blood be not too considerable. 2nd. Arterial or venous blood of any vertebrate animal, being sufficiently rich in carbonic acid to be almost black (noirâtre) cannot be injected in the veins of a warm-blooded animal, without producing phenomena of asphyxia and most frequently death, after violent convulsions, provided that the quantity of injected blood be not below one five-hundredth of the weight of the animal, and also that the injection be made not too slowly. Dr. Brown-Séquard states that he has transfused in the jugular vein of dogs without any ill effect, blood of rabbits, guinea-pigs, cats, cocks, hens, pigeons, ducks, turtles and tortoises, frogs and eels. In rabbits and birds he has also transfused blood of other animals without any marked bad effect. He attributes chiefly to carbonic acid the phenomena which had been considered as due to differences in the blood of various species. In many communications to the Société de Biologie the same physiologist has related facts to prove that in the experiments of Blundell, of Dieffenbach, and of Prevost and Dumas, there were many causes of failure unknown to these experimenters, which have prevented them from re-establishing life permanently in dogs bled to death and transfused with blood from animals of another species. These causes of failure were, 1st, that too much blood was transfused at once—2nd, that the blood was not fresh—3d, that it did not contain oxygen enough, and contained too much carbonic acid. Dr. Brown-Séquard has ascertained that even the blood of birds, defibrinated and rich in oxygen, has been able to reestablish full and durable life in dogs, weighing from fifteen to twenty pounds, and having lost more than sixteen ounces of arterial blood, i. e. more blood than the dogs of Blundell had lost. From thirty to forty-eight grammes of bird's blood (one to one-and-a-half ounce) have been sufficient in many cases to restore full life.

## GENERAL CORRESPONDENCE.

### VENTILATION AND MORTALITY AT THE GENERAL LYING-IN HOSPITAL.

[To the Editor of the Medical Times and Gazette.]

SIR,—I am directed by the Committee of the General Lying-in Hospital, to forward to you the following remarks in reply to an attack made on them by Dr. Rigby, in a letter addressed to Lord Galloway, and published and commented on by you in your Journal of the 12th Dec. last.

Whatever necessity there may be in the case of other Hospitals for maintaining intelligent Medical authority, and checking ignorant lay interference, by giving to Medical officers full power over their internal arrangements, in the case of the General Lying-in Hospital there needs no change, for its Medical officers are in practice members of the Committee of management, and their advice has invariably been followed. In regard to Dr. Reid's ventilation, Dr. Rigby unfortunately differed from his colleagues Sir C. Locock, Dr. Cape, the late Dr. James Reid, of Brook-street, Grosvenor-square, and Dr. Hutton; but the Committee have felt themselves bound to follow the opinion of the majority of their Medical staff, which was in concurrence with their own.

The vote of censure complained of by Dr. Rigby was passed, not because he had called in Dr. Odling, but because he had done so without the slightest communication with the Committee or with any one of his colleagues, the Medical Officers of the Hospital.

Dr. Rigby, in his letter to Lord Galloway, alleges that after the opening of the Hospital in April, 1842, by the determined opposition of the present matron and nurses under her, the ventilation was rendered worse than useless, the valves were regularly closed the moment his back was

turned, and from April, 1842, to March, 1843, inclusive, nineteen women died; that the following April, two of his own pupils from St. Bartholomew's became House Surgeons, and resolutely carried the ventilation into full activity, and the mortality instantly ceased. The Committee regret that Dr. Rigby should pertinaciously repeat statements so utterly unfounded and so often refuted.

In the first place, the mortality of 1842-3, though accurately stated as to numbers, is most unfairly represented as spread over a year, whereas out of the nineteen deaths, seventeen occurred in four consecutive months, from November, 1842, to February, 1843, inclusive, during which time there were only eighty-eight confinements, giving a rate of mortality under Dr. Reid's system, of about one in five. In the next place it appears, from a long report of Dr. Reid, dated 21st February, 1843, that he attributed the mortality to other causes, and not to defective ventilation, while Dr. Rigby himself, in a letter dated 14th February, 1843, entered on the minutes, stated that the "ventilation of the wards and the purity of the air was quite satisfactory;" and in another letter, dated the 26th February, 1843, he attributed the outbreak of puerperal fever to the closing of the valves of the upper back ward during one evening, but in neither letter does he allude to any systematic closing of the valves by the nurses. Lastly, Dr. Rigby now represents that the cessation of the mortality followed instantly on the arrival, and was caused by the exertions of his two pupils, who were appointed in the month of April, whereas the excessive mortality had ceased by the end of the previous February, there being but one death in March, although the valves, according to Dr. Rigby, were still closed by the perversity of the matron. As these gentlemen remained but three months, their exertions could have contributed as little to the continued salubrity of the Hospital, as their advent to the cessation of the epidemic.

In 1850 the ventilation was stopped by a resolution of the Committee, but in May, 1856, it was again put in operation, on the motion of Dr. Rigby, seconded by Mr. Grissell. In June Dr. Rigby reported the ventilation to be working satisfactorily, but in the twelve months following there were sixteen deaths, eleven of which occurred in the first six months, during which time there were 169 confinements. This fact is passed over without comment by Dr. Rigby, perhaps because the facts are too recent to admit of misapprehension, whilst in your comments it is assumed that the ventilation since May 1856 has been carried on so irregularly, that no definite conclusion can be arrived at, though you wholly omit to give any reason for this assertion. The Committee, however, take a very different view of the matter, and are of opinion, that taken in conjunction with the occurrences of 1842-43 the mortality of 1856-6 demonstrates the inefficacy of Dr. Reid's system to prevent the occurrence or control the duration of epidemics, and they feel themselves to have been fully justified in discontinuing a system which in their own case has twice signally failed, and has, as they are informed, been discarded by other hospitals and public institutions as useless or prejudicial.

It is to be remarked that however good in theory Dr. Reid's system may be, it is difficult to work satisfactorily, and must under certain circumstances be actually prejudicial. In theory no air is to be admitted into the wards except through the fresh-air chamber, but in practice the air is drawn in from the passages and basement. If then miasma existed about the drains, as there is every reason to suppose they did in 1843 and 1855, Dr. Reid's system must have acted as a positive disseminator of poison.

In conclusion, the Committee have to remark upon the extreme unfairness of selecting one member of the Committee and one officer of the institution for personal animadversion. It is ridiculous to suppose that the Matron's opinion of the ventilation could weigh with the Committee against the opinion of the Medical officers, though the mode of expressing that opinion may have offended Dr. Rigby. Mr. Grissell was not present at the meeting in 1850, when it was resolved that the ventilation should be discontinued, and he actually in 1855 seconded Dr. Rigby's motion for its resumption. As regards the hole in the ventilating shaft, Mr. Grissell, in common with the rest of the Committee, did not expect any good result from it; but, as it was recommended by Mr. Weeks, a professional man who had been consulted on the subject, and could at any time be easily stopped up again, it

was resolved by the Committee to make the experiment, and during the summer months it was found to work satisfactorily. But on this, as on every other detail of management, the responsibility must fall on all the members of the Committee, and cannot be thrown on the shoulders of one individual.

I am, &c.

THOS. BEN. J. SMITH,

Secretary to the Hospital.

1, Frederick's-place, Old Jewry, Jan. 4, 1858.

### MEDICAL CHARITIES.

[To the Editor of the Medical Times and Gazette.]

SIR,—As you have considered worthy of notice the remarkable discoveries made by a contemporary from the statistics of our Medical Charities, allow me to add a word on the subject. That long array of figures representing the amount of relief afforded by the different Medical Institutions (the higher numbers of which stand for the cures), are, I believe, placed before an enlightened public with one view alone—to indicate the good that is done, and stimulate subscription; and therefore for one of ourselves to draw from such statistics any scientific inference, exhibits either extreme *naïveté* or some occult design. The two main conclusions are palpably absurd,—the one having reference to the unhealthy condition of London, the other to the expense attending the cure of individual patients. Now, as you justly observe, nothing can be more fallacious than these statistics: for whereas at one institution each out-patient counts simply as one, at another establishment he is reckoned to be as many persons as there are months of his attendance; and at a third place the same individual would swell into as many men as there are numbers of times in which he presents his bottle for medicine. The figures, then, are arbitrarily made, and any other set would do equally well. How otherwise can it be explained that an institution newly founded, near a certain railway station, has relieved during the year as many patients as the largest hospitals in the Metropolis? Of course, from such statistics the method of arriving at the expense attending the cure of patients must be in the highest degree erroneous. But the simple process appears to be this: the revenue of a large Hospital is taken, and divided by the number of patients on the books of the institution (no regard being had for the thousands who seek temporary relief), and the result obtained is compared with that which is got by dividing the subscriptions of a small establishment by the number of persons who daily enter its doors. No notice is taken of the different appropriation of the funds, of the number of servants employed in managing the estate in the one case, nor the annuities to old officers, the maintenance of a paid chaplain, etc., and many other items of expense, of which the smaller institutions know nothing.

To come, however, to the main purpose of this letter: if the statistics of a Medical charity be taken ever so fairly and carefully, the number of so-called cures is not a measure of the utility of that charity, but rather the number of deaths. This, at first sight, may appear anomalous or simply ridiculous, but it can be proved in many ways. In the first place, although the object in parading before the public a long list of cures, is for the purpose of exemplifying the good of the institution, and its very successful mode of treatment, yet all Medical men must know that the inference which they wish the public to draw is an erroneous one; they must know that although one practitioner may excel another in the treatment of an individual case, yet that in the long run, in a large number of cases, there is no difference in the result between them: associated together, as are the physicians and surgeons of this metropolis, and the free intercourse that is going on between them by means of Societies and a Medical press, there cannot be any great difference in the result of their treatment—the fact that there is not is easily capable of proof. If then, the number of cases styled *cured* depends upon the mere arbitrary statement of the Secretary, and the proportion of real cures is the same in all Medical charities, how can the relative value of these charities be known?—only by the severity of the cases admitted, and this again by the number of deaths. For the deaths bearing no reference to the skill of the doctor, illustrate the severity of the cases admitted, and the necessities of the neighbourhood

where such institution exists. Is it not clear that if an hospital be placed in a thickly crowded poor locality, where the worst cases of disease are always admitted, that the mortality will be greater than in one situated in an aristocratic neighbourhood, where there is less poverty, and where disease is less rife? Ought the latter to receive more support, because its proportion of cures is greater than in the first-named institution?

I believe, then, if the hospitals be taken one by one, and the number of deaths be ascertained in every one (except of course special hospitals, as for eye, skin, &c.) a correct measure of the utility of each will be found. I do not say, parade this apparently anomalous fact before the public, but do not let us, on the other hand, pamper to public ignorance by presenting statistics in their present shape. As a consequence of so doing, I may mention the case of a gentleman who is a governor of a large hospital, and at the same time of a neighbouring dispensary, and at the anniversaries of the latter he is invariably overcome by the statistics, (the few deaths and the overwhelming number of cures), and his statement is, that he supposes the hospital is useful for accidents, but that it is very clear the dispensary is doing more good with only a fraction of the expense.

I might mention, too, the amount of good that is done among the *relieved* patients, and as an instance, cite the case of a man who, suffering from chronic laryngitis, undertakes a journey in cold weather; his breathing becomes worse and worse until he falls in the street: he is taken to a neighbouring hospital, but respiration has altogether ceased; tracheotomy is performed, and he is once more restored to life: he leaves the hospital with a tube in his throat, and the case is placed among the *relieved*. I have also seen a number of patients taken into a large hospital when there was not a possibility of curing one, but their necessities for relief were most urgent.

Do not let us, Sir, with these facts before us, commit the disgraceful act of strengthening the public ignorance with reference to all matters connected with the Profession, and pandering to their prejudices for our own individual purposes.

Jan. 5, 1858.

I am, &c.

M. D.

### ON THE ACTION OF THE VALVES OF THE HEART

[To the Editor of the Medical Times and Gazette.]

SIR,—Your number of the 26th of December last reports some experiments by Dr. Halford on the action of the valves of the heart. With deference to the writer of that report, and without at all wishing to impeach the accuracy of Dr. Halford's researches, I must beg to demur to the opinions it represents as "usually received," and as now corrected by Dr. Halford.

It has been known and taught for the last ten years by various manuals and teachers of physiology—I can speak for at least one of each—that the closure of these valves required no muscular contraction, but was a passive ("dead") effect, demanding nothing more than the introduction of liquid into the cavities they respectively close, and the sanity or continuity of their tissue. Fick proved—I believe about ten or twelve years ago—that the proper course of the blood, and the proper action of these valves, could be imitated in the dead heart; and in doing so, proved little more than what any one practically acquainted with physics might have predicated.

In like manner, the injection of liquid proposed by Dr. Halford as a test of the efficiency of diseased valves, has been already practised by me for a space of time nearly as long. Indeed, during the last five or six years, a series of resident Medical officers at the Royal Free Hospital have seen me apply this test, and could speak (if need were) for its facility and completeness. And in the year 1854, in bringing some diseased specimens thus examined before the Pathological Society, I took occasion to describe the plan I habitually adopted, and to recommend it to their notice.

In respect to the details of this plan, I need only repeat, that, in the dead-house, the stop-cock of an ordinary tap of water is often the readiest and easiest way of applying it. If the auriculo-ventricular and semilunar valves are both to be examined, it is best to begin with the former. Cutting off the apex of the ventricle, a small (preferably conical) tube or tap

is passed into the narrow aperture, into firm contact with its muscular sides, and water then gently injected into the ventricle, while the aorta is closed or tied. The injection of the aorta is even more easily managed. The inspection of the semilunar or auriculo-ventricular valves, is of course facilitated by cutting away the ventricle or auricle respectively; and thus bringing the under or posterior surface of the valve better into view. For more permanent demonstration, melted tallow or wax must be substituted for water.

WILLIAM BRINTON.

Brook-street, Grosvenor-square, Jan. 5, 1857.

### COMPOUND FRACTURE OF THE SKULL, WITH DEPRESSION AND LACERATION OF THE DURA MATER.—NO BAD SYMPTOMS.—RECOVERY.

[To the Editor of the Medical Times and Gazette.]

SIR,—There have been several cases of fractured skull published in the *Medical Times and Gazette* lately. I have sent you the particulars of a case that occurred in my practice some time ago, in case it should be of any use.

Nine months ago I was sent for to see a farmer's boy 14 years of age, who had been kicked by a horse. I found he had sustained a compound fracture of the skull over the parietal bone—the anterior portion; a piece of bone the size of a crown piece was depressed nearly half an inch. The dura mater was a good deal lacerated, and there was a large scalp wound about five inches in length. I saw him half an hour after the accident happened; he was just recovering from the shock, though still faint and cold, but quite sensible.

*Treatment.*—I gave him a small quantity of brandy as he was still faint. The depressed bone was so firmly fixed that I found it impossible to elevate it; I therefore concluded to wait for cerebral symptoms before trephining. I brought the edges of the wound together, retaining them in apposition by a couple of sutures and strapping: cold water dressing to be constantly applied; the hair to be cut short; to have a dose of calomel and low diet. This patient recovered without a single bad symptom, the scalp wound healing almost entirely by the first intention, and the boy was running about a fortnight after the accident happened; the only medicine he had being an occasional dose of aperient medicine. He is quite well at the present time. I am, &c.

GEORGE HOTHER, M.R.C.S.E. L.A.C.

Bargess Hill, Sussex, Jan. 2, 1857.

### PERFORATION OF THE MEMBRANA TYMPANI.

[To the Editor of the Medical Times and Gazette.]

SIR,—Under the foregoing heading, and also that of "The Artificial Membrana Tympani," and "The Artificial Tympanum," your readers have been entertained with some professional disputes that it is to be regretted came before the public at all, but particularly in the language employed in your columns. I, for one, and I am sure all other practitioners who wish to see aural medicine and surgery raised to the same position as ophthalmic medicine and surgery, hoped the dispute was at an end; when lo! a third party enters the field, and your last number but one contains a letter from Mr. W. Wright, who wishes to submit some observations on perforate membrana tympani to the Profession. The two cases he adduces are those of the late Duke of Wellington and a young officer from India. Every circumstance relating to the great Duke will, no doubt, be read with avidity, and if I ask for some further information you must attribute it to the natural inquisitiveness of an Irishman.

In 1822, we read that the Duke had his tympanal membrane ruptured by the report of a howitzer fired in his vicinity, and that an ignorant practitioner dropped into his ear a solution of nitrate of silver which passed into the cavity of the tympanum, where, says Mr. Wright, "it produced such mischief that the Duke's life was in great jeopardy, and his sense of hearing on his best side for ever obliterated." We hear nothing more of that side nor what appearances the parts presented at any time during the subsequent thirty years

of the Duke's life. On the right side there was, it appears, a small aperture. "When that hole was open the Duke heard tolerably well, because," says your informant, "the sound passed through, impinging on the round aperture and the base of the stapes, and so communicated the sound to the soft portion of the auditory nerve. As an illustration of this, on the 15th of June, 1838, the Duke sent his under-steward in a cab to fetch me to Apsley-house immediately." Well, now, some persons might cavil at the anatomy set forth in the first sentence, and ask what had become of the membrane of the fenestra rotunda, and say that if the sound impinged upon an aperture the Duke would not have heard at all; but I am sure the author meant the membrane of the inner drum-head. What I do feel a difficulty in is, to understand how sending an under-steward in a cab, on any particular day in the year, forms an illustration of the foregoing statement of the pathological state of a man's ear. The next sentence may, however, explain it: "A small scale of exfoliated epidermis had become placed over the hole in the membrane." "This," says Mr. Wright, "I removed with a small piece of cotton-wool upon one of my own prepared instruments, and the Duke heard instantly." So far so good, but I am still solicitous of knowing what this "prepared instrument" is with which the bit of cuticle was so adroitly taken out of the ear. It is scarcely fair to keep those things a secret from the Profession.

The second case is of comparatively little moment, except that it contains some curious physiological and therapeutic opinions. The man had otorrhœa with perforation, and heard, as is frequently the case, better at one time than another; upon which we read:—"The rationale of this is, the collection of mucus prevented the vibration of the internal membranes; the lotion which was injected (liquor plumbi and water) liquefied the mucus, and by the shaking of the body the obstructing matter descended through the Eustachian tube." Here I am again taken aback, for, according to my opinion, the preparations of lead render mucus opaque and thick, and the chemists will, I fear, not agree with Mr. Wright's opinion on this subject. Then as to the matter of the Eustachian tube, I can only say it reminds me of the story in the "Percy Anecdotes," of the application of the Doctor's directions, "When taken, to be well shaken." Does the discharge of an otorrhœa ever pass down the Eustachian tube? I believe not. The next paragraph refers particularly to myself, and says that I have related the case of a lady who accidentally employed "Mr. Yearsley's application of cotton-wool several years ago." This is a misstatement. To Mr. Yearsley belongs the credit of having first made known to the Profession the use of a piece of moistened cotton applied against the ruptured membrana tympani as a remedy in certain cases of deafness, but the lady whose case I have related in my "Practical Observations on Aural Surgery" devised the remedy, and made me acquainted with it three years before Mr. Yearsley promulgated his method of relief; therefore it cannot be said that she used Mr. Yearsley's method. While upon this subject I may state that, although I consider the piece of cotton a much more efficacious and generally useful remedy in the hands of patients than the gutta percha or caoutchouc with an attached stem, I know from experience that it is not necessary to have a portion of the membrana tympani uncovered, as has been lately stated in your columns.

In the bibliographical introduction to my Aural Surgery, I thought I had enumerated all Mr. Wright's works, "for all classes of deaf persons [even] the deaf and dumb, and those having diseases of the ear," from the year 1819 to about the period in which my book appeared. Here, however, I find I did not give credit where credit was due; I did not then know the following:—"When," says Mr. Wright, "I was writing my little work in 1839, my valued friend, Sir Astley Cooper, wrote a part of the article on the Perforation of the Membrana Tympani, for which he received the Copleian Medal, in 1800, and he gave me permission to use it in his name." Now every thing Sir Astley Cooper wrote ought to be preserved, and ought to be acknowledged. Not having access to the work alluded to, I cannot say whether due acknowledgment has been made for what Sir Astley Cooper wrote, but if not, Mr. Wright should, I think, in justice to the memory of Sir Astley Cooper, state how much of that essay upon the Membrana Tympani he really did write, at what page it begins, and where it ends.

I am, &amp;c.

W. R. WILDS.

Merriion-square, Dublin, Jan. 2, 1858.

## CAUSES OF DENTAL CARIES.

[To the Editor of the *Medical Times and Gazette.*]

SIR,—I observe in the *Medical Times and Gazette* of December 26, a long communication by Mr. Donaldson Mackenzie, in which he expresses his conviction that the cause of dental caries consists in some peculiar condition of what he terms the "salivary admixture." Now as acidity must, apparently, be the condition here alluded to, as Mr. Mackenzie refers to the alternate acid and alkaline state of this fluid, we know that these states naturally exist at certain times in all cases, and without the existence of any disease, and without incurring any damage to the teeth at all.

In March, 1852, I published an article in the *Edinburgh Monthly Journal of Medical Science*, in which I advanced the opinion that the saliva exercised a protective and preservative influence over the teeth: to that opinion I still adhere, and the interest attaching to the question must be my excuse for now asking Mr. Mackenzie upon what grounds he arrives at the conclusion that this fluid acts in a destructive capacity.

Not to enter into details, I would merely offer the following reasons for the opinions I entertain:—

1st.—Were the salivary admixture of such destructive tendency, its being normally and constantly present in direct contact with the teeth, would be a fact unparalleled by any other instance in the whole animal economy.

2nd.—Were this fluid the cause of dental caries, the teeth would in their decay bear at least some ratio to their exposure to such pernicious agency. This, however, is not the case.

3rd.—Were the salivary admixture of so deleterious an influence, certainly those teeth most exposed to, and most constantly immersed in it, would not be those which are found to be positively the least subject to decay, as is the fact; e.g. the lower incisors. I am, &c. JOHN SMITH, M.D.

Lec. on Dental Surgery, Med. School, Surgeons' Hall, Edinburgh, 12, Dundas-st., Dec. 29, 1857.

## SURGEONS TO RAILWAY COMPANIES.

[To the Editor of the *Medical Times and Gazette.*]

SIR,—Your remarks on Mr. Adams's evidence, and his own letter, strongly attracted my attention, because I have had personal knowledge of such practices as referred to in the evidence having been pursued for some years, and trusted that some day or other they would receive notice.

But, perhaps, a few cases would be better than any amount of denunciations.

First, then, an accident occurs on a certain line, whereby two women, besides many others, were hurt. The address of one was known by the Company's officials, but, fortunately, the other was not. They sent for their Medical attendant, but after he had seen the first, the Company's Surgeon called: "Sorry, my good woman; you will be a week bad; here are thirty shillings for you to pay for a nurse, etc., during that time, and a prescription which I shall write to cure you. We shall pay your doctor for the trouble he has had, etc., and you sign this paper."

The doctor, on finding what had occurred, applied for his fee, but his claim was repudiated by the Company. However, he profited by experience, desired the other patient, who was not more severely injured, to keep quiet, and not let the Company know until fairly out of danger; when the Company's Surgeon was made acquainted with her case. Upon receiving information he tries to see her unknown to her regular attendant, alleging that he was a Physician from the Company, and had a right to see her, at the same time stating to her husband (for he was not privileged to see the patient this time) that he was empowered by the Company to offer compensation, and not to be alarmed at him, as *he was no lawyer*. At length, to obtain an interview, he had to call upon the gentleman in attendance, and gave as compensation £150 clear, and £100 expenses. Rather different this to the thirty shillings!

No person, excepting a Medical man, could have a chance of settling affairs in this manner; for who is more trusted in the hour of suffering than the doctor, little dreaming that he is sometimes coming to catch them asleep!

Surely we have fallen on unlucky days, when men in the front ranks of our Profession do such things.

December 22, 1857.

I am, &amp;c.

M. D.

## REPORTS OF SOCIETIES.

## THE PATHOLOGICAL SOCIETY.

TUESDAY, JANUARY 5.

Dr. WATSON, President, in the chair.

Dr. BRINTON, on behalf of Dr. Wilks and himself, reported further on Mr. Balding's specimen of

## EPITHELIAL CANCER (?) OF THE OESOPHAGUS.

On further examination they felt inclined to consider some portions of the ulcer as carcinomatous. The greater part was manifestly not so, and they did not consider that respecting the most suspicious the evidence was positive.

Mr. HENRY recapitulated the facts of this interesting case, commenting strongly upon the very different opinions which had been pronounced on the nature of the disease. Dr. Goodfellow, Mr. De Morgan, Mr. Sibley, Mr. Flower, and its exhibitor, Mr. Balding, had all examined it, without feeling a doubt as to its really being epithelial cancer. This opinion Drs. Brinton and Wilks in their first report had held to be erroneous, regarding it as a simple ulcer. Meanwhile, however, Mr. Quekett had given an unqualified opinion as to its being cancer. In their second report Drs. Brinton and Wilks seemed still to be in doubt.

Dr. BRINTON explained that there was only one very small part of the ulcerated surface in which any histological features indicative of epithelial cancer were discoverable, and this part had on the first occasion escaped examination. The case was still one of much difficulty and doubt.

Dr. WILKS stated also, that although they had consented to qualify their second report, he still felt much doubt as to whether the disease were really cancer. He was tolerably familiar with such specimens, and this differed very greatly from all others that he had seen.

Dr. POLLOCK showed a specimen of

## EPITHELIAL CANCER OF THE LARYNX.

A man, aged 57, had died after a six months' illness Aponia, dysphagia, pain in the neck, and spasmodic orthopnea, had been the chief symptoms. There had, indeed, been occasional aphonia for several years. The respiratory murmur was feeble on each side. There was no signs of pulmonary disease. He died after a long-continued paroxysm of dyspnea, evidently from mechanical obstruction. He was not cachectic. The autopsy showed cancerous (epithelial) ulceration of the larynx. The rima glottidis was almost closed by the growth. Dr. Pollock raised the question as to whether tracheotomy ought not to have been performed.

Mr. CURLING showed a specimen of

## EPITHELIAL CANCER OF THE LARYNX.

He stated that this case would, he thought, furnish a good answer to the important question of practice raised by Dr. Pollock. The patient, a gentleman aged 63, under the care of Mr. Debenham, of the Commercial-road, had long suffered from symptoms of chronic laryngitis. At length the difficulty of breathing became such that it was thought he could not live many days. Tracheotomy was now performed. He recovered well, and wearing ever after a tracheal canula, was able to walk considerable distances. The indications of laryngeal ulceration, however, still persisted, and he finally died of exhaustion consequent on these. He had lived nearly a year after the operation. The autopsy showed epithelial cancer of the larynx, which was extensively ulcerated.

Dr. ANDREW CLARK had carefully examined the specimen with the microscope, and confirmed the opinion as to its malignant nature.

Dr. ANDREW CLARK entered at some length into a description of the microscopic features of the specimen, which were illustrated by drawings and mounted preparations. Alluding to Mr. Balding's specimen, about which so much difference of opinion had been entertained, he stated that he thought the discrepancy was to be accounted for by the very fallacious character of the evidence relied on, as distinguishing epithelial cancer. He would assert most strongly that the laminated capsules were by no means peculiar to it, but were found under various other conditions. He still believed the

opinion of Drs. Wilks and Brinton to be correct, and that it was not really cancer.

Mr. NUNN brought before the Society specimens illustrating the

#### DISTANCE BETWEEN THE OVARY AND UTERUS.

The specimens showed the right ovary about half-an-inch nearer to the fundus of the uterus than the left. He believed that this condition was due to the general law, of a less perfect development on the left than right side of the body. He thus thought that the fact was an anatomical rather than a pathological one. He had observed its occurrence in many specimens.

Mr. FLOWER showed a specimen of

#### EPITHELIAL TUMOUR OF THE SCIATIC NERVE.

The patient had died in the Middlesex Hospital of epithelial cancer of the uterus and vagina. At the autopsy extensive malignant disease of those parts and of the lumbar glands was found. She had before death suffered from extreme pain down the right leg. Within the sheath of the right sciatic nerve, before its escape from the pelvis, was found a mass of epithelial cancer, the size of an egg elongated. Mr. Flower thought that this growth was not one *de novo*, but had been produced from the larger pelvic mass by prolongation along the course of the small artery, passing into the nerve-sheath.

Dr. VAN DER BYL related the particulars of a case of death from

#### PLUGGING OF THE MITRAL VALVE.

The patient, a woman, had for some time suffered from chest symptoms,—cough, palpitation, and a mitral bruit. She died very suddenly, in what had at first seemed a fainting fit. At the examination a large soft fibrinous mass was found, occupying the mitral opening, and partially plugging it. Several similar but smaller masses hung pedunculated in the auricle, none of them possessing organic connexion with its walls. He thought it was evident that the accidental impaction of this mass had been the cause of death. The mitral opening was much narrowed by old disease.

Dr. BRISTOWE and Mr. WOOD, on Mr. Shilleto's specimens of

#### MASSSES PASSED FROM THE INTESTINES.

reported that they consisted only of undigested portions of potatoe. The starch appeared to have been to a great extent removed, and in many cases the debris of other alimentary matters adhered to them.

Dr. HANLEY next showed specimens of

#### TUBERCULOUS DISEASE OF THE SUPRA-RENAL CAPSULES.

A man, aged 35, had died under Dr. Walshe's care in the University College Hospital. The supra-renal capsules were both of them very much enlarged and thickened, being as large as flattened bantam's eggs. No trace of the medullary substance, could be found by the microscope. The cortical substance, although infiltrated with tubercles, still preserved some normal cells. The tubercular deposit appeared to have been first deposited in the medullary portion. The man had died of pulmonary phthisis, and no bronzing of the skin had been noticed.

Dr. BRINTON described a case of

#### POLYPOID GROWTH FROM THE ILEUM.

The polypus was a pedunculated fatty growth, the size of a filbert. Dr. Brinton remarked, that to apply the term polypus to any forms of intra-intestinal growth seemed almost superfluous, as they never grew to any large size, or caused serious symptoms.

Dr. ANDREW CLARK showed specimens from a case of

#### LEUCOCYTHEMIA.

"Unless fibrin were held to be heteromorphous, of which there was no proof, the case illustrated the total absence of fibrin from the blood." The patient, a woman, had died under Dr. Ramsbotham's care in the London Hospital, having shown for some months the waxy pallor and other symptoms of the disease. At the autopsy the spleen was found much enlarged. The blood did not coagulate.

#### ANNUAL REPORT, &c.

This meeting was the anniversary one of the Society. The Report of the Council was read, as also the Treasurer's

financial statement. Neither of these call for any special moment. The Society is in every respect in a prosperous condition, but if the excellence of its volumes as regards illustrations, etc. is to be kept up, an addition to its income (by new members) is very desirable. The list of officers as given in our last number having been submitted to the ballot, the gentlemen named in it were declared duly elected.

### WESTERN MEDICAL AND SURGICAL SOCIETY OF LONDON.

Dec. 4th, 1857.

W. MARTYN, Esq., Vice-President, in the chair.

Mr. ELLIS read some notes on the

#### DEFECTS OF ORDINARY ESCHAROTICS, WITH SUGGESTIONS FOR THEIR IMPROVEMENT.

After giving a definition and general history of escharotics, the author made some observations upon the mode in which they affected the tissues, either by destroying their continuity, organization, and life, by combining with them, or by a mutual decomposition forming new compounds. He then remarked upon the various chemical effects of acids, alkalies, and metallic salts; the first acting as oxidizing agents, the alkalies forming compounds with albumen and fibrine, and the metallic salts uniting with albumen to form metallic albuminates. Enumerating the acids in general use as escharotics, nitric, hydrochloric, and sulphuric, he gave the preference to nitric acid, but stated that he had found a difficulty in procuring it of sufficient strength, and of a sp. gr. of 1.50; he thought its utility much impaired by its fuming property and intense rapidity of action; also from the sore made by it being very superficial and its effects not being permanent. Hydrochloric acid he considered should have a sp. gr. of 1.21, but it was feebler than nitric acid. Sulphuric acid he stated was weaker than nitric, but stronger than hydrochloric acid; it had its advantages in not fuming; for obvious reasons it should be applied by means of asbestos. The author then gave his experience of the alkaline escharotics, hydrate of potassa, and potassa c. calce, the former of which, he said, although strong and quick in action, was defective from its deliquescence, its liability to spread, and its friability; the latter although comparatively free from the above objection was sometimes followed by hæmorrhage. As Mr. Ellis was chiefly alluding to the use of the above escharotics to the os and cervix uteri he had found in the friability of potassa c. calce a great defect, also that great contraction of the canal of the cervix followed its application. Of the metallic salts he observed that nitrate of silver was extremely valuable as a mild escharotic, and that its effects were quite superficial. As usually sold he had found it much adulterated, which greatly depreciated its value; he recommended the crystallized salt to be used instead, and melted into sticks when required.

Another defect he had found in its brittleness, which rendered it dangerous when applied to a part like the inner surface of the cervix uteri. To obviate this evil he has been in the habit of melting the caustic in a small bullet-mould having a core; this gives him a small globe, with a hole running through it, which, by means of a pin, is easily fixed to the holder.

Chloride of zinc he showed to be an extremely powerful and valuable agent; that it acted quickly and deeply. He uses it mixed with flour, and made into a paste with water.

Deliquescence and giving great pain were its principal defects.

Having made a few observations upon the actual cautery, he concluded by exhibiting the implements he used in applying the various escharotics he had just mentioned, and the mechanical contrivances for melting the nitrate of silver, and attaching it to the holder.

ELECTIONS OF THE ACADEMIE DE MÉDECINE.—For the ensuing year, M. Lavier has been elected president; M. Cruveilhier, vice-president; and M. Devergie, annual-secretary; M. H. Dubois (of Amiens) retaining his post of perpetual-secretary.

## MEDICAL NEWS.

## DEATHS.

**BAUDENS.**—Military Medicine in France has sustained a great loss in M. Baudens, one of the chief Medical Inspectors of the French army, who died on the 27th ult. The autopsy has revealed cancer of the liver; and no doubt his arduous tour of inspection in the Crimea, exposed as he was to various miasmatic influences, hastened his death. We lately furnished our readers with a copious abstract of the very interesting narration he gave of his mission to the East, and we will shortly lay before them a brief account of his life and services.

**DIXON.**—Dec. 30th, at Norton, near Stockton-on-Tees, Henry Dixon, aged 30.

**FELLOWES.**—Dec. 30th, at Langstone Cottage, near Havant, Sir James Fellowes, M.D., F.R.S., Inspector-General of Military Hospitals, aged 86.

**JALLAND.**—On the 8th of November last, at Secunderabad, Madras, William Gibson Jalland, Assistant-Surgeon, 24th Regiment N. I.

**LUARD.**—Dec. 25th, at Florence, Peter Francis Luard, M.D.

**MILNER.**—On the 4th inst., at his residence in Manchester, Farquhar Milne, aged 38, M.R.C.S., Eng.; and L.S.M., 1842.

**PRETTY.**—Dec. 30, at Bayham-terr., Dr. J. R. Pretty. This gentleman was the son of Mr. W. Pretty, a well-known and highly-respected general practitioner, near Regent's Park. Dr. Pretty was a member of the College of 1845, a Licentiate of the Hall of 1846, and he took the St. Andrews degree in 1854. His "Aids during Labour" is a well-known book, and he has contributed several papers to this Journal: one of which, On Flooding after Labour, was hardly published before his death.

**ROYLE.**—At his residence, at Acton, on the 2nd inst, Dr. Forbes Royle. He had been unwell for several weeks previously, but up to the last moment his illness was not believed to be of a dangerous character. Dr. Royle's profound knowledge of the material resources of India, especially in the vegetable kingdom, and the warm interest which he took in everything calculated to increase the industrial prosperity of our Eastern empire, render his death a public loss. He was a Fellow of the Royal Society, and in his own department of science had a European reputation. He was an M. D. of Munich, formerly Professor of *Materia Medica* at King's College, and the author of the well-known manual of "*Materia Medica*" in Mr. Churchill's series. He was an exceedingly kind-hearted, agreeable man, and his death will be much felt by many attached friends.

**SMYTH.**—Dec. 29th, at his house in Sackville-street, George Beatty Smyth, M.D., Edin., 1837; L.R.C.P.E., 1845. Aged 44.

**WOOD.**—On the 25th of December, at 34, Broad-street, John Freeman Wood, aged 60, M.R.C.S. Eng. 1820; L.S.A. 1822.

The following are the Medical casualties reported in General Havelock's force since leaving Cawnpore, 29th Sept. 1857.  
**Artillery.**—Assistant-Surgeon Bartrum, killed. H.M. 90th Foot.—Assist.-Surg. Bradshaw, slightly wounded. 78th Highlanders.—Dr. McMaster, slightly wounded, Oct. 15.

## APPOINTMENTS.

At a meeting of the Governors of the Sheffield General Infirmary, held on December 30th, 1857, Mr. Gratian C. Barry Hart was unanimously elected to the office of House-Surgeon to that Institution, in place of Mr. Hall, resigned.

**DEATH OF AN ENGLISH SURGEON IN CHINA.**—The *Times* correspondent at Hong Kong says, "The same letters tell me of the death of Mr. Beale, one of the Medici of Shanghai. He had accumulated an enormous fortune without contracting the limits of a most lavish expenditure. He had just resolved to return home. I was his guest for some time at Shanghai, and was indebted to him for much information. He had dis-

cussed with me his plans for his new career in England, and his influence would have been great upon all questions relating to China. But while he was gathering in the threads of his multifarious operations Death put his hand upon him. He died deliriously, pointing out the headlands and the cities he fancied he saw in his voyage towards England. So perhaps he was happy in his death. It is frightful to look back upon the number of youthful and energetic men whom I have known intimately during my few months' sojourn in the East, and who have succumbed to this climate. Our staff officers and our doctors and our commissariat are ludicrously disproportionate to our present force."

**VITAL STATISTICS OF THE ALUMNI OF HARVARD COLLEGE, MASSACHUSETTS.**—The *Boston Medical Journal* gives some account of an elaborate paper by Professor Peirce upon this subject. The basis of the computation is the triennial catalogue of 1857, which embraces the names of 6876 alumni, of whom 2394 survive, while the dates of the deaths of a large proportion of the 4482 who are deceased have been accurately ascertained. The duration of life is ascertained by assuming the age at graduation to be 21, which is, probably, very nearly exact. One of the most striking results of the inquiry is, the unusual longevity of the alumni, compared with the duration of life by the Prussian tables. Thus, the probable average duration of the life of an alumnus 10 years after graduation is 35 years, while that of an individual of the same age, according to the Prussian statistics, is only 31.3 years. The difference at a later period is still more remarkable. At 20 years after graduation, or at the age of 41, the alumnus has 27.8 years to live, while the Prussian tables would give him only 23.4. At the age of 56 his chance is 17.2 years, instead of 12.4 years by the Prussian tables. Another interesting feature is, that those scholars who graduated with distinction are longer lived than those who have not been remarkable for scholarship.

**BOYLSTON MEDICAL PRIZE QUESTIONS.**—The questions for 1858 are,—1. Spermatorrhœa, its causes, consequences, and treatment. 2. Human parasites, animal and vegetable, their anatomy, development, natural history and treatment. A premium of 60 dollars, or a gold medal of that value will be awarded to the best essayists. Dissertations to be forwarded by the first Wednesday in April, 1858, to Dr. Edward Reynolds, Harvard University. The subjects for the year 1859 are,—1. New and useful views upon any subject of medicine and surgery.—2. Tubercle, its pathology, and especially its relation to inflammation.

**PROSECUTOR TO THE FACULTY OF MEDICINE OF PARIS.**—M. Marc Sée, as the result of a brilliant *concours*, just concluded, has been appointed to this important post in the Paris Faculty.

**THE "ATHENÆUM" ON THE MIDDLESEX REPORT ON CANCER.**—"This Report is an attempt to explain how the medical officers of Middlesex Hospital came so far to compromise themselves with their medical brethren as to allow the possessor of a secret remedy of vaunted efficacy in cancer to practise upon the patients of that hospital. Unfortunately for this institution, they have a fund which is exclusively devoted to the cure of cancerous patients. Dr. Fell applied for permission to employ his remedies on these poor patients, and in an evil hour he was allowed to treat secretly the patients of the hospital,—with what results Dr. Fell's own book records. The surgeons of the hospital, having taken the false step of allowing the holder of the secret to practise within their walls, have felt it necessary to give to the world this Report. Those interested in the treatment of cancer will undoubtedly read it with great interest, but we regret that any body of professional men should have placed themselves in a position of pleading the great temptation they were under for breaking through one of the noblest rules of conduct that any profession can boast."

**THE CHOLERA** is very prevalent and fatal at Bagdad.

**THE MORTALITY IN VIENNA IN 1856.**—During the year 1856 there died 5735 male, and 5385 female adults; 4545 male and 4097 female children from birth to ten years old inclusive; and 447 male and 368 female infants were born dead; making a total of 20,577 deaths; 10,727 occurred in males and 9850 in females. Of these, 1568 are returned as dying of marasmus and hectic fever, 638 of debility from old age (70 and upwards), 1820 of "debility," 48 of gangrene, 202 of apoplexy or suffocation, 1370 of convulsions, 1777 of ner-

vous fever and typhus, 80 of variola, 13 of measles, 81 of scarlatina, 840 of diarrhoea and dysentery, two of cholera, 89 of convulsive coughs, 1443 of affections of the brain, including hydrocephalus, 226 of croup and other affections of the throat, 267 of disease of the heart and large vessels, 1180 of affections of the abdominal and pelvic organs, 37 from metastatic deposits, 5829 of the various forms of tuberculosis, 613 of inflammation of the lungs, 61 of scrofula, 490 of dropsies, 555 of blood diseases, 65 of bodily injuries, 426 from various diseases, and 23 from suicide.

**HOW TO GET INTO PRACTICE.**—"A Physician" writes as follows to the *Morning Post*:—"A young Physician having completed his education takes up his residence in a district, mounts a brass plate, and looks out for patients; but Physicians are very numerous, perhaps the Profession is overstocked, patients are few, and something must be done to acquire a name and establish a reputation. Perhaps he has some half-dozen or dozen well-to-do friends, kind of heart, and at the same time deeply interested in his welfare. He presents to their sympathising feelings a picture of the untended sickness of their district, and suggests what an excellent thing it would be to get up a dispensary. It is not likely that one man will be strong enough to achieve this feat single-handed; but he is joined perhaps by another Physician in similar circumstances and with similar aspirations—say also by two surgeons and two accoucheurs—and with their combined efforts the dispensary is established. A president, committee, treasurer, honorary secretary, and collector are easily provided; then follow well-dressed annual reports, charity sermons, charity dinners, &c. The professional aspirant has now not only a field for practice, but he is in a position to have his fame reported to those who need his skill, and can afford to pay for it. To attend a gentleman's servant is desirable, because fame finds its way from the kitchen to the drawing-room; the artisan or petty shopkeeper who don't pay can at any rate spread the good doctor's reputation to those who will. It is also a known fact that dispensary Medical men have not seldom been in the habit of inviting the best dressed and respectable-looking of their dispensary patients to wait upon them in the morning at their private residences. This attention is flattering to them; they have the feeling that they are treated as if they had a fee to give, and they make a good appearance in a young Physician's waiting-room by creating the impression of extensive practice in the minds of accidental callers, or of the stragglers who come with fees in their pockets. When the young Physician has found his way to a paying practice he probably withdraws from active duty under the designation of consulting physician, and leaves the governors to elect another aspirant."

**THE PREACHING MANIA OF SWEDEN.**—This curious epidemic is described in an interesting letter by an "F.R.S." in the *Morning Post*:—"About the middle of summer, in the year 1841, an unusual mental or nervous malady began to first show itself among the youth of several districts verging towards Lake Wener, but gradually spread over other localities in the central portion of Sweden. By Swedish medical authors it was called 'Predikosjukan,' or 'epidemiaka religioea ecstas,' which signifies 'preaching mania,' or 'epidemic religious ecstasy.' Since the period when the dancing mania prevailed in Germany, about 1374, Tarantism in Italy, during 1565, or the dance of St. Medard—the convulsionnaires of Paris—towards the middle of the last century, and continued till the Revolution, nothing analogous to the epidemic which so recently raged in Sweden has been observed in modern Europe, with perhaps the exception of the fantastic movements exhibited by the Jumpers in Wales, chiefly about the middle of the last century. Such being the case, a brief outline of the affection just named may not seem uninteresting to general readers, especially as the existence of such abnormal psychological phenomena as those about to be described are very little known in England, even by professional persons. The preaching epidemic of Sweden prevailed to its greatest extent in the province of Ellsberg, being very common in the parish of Björsäter, as also in the commune of Scaraborg, on the south side of the Wener Lake, already mentioned. It chiefly affected young persons and mostly females from twelve to fifteen years old, although sometimes even children, and occasionally women beyond their twentieth year. Several thousand persons are said to have been attacked, and some authorities report upwards of

5000 during the period of about sixteen months, or while the malady continued. The first symptom noticed was generally the young person seized falling down as if in a trance—this being followed by tremblings and shakings, but particularly by quakings of the arms and legs, and a sensation as if something were crawling on the limbs. The parties attacked always fell backwards when the trembling fit began, and they then knocked their heads against the floor, often with much violence. Subsequently they were affected with strong and vehement movements, and catching at the hands of bystanders. Afterwards the sufferer, if a girl, seemed engaged in dressing herself like going out to a party. Occasionally they become so violently convulsed that their bodies were bent backwards in a circular form, whereby the head and feet nearly came into contact. In other examples, the sufferers appeared like being engaged in a pugilistic combat with themselves, and in tearing their hair, or as if hitting another combatant. These symptoms usually marked the malady's first stage, when the patient now became quiet and calm, having the hands almost constantly folded over the chest. Very soon they began to speak or preach; sometimes in a recumbent position with their eyes shut, and apparently senseless or entirely unconscious; but in other instances the eyes were open, while the party stood bolt upright. The address now made, or sermon, often so designated, was short and generally on religious questions. Sometimes where several persons became simultaneously affected as above described they were often joined by idle passengers, and then groups of people rambled through the village or town singing hymns, whereby they caused great uproar and confusion, which required the police to interfere. In the spring of 1842 this epidemic spread so widely, and created such an impression where it prevailed that Government was obliged to make inquiry, and so forth. It, however, ceased almost entirely about autumn; and since that period only solitary cases have occurred. Medical authors in Sweden considered the extraordinary complaint now succinctly noticed as originally a bodily disease peculiarly affecting the mind, and that it was very frequently influenced by imitation, while young females were almost constantly its special victims."

## VITAL STATISTICS OF LONDON.

Week ending Saturday, January 2, 1858.

### BIRTHS.

Births of Boys, 1041; Girls, 892; Total, 1933.  
Average of 10 corresponding weeks, 1847-56, 1437.

### METEOROLOGY.

From Observations at the Greenwich Observatory.

Mean height of barometer	...	...	...	30.357 in
Mean temperature	...	...	...	39.1
Highest point of thermometer	...	...	...	48.0
Lowest point of thermometer	...	...	...	30.8
Mean dew-point temperature	...	...	...	37.4
General direction of wind	...	...	...	W.S.W.
Whole amount of rain in the week	...	...	...	0.00
Amount of horizontal movement of air in the week	...	...	...	140 miles

### DEATHS.

	Males.	Females.	Total.
Deaths during the week	755	676	1431
Average of the ten years 1847-56	...	...	1288
Average corrected to increased population	...	...	1417
Corrected average for corresponding week in ten years 1847-56	658.8	620.2	1288.0
Deaths of people above 90	0	0	0
Deaths in 13 General Hospitals	58	24	82

### DEATHS IN SUB-DISTRICTS FROM EPIDEMICS.

	Population. 1851.	Measles.	Scarlatina.	Hooping-Cough.	Diarrhoea.	Cholera.	Typhus.

South	616,035	12	4	8	3	1	12
Total	2,362,236	45	25	57	12	1	22

## TO CORRESPONDENTS.

Dr. Conolly's second paper, and a Portrait illustrating "Suicidal Melancholy," will appear next week.

Dr. Hamilton.—Mr. Gray, of Goswell-street, supplies very good artificial eyes.

M.D.—We have not seen the recommendation alluded to.

Mr. Birkett's letter shall be inserted next week.

A Physiologist may think the publication of formulae not very dignified, but we can assure him that a very large proportion of our correspondents are anxious to know the precise manner in which Hospital Physicians and Surgeons prescribe various remedies. There are many things which appear common and simple to the "Physiologist," but which are valued by the man who has to encounter the difficulties of actual practice.

G.—Application to the Secretary of the Government Emigration Office, Westminster.

Curious.—The valerianate of zinc is coming into much more general use.

Mr. A.—We do not insert notices of births or marriages in the *Medical Times and Gazette*.

Noli me tangere.—The queries could be answered by any medical man—except that as to the Triemar, which is a quack preparation.

Mr. Wright.—A Guy's Man.—The report was incorrect. The pea was removed by the dresser in the usual manner, by injecting warm water.

## THE ARTIFICIAL TYMPANUM.

Mr. Yearsley has sent us some further correspondence on what he calls the Artificial Tympanum. Other demands upon our space, however, only permit of our stating that Mr. Harvey prefers the wetted cotton to the india rubber or gutta percha. With regard to the opinions of Dr. Sapolini, of Turin, referred to by Mr. Toynbee, Mr. Harvey says, in a letter to Mr. Yearsley, "Dr. Sapolini attended my practice for eight months, during which time we had frequent conversations on this subject, as well as on other theories advanced by Mr. Toynbee, and I most distinctly understood him to say that he concurred with me in the views I have enunciated in this reply to you," i. e. the utility of the cotton wool, and its superiority over the artificial membrane.

Mr. Garland shall receive a note from the publishing office.

We made inquiries as to the card forwarded to us by our correspondent last week, and the Physician accused states as follows:—

"As to the enclosed card of my removal being distributed from house to house, I need hardly say that it is not true, for I think no one who has known anything of my views on such matters and of my scrupulous conduct since I have been in the Medical Profession would believe it to be true, and I thank you for giving me the opportunity of denying so ridiculous a charge. When I removed a short time since, I made out a list from my diary of all my patients, writing their names out of my diary on envelopes. I had just so many cards printed as there were envelopes thus directed, and posted them the day after my removal, thus securing as far as possible that this card should not fall into the hands of any one who was not already a patient of mine. Several were returned to me by the Dead-letter office, in consequence of the patients having changed their residences since their last visits to me, and I presume that this circumstance may have given rise to the mistake. I am, &c. L.R.C.P."

Medicus.—You have full power to order away street musicians who may disturb you in hours of professional occupation. The following is the clause of the 2nd and 3rd Vict. cap. 47, sec. 57:—"And be it enacted that it shall be lawful for any householder within the Metropolitan police district, personally, or by his servant, or by any police constable, to require any street musician to depart from the neighbourhood of the house of such householder on account of the illness of any inmate of such house, or for other reasonable cause; and every person who shall sound or play upon any musical instrument in any thoroughfare near any house after being so required to depart, shall be liable to a penalty of not more than forty shillings."

An Army Surgeon.—We have not noticed the controversy between Sir John Hall and Dr. Sutherland as yet, because a reply is to be published to the last paper of Dr. Sutherland, and we wait until the whole case is submitted to the Profession before commenting on it.

## FEES.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.  
Sir,—After the death of Mr. J. Dalrymple, it has come to light that four aspiring oculists met, and adopted a resolution that none of them would perform any important operation upon the eye for less than one hundred guineas. I am anxious to know whether this proceeding should be viewed by the Profession and the Public as another example of the speciality mania now so disgraceful to the present age, and whether the names of these individuals should be concealed.  
Jan. 5, 1858. I am, &c. SPECTATOR.

Errata.—In our notice of the case of Mr. Symes, of Bridgewater, last week, "extraordinary verdict" was printed for "exculpatory verdict."—In the pass list of Apothecaries' Hall, published in our last number, Mr. Woolmer's name should have been printed "Shirley Edmonds Woolmer."

## BEGGING-LETTER ASSURANCE OFFICES.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.  
Sir,—I think it well to send you the enclosed, as it will be a caution to others if you will insert it *pro bono publico*. I am, &c. MEDICUS.

"Union Life Office, Norwich, Dec. 5, 1857.  
"Sir,—In reply to your letter of the 4th inst., I beg to state that the Directors of this Society pay for no Medical reports except those furnished by their own appointed examiner. We must, therefore, beg to refer you to the parties for whom you filled up the certificates for payment of your fees.  
I am, Sir, your obedient Servant,  
D. T. CORRIE."

## GREAT NORTHERN HOSPITAL, KING'S CROSS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—In a late number of the *Medical Times and Gazette*, I find a notice abstracted from the *Morning Post*, which is not at all favourable to this Institution, and calculated to do harm. May I ask you kindly to insert the enclosed abstract from the *Morning Herald*, of December 24th, 1857, which truthfully shows the necessity of the present Hospital.  
January 6th, 1858. I am, &c.

J. RIMBER, Hon. Assistant Secretary.

"THE GREAT NORTHERN HOSPITAL.—This institution has been established to meet the Medical necessities of the poor populations of Islington, Agar, Camden, Somers, and Kentish Towns, New Smithfield, and Highgate. It is situated in the York-road, King's-Cross, adjoining the Great Northern Railway Company. To Mr. Statham, one of the Surgeons to the institution, is due the credit of having at his own private cost founded the nucleus of the present hospital. During the six months this gentleman worked this little institution no fewer than 23,000 out-patients received gratuitous relief, while 46 in-patients were received into the hospital, and had every care bestowed upon them. The work becoming too laborious for the exertions of a single Medical officer, the institution was handed over to some gentlemen who kindly undertook the duties of a committee; the premises were enlarged, and rendered more suitable for hospital purposes. Concurrently with these alterations a full Medical and Surgical staff was elected, consisting of three physicians and three surgeons; three junior physicians and three junior surgeons; a physician accoucheur, with ophthalmic, aural, and dental surgeons. One feature worthy of notice is, that the hospital is free to all sick and destitute persons, no form of recommendation being required. The average of daily patients is over 300. The report lately issued by the committee states that from January the 1st to October the 1st, 1857, 51,448 poor people received gratuitous assistance; of this number, 22,866 were new out-patients, and the remaining 28,582 included those who had visited the hospital more than once. The Medical cases amounted to 15,907, the surgical to 6059; 78 cases received in-door relief. It is to be hoped that so excellent a commencement of a good work will not fail in its future endeavours, for want of means, to afford that comfort and assistance which it has hitherto done."

COMMUNICATIONS have been received from—

Sir RICHARD MAYNE; Mr. WILDE, Dublin; Dr. SNOW; Dr. PRIESTLEY; Dr. WALLER LEWIS; Dr. ACLAND; Mr. PRESCOTT HEWETT; Mr. BIRKETT; Dr. HARE; Dr. WILKS; Dr. ALTHAUS; Dr. BRINTON; Mr. RUMSEY; Mr. WHITE COOPER; Mr. GAY; Mr. GARLAND; Mr. YEARSLEY; Mr. ASHDOWN; Mr. DALE; Mr. MACKENZIE; Mr. GRAY; Dr. HAMILTON; Mr. RIMBER; Mr. S. PARKER; Mr. MILLARD; Mr. COULCHER; Mr. G. HART; Mr. ROSENTHAL; Mr. ANDERSON; Dr. H. DOBELL; Mr. MURTS; Dr. CHAMPIONNIERE; Dr. MCARTHY; Dr. SPIERS; Mr. MOORE; Mr. FULLER; A COBONER; Mr. T. GRAHAM; Mr. W. HALL; Mr. C. BECKETT; Mr. R. T. METCALFE; Mr. O. RICHARDS; Mr. H. E. SHAW; Dr. R. CROTHERS; Mr. ROLLS; Mr. J. WILLIAMS; Dr. W. FOLEY; Mr. J. BLOMFIELD; Dr. F. W. BLAKE; Mr. R. STEVENS; Mr. W. CLARK; Mr. H. R. FOQUETT.

## APPOINTMENTS FOR THE WEEK.

Jan. 9. *Saturday (this day).*

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m. Westminster, 1 p.m.; King's, 2 p.m. Charing Cross, 1 p.m. MEDICAL SOCIETY OF LONDON, 8 p.m. GUY'S PHYSICAL SOCIETY, 7 p.m.: Mr. Stokoe, "On Disease of the Heart."

11. *Monday.*

Operations at the Royal Free Hospital, 1 p.m.; Metropolitan Free Hospital, 2 p.m.; Orthopaedic Hospital, 3 p.m. JURIDICAL SOCIETY, 8 p.m.

12. *Tuesday.*

Operations at Guy's, 1 p.m. ROYAL MEDICAL AND CHIRURGICAL SOCIETY, 8½ p.m.; Mr. Tulko, "On the Pathology and Morbid Anatomy of Glaucoma." Dr. Marcet, "On the Analysis and Immediate Principles of Human Excrements." ZOOLOGICAL SOCIETY, 9 p.m.

13. *Wednesday.*

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m. Orthopaedic Hospital, 3 p.m. MICROSCOPICAL SOCIETY, 8 p.m. NORTH LONDON MEDICAL SOCIETY, 8 p.m.: Paper by Mr. Cousins.

14. *Thursday.*

Operations at St. George's, 1 p.m.; Middlesex, 12½ p.m.; Central London Ophthalmic, 1 p.m.; London, 1½ p.m. ROYAL SOCIETY, 8½ p.m.

15. *Friday.*

Operations at the Moorfields Ophthalmic, 10 a.m.; Westminster Ophthalmic, 1½ p.m. WESTERN MEDICAL AND SURGICAL SOCIETY, 8 p.m.

## EXPECTED OPERATIONS.

King's College Hospital.—The following operations are expected at this hospital to-day (Saturday), at 2 o'clock:—  
Necrosis of tibia; prolapsus ani; necrosis of sternum; fistula (two cases), by Mr. Fergusson. Lithotomy, Mr. Leo.

## DR. DE JONGH'S LIGHT-BROWN COD-LIVER OIL.

This pure, transparent, LIGHT-BROWN COD-LIVER OIL is invariably and carefully submitted to Chemical Analysis, and, to preclude any subsequent admixture or adulteration, is supplied ONLY in Bottles, capsuled and labelled with Dr. DE JONGH's Stamp and Signature, so that the Faculty may rely upon a genuine Medicine, and, so far as is possible, anticipate a uniform, regular, and certain result.

*Sole Consignees and Agents for the United Kingdom and the British Possessions,*

**Ansar, Harford, and Co., 77, Strand, London.**

HALF-PINTS (10 ounces) 2s. 6d. | PINTS (20 ounces) 4s. 9d. | QUARTS (40 ounces) 9s  
IMPERIAL MEASURE.

\*\* A LIBERAL DISCOUNT TO THE PROFESSION.

Now ready, Part IV. of

**The Grasses of Great Britain.** Illustrated by JOHN E. SOWERBY. Described by C. JOHNSON, Esq. To be complete in 30 Parts, at 1s.; uniform with "The Ferns of Great Britain." The Work will contain about 140 Coloured Plates. Prospectuses may be had through all Booksellers; or of the Publisher, John E. Sowerby, 3, Mead-place, Lambeth (S.)

**Sowerby's English Botany.** Second Edition. Reduced 25 per cent.

Twelve volumes, 2754 Plates, £20, cloth boards. Vols. I. to VII., Flowering Plants (1576 Plates), £10 10s., cloth boards.

**Sowerby's Ferns of Great Britain.** 49 Plates, cloth boards, full coloured, 27s.; partly coloured, 14s. plain, 6s. with coloured frontispiece.

**Sowerby's Fern Allies; flexible boards,** 31 Plates, full coloured, 18s.; partly coloured, 9s.

**British Poisonous Plants.** By C. JOHNSON, Esq., flexible boards, crown 8vo, with 28 Plates, full coloured, 7s.; plain, 5s.

John E. Sowerby, 3, Mead-place, Lambeth, S.

**The Artificial Tympanum for the**

Relief of Deafness, attended by loss or Injury of the Membrana Tympani, and for the Cure of Discharges from the Ear. The Invention of JAMES YEARSLEY, Esq., M.R.C.S. Eng., Surgeon to the Metropolitan Ear Infirmary, Sackville-street, etc. etc.

Superintendent of the Patent, Mr. CHARLES GREENE, to whom all communications should be addressed. Depot, *pro tempore*, 20, King William-street, Strand.

PRICE.—Silver Tube and a Month's Supply of Prepared Cottons, with Printed Directions, 2s. 6d.; sent by post, 2s. 8d. Prepared Cottons without the Silver Tube, 1s.; by post, 1s. 2d.

This invention has been Patented, not with a view to Profit, but to insure the transmission of Printed Directions with each Apparatus, for the guidance of the patient; and secondly, to prevent further piracy by the substitution of improper materials, which by constant failure, bring the principle of treatment involved in the invention into disrepute.

**J. Bradshaw, late Shoolbred**

and BRADSHAW, 34, JERMYN-STREET,  
Begs to call attention to the various improvements in Patent

ELASTIC STOCKINGS, BELTS,  
KNEE-CAPS, SOCKS,

and Ladies' and Gentlemen's SPINE SUPPORTERS. A new description of BELT, invaluable for prevention of Cholera, and the Cure of Rheumatism, Lumbago, etc.

N.B. Every description of INDIA-RUBBER BANDAGE, vulcanized on the newest principle. Directions for measurement sent by post.  
N.B. A liberal Discount to the Profession.  
A female to attend on ladies.

**James's Powder. — Physicians and**

other Medical Practitioners having complained of the frequent use of Antimonial Powder, instead of the genuine "James's Powder" proscribed, have represented to Messrs. Newbery, that the price of the powder has greatly led to this fraudulent practice, and has also greatly prevented the more general use of the powder. Messrs. Newbery have therefore yielded to the suggestions of the Profession, and have reduced the price; and, to secure the use of the genuine medicine, recommend that the same should be procured as prepared by Messrs. Newbery, from the only copy of the process left by Dr. James in his own handwriting, thus, "Fulv. Jacobi Ver." (Newbery's.) The price for dispensing will henceforth be reduced from 21s. to 9s. an ounce. The genuine has the name, "F. Newbery, 45, St. Paul's, London," engraved on the Government Stamp.

**Crosse and Blackwell, Purveyors in**

Ordinary to Her Majesty, respectfully invite attention to their PICKLES, Sauces, Tart Fruits, and other table delicacies, the whole of which are prepared with the most scrupulous attention to wholesomeness and purity. The practice of colouring pickles and tart-fruits by artificial means has been discontinued, and the whole of their manufactures are so prepared that they are not allowed to come in contact with any deleterious ingredient. A few of the articles most highly recommended are, Pickles and Tart Fruits of every description, Royal Table Sauce, Essence of Shrimps, Soho Sauce, Essence of Anchovies, Jams, Jellies, Orange Marmalade, Anchovy and Bloaters Pastes, Strasbourg and other Potted Meats, and Calf's Foot Jellies of various kinds for table use. C. and B. are also sole agents for M. Sayer's Sauces, Relish, and Aromatic Mustard; and for Carstairs' Sir Robert Peel's Sauce, and Payne's Royal Osborne Sauce. The above may be obtained of most respectable Sauce Vendors throughout the United Kingdom; and Wholesale of

CROSSE and BLACKWELL, 21, Soho-square.

**Recent Improvement by Mr. Jeffreys**

in the RESPIRATOR. J. E. PERCIVAL respectfully invites the attention of the Profession to an important improvement in the Oral Respirator, which, having a maximum warming power of no less than 40°, can be instantaneously reduced, even without being displaced, to any of five grades down to a minimum of about 15°, and vice versa. So that, in an atmosphere varying between 30° and 55°, air may be respired of one steady temperature of about 70°, or lower if desired.

The Profession are doubtless aware that the name Respirator is being assumed for various defective imitations. The RESPIRATOR may be had of the principal Chemists and Surgical Instrument Makers in town and country. Wholesale Office, 25, Bucklersbury, City. J. E. Percival, Manager.

By a small annual payment, Life Assurance secures the following provisions:—

1. Policies at death of husband, father, or son, so that widows and children are not left destitute.
2. Settlements secured in marriage contracts.
3. Endowments to children; so that funds are provided for apprenticeships, &c.
4. Security to creditors to provide against the death of their debtors.
5. Security to the debtors themselves; so that at death their estate or business is unincumbered by debt.
6. Capital to meet the loss entailed by the falling in of annuities or reversions.
7. Funds to meet renewals of leases at increased rents.
8. Sums of money payable to the assured themselves on attaining a certain age.

The attention of the Medical profession is called to the following scale of fees payable by the Company on business introduced by the medical attendant:—

Fee of £2 2s. for every assurance of £250 and upwards.  
Fee of £1 1s. for every assurance of £100;

and, in addition, a commission of 10 per cent. on the premium of the first year, and five per cent. on subsequent payments.

Prospectuses and proposal forms may be obtained on application to  
FREDERICK BIGG, Actuary and Secretary.

Persons about to Assure are invited to examine the peculiar features of this Society.

By the introduction of an important principle, provision has been made whereby a Policy-holder of three years' standing can continue his Policy even though he should be unable to pay the premium.

Loans granted on approved Securities combined with Life Assurance.

This Society remunerates Medical men for their Reports, and allows them Commissions upon all business they may influence direct to the Chief Office.

Prospectuses, Forms of Proposal, and every information may be obtained (post free) on application to the Secretary at the Chief Office, to whom applications for vacant Agencies may be addressed.

EDWIN H. GALSWORDTHY, Actuary.  
JOHN CAZENOVE, Secretary.

# Report of the Directors of the Clerical,

MEDICAL, and GENERAL LIFE ASSURANCE SOCIETY, presented at the Annual General Meeting, held at the Society's Office, No. 13, St. James's-square, London, Friday, November 27, 1852.

It will be in the recollection of the Proprietors, that, at Two Extraordinary General Meetings held on the 1st and 28th of January last, the period for holding the Annual Meetings was altered from March to November, in order that earlier publicity might be given to the state of the Society's affairs at the end of June, that being the period fixed by the Deed for the termination of each financial year. In consequence of this alteration no Meeting took place in March last, and it is therefore now the duty of the Directors to lay before this Meeting a statement of the transactions of the Society for the Two years ending June 30, 1852.

The number of New Policies issued within that period was 1097;  
The amount of Assurances was £305,300; and  
The New Premiums arising therefrom amount to £20,729 per annum.  
The Assurance Fund, notwithstanding the payment in cash of £25,384 as Bonus, since the declaration in January, has increased during the two years by no less a sum than £55,676.

From these facts it will be readily perceived, that during the period under notice, the progress of the Society has been in no degree retarded by the effects of the war, by the state of the money market, or by the active competition which has existed amongst kindred Institutions.

After the full and comprehensive statements made at the Extraordinary Meeting in January last, when the SIXTH BONUS was declared, the Directors feel that there is little further now to communicate; but they cannot refrain from mentioning that the Bonus then divided, which averaged 46 per cent. in Reversion, and 27 per cent. in Cash on the Premiums received since 1851, has given general satisfaction, and has tended materially to sustain and advance the high estimation in which the Society has been so long held by the Public.

An Account of the Proceedings at the last BONUS MEETING, setting forth the Assets and Liabilities of the Society, and also the FAVOURABLE POSITION IN WHICH PERSONS WHO NOW ASSURE will be placed, can be obtained on application.

GEORGE H. PINCKARD, Actuary.

GEORGE CUTCLIFFE, Assistant Actuary.

13, St. James's-square, London, S.W.

N.B.—A Fee of ONE GUINEA is paid to the MEDICAL ATTENDANTS of all Persons proposing to Assure.

# Broughams.—Kinder, M'Naught, and

SMITH, MANUFACTURERS, WORCESTER, beg respectfully to invite the attention of professional men to their improved Medical Broughams, as under:—

Width of Seat.	Weight.	Price.
3 ft. 5 in. .. ..	7½ cwt. .. ..	85 Guineas.
3 ft. 6 in. .. ..	8½ cwt. .. ..	95 Guineas.
3 ft. 7 in. .. ..	9 cwt. .. ..	100 Guineas.

The latter, including a segmental front, with seat for third person.

These Carriages are constructed, by the aid of machinery, of the best material, are of excellent workmanship, and particularly adapted to the wants of medical men, either in town or country. Drawings and other particulars forwarded on application.

# Tarrant's Bandage and Strengthening

PLASTER.—This Plaster, from the nature of the composition and the material on which it is spread, is adapted for a permanent bandage, as it neither produces irritation of the Skin, nor, when applied, does heat cause it to lose its adaptation to the part. Having these qualities, it is peculiarly valuable in the treatment of ulcerated legs, varicose veins, etc., where equal and constant support is required. Several of the most eminent Surgeons continue to use this Plaster in their practice, preferring it, in certain cases, to any other. It is well suited for exportation to, and use in, warm climates, the high temperature having less effect on it than on any other Plaster.

The Profession are referred to Messrs. Westwoods and Hopkins, Wholesale Druggists, Newgate-street, where the Plaster may be had in packets, containing three yards, for 2s. 6d.; or, spread upon skins of Chamois leather, at 3s. 6d.

Westwoods and Hopkins also call attention to the Compound Adhesive Plaster, for fractures and wounds; as likewise to their Concentrated Preparations, Essences, etc.

## ORIGINAL LECTURES.

## A COURSE OF CLINICAL LECTURES

ON

## DISEASES OF THE KIDNEY.

By GEORGE JOHNSON, M.D. F.R.C.P.

Physician to King's College Hospital.

## LECTURE II.

GENTLEMEN,—In my last Lecture I reminded you of certain facts relating to the minute structure of the kidney, which you will have constantly to remember while studying the pathology of that organ. I gave you a definition of Bright's disease. I told you that the primary seat of each form of the disease is in the gland-cells which line the uriniferous tubes; and I briefly alluded to two of the most frequent signs of Bright's disease—namely, an albuminous condition of the urine, and the appearance in that secretion of microscopic casts of the tubes of the kidney.

Albumen and tube-casts are not constantly present in the urine of patients suffering from Bright's disease. I shall hereafter show you, that in some forms and stages of that disease the urine contains no albumen, and that in some cases no tube-casts are visible; but it rarely happens that both these signs are simultaneously absent in cases of advancing renal degeneration.

Before directing your attention to the cases of Bright's disease which you have lately seen under treatment in the hospital, I purpose to give you some account of one which occurred out of doors. A brief consideration of this case will help you to understand those of which I shall afterwards have to speak to you.

Some time since I was asked to see a woman named Ann Furze, 64 years of age, living in the neighbourhood of the hospital, and supposed to be suffering from typhus fever. I found her in a state of half stupor, with a wild, distracted look, and a brown, dry tongue. The case certainly had very much the appearance of fever; but I learned from her attendants (the patient herself being unable to give me any account of her symptoms) that a few hours before I saw her she had been seized with a convulsive fit; then I ascertained that during the previous fortnight she had been suffering from intense headache, with occasional vomiting; further, that there had been some degree of dropsical swelling of the body, also that she had complained of pain in the back, and that the urine was scanty and high-coloured.

There was some slight puffiness of the face, but no other symptom of dropsy; the urine, however, contained a large amount of albumen.

It was now plain that the vomiting, the headache, and the

FIG. 4.

a. a. Tube-casts entangling renal epithelium and blood-corpuscles.

Vol. XXXVII. No. 955.—NEW SERIES, No. 394.

convulsions were the result of uræmic poisoning consequent on disease of the kidney. Then arose the important practical question, Was the kidney in an advanced and incurable stage of degeneration? or was the disease recent and acute, and, therefore, probably curable? A microscopical examination of the urine enabled me to give a satisfactory answer to this question. The urine deposited a copious sediment of uric acid, and it contained numerous tube-casts, which entangled entire cells of renal epithelium; similar epithelial cells were also scattered over the field of the microscope.

These appearances in the urine which I have now described, and which are represented in the drawings, are rarely seen in any cases of renal disease except those which are recent and acute.

This, then, was an example of what we are in the habit of calling *acute desquamative disease* of the kidney, the abundant desquamation of renal gland-cells being its most characteristic feature. Let me warn you against an error which has not unfrequently been committed—that of mistaking the pavement epithelium of the vagina and uterus for renal gland-cells. This form of epithelium is represented in the lower part of the circle (fig. 4 c), and you see that the cells differ from those of the kidney in their greater breadth and transparency, in being often clustered together in irregular patches, and never entangled in fibrinous tube-casts. These structures appearing, as they often do, in the urine of women, are indicative of vaginal or uterine leucorrhæa, and not of renal desquamation.

Returning now to my patient; having ascertained not only the existence of renal disease, but also its acute character and its probable curability, I was in a position to give a hopeful prognosis, and to direct the treatment. I prescribed cupping, to the extent of eight ounces, over the kidneys; gave a pill of calomel and colocynth, followed by a saline purgative, and directed only liquid food to be taken. The urine soon became more copious, and there was no return of convulsions; the vomiting and the headache ceased, and complete consciousness soon returned. In short, every symptom of disease gradually but completely disappeared, and the urine lost all trace of albumen.

Now, side by side with this case, let me place another which came under my care in the Hospital. In some respects the two cases are very similar, but there are some points of difference between them.

David Herbert, aged 45, a porter, of temperate habits, was admitted into Fisk Ward on the 20th September, 1863. When I saw him, on the second day after his admission, I found that the case was considered to be one of fever, and a stimulating plan of treatment had been commenced. The patient was lying in a state of semi-coma, unable to speak, the mouth half open, the tongue brown and dry. These symptoms would naturally suggest the idea of fever; I found, however, that there was no feverish heat of skin, that the pulse and respiration, which had been respectively only 80 and 18 on the day of his admission, were, at the time of my visit, only 85 and 20; and that there was no appearance of either rose spots or a mulberry rash on the skin. I thought the case had the physiognomy of uræmic poisoning, and having ascertained that no dropsy was present, I asked to see the urine, which on examination was found to contain a very large amount of albumen.

We had now made a great step towards a complete elucidation of the case. There could be little doubt that the brain-symptoms, the unconsciousness, etc., were the result of blood-poisoning through a defective secretion of urine. Then, as in the former case, there occurred this question—Had we to deal with a case of chronic Bright's disease in an advanced stage, or was the disease acute, and of recent origin? This question—of great interest to us and of vital import to our patient—a careful examination of the urine might perhaps enable us to answer.

The urine, as I said before, was abundantly albuminous, its sp. gr. 1022; it was rather high coloured and turbid, and it deposited a light coloured sediment, which contained numerous small waxy casts (similar to the smaller casts represented in fig. 3, p. 2.) with a considerable amount of pus. The pus was not moulded in the form of tube-casts, but scattered over the field of the microscope, or clustered in irregular masses. I may at once tell you that we afterwards ascertained the probable source of this pus to be the mucous membrane of the bladder. Disregarding the pus, then, as having no relation

to the renal disease, the small waxy casts without epithelial cells upon them indicated a non-desquamative condition of the kidney. An albumino-fibrinous exudation was being poured into the tubes of the kidney, but there was no epithelial desquamation as in the case of Furze, which I just now related to you.

Now this non-desquamative condition of the kidney, with a copious secretion of albumen, may occur as an acute or as a chronic affection, and it is often difficult, from an examination of the urine alone, to determine whether the disease is recent or of long standing. In the case of Herbert there was no oil in the casts, the kidney therefore had not passed into a state of fatty degeneration. This fact, and the complete absence of dropsy, were in favour of the disease being recent. A chronic, non-desquamative state of kidney, attended as it usually is with a scanty secretion of highly albuminous urine, is almost invariably associated with a greater or less degree of dropsy before it gives rise to other serious symptoms. This rule is not without exceptions, but practically it is an important rule to bear in mind.

After a consideration, then, of all the circumstances of this case of Herbert, although we were less confident as to the renal disease being of recent origin than we were in the case of the woman Furze, there was at least a great probability that the affection of the kidney was an acute and curable one; and it was obviously right to treat it as such. Accordingly I directed that six ounces of blood should be taken from the loins by cupping, and half a drachm of compound jalap-powder to be given every six hours. Milk diet. Beef-tea. The operation of cupping was found to be impracticable on account of his restless mobility, and twelve leeches were substituted.

He began to improve almost immediately. On the 23rd—the day after the change of treatment—the bowels had been freely opened, and he was sufficiently conscious to nod assent when a question was put to him in a loud voice. On the 26th, the report was, "Altogether much better, much more sensible; can slowly answer some simple questions; he still looks very heavy and stupid, but can be roused by sharp speaking. Tongue less dry and furred; pulse 60; bowels freely open. Has passed  $3\frac{1}{4}$  pints of urine during the last twenty-four hours, sp. gr. 1022; albumen less; microscopic character the same. The powder to be given only once a-day.

September 29.—He appears much better; can now give some account of himself, though he has to think and recollect himself before he can give an answer. He complains of headache; pulse 64. The urine is much less albuminous.

Quinæ disulph. gr. j., acid. sulph. dil.  $\mathfrak{m}$  x., aquæ,  $\mathfrak{z}$ j. ter die. Pil. colocynth. comp., gr. x., p. r. n.

From this date his progress was uninterrupted, and he left the hospital on the 31st of October. The urine at that time still contained a small quantity of pus, which rendered it opalescent by heat. No tube casts were visible, and from the report which he gave of having had occasional attacks of "gravel," it appeared highly probable that the mucous membrane of the bladder was the source of the pus.

The account which, after his recovery, he gave of the cause and commencement of his illness is not without interest. The following is the substance of it:—He had been in the employ of a grocer as a porter, receiving only six shillings a week as wages. He had lived badly, had been insufficiently clothed, and had frequently got wet feet. About three weeks before his admission he began to suffer from headache; he felt heavy and stupid, and his memory was impaired, so that when he went out with his parcels he could not remember what he had to do with them, or what money he should receive for them. He found that he could not walk steadily, and he often ran against passengers in the street. These symptoms continued and increased until the day of his admission. On the morning of that day he went out with his parcels as usual, but he was more stupid and forgetful than ever. His master seeing that he was very ill sent him home to bed, where he was soon afterwards found in a state of half-consciousness, and brought to the hospital.

In the history of this case we have an interesting and instructive illustration of gradually increasing oppression of the brain, produced by uræmic poisoning, consequent on acute disease of the kidney; and a gradual passing away of the cerebral symptoms when the kidney disease was removed, and the free secretion of urine was re-established.

You see that in each of the two cases which I have now detailed to you the disease had, at first, been mistaken for

fever, and I know of other cases of uræmic poisoning in which a similar error of diagnosis was made. You must be careful hereafter to avoid this mistake, for it is one likely to be attended with serious and even fatal mischief. The treatment which is usually successful in cases of acute renal disease, more especially free purging, would be very injurious in a case of typhoid fever; and, on the other hand, the treatment best suited for fever, including the administration of alcoholic stimulants, would be worse than useless in a case of acute Bright's disease, with threatened suppression of urine. With respect to this important point of practice, I trust that you will find that "forewarned is forearmed." Bear in mind the possibility of mistaking simple uræmia for typhus or typhoid fever, and you will probably avoid this serious error in diagnosis.

Before I conclude, let me direct your attention to a very important class of cases which you will certainly meet with in practice. It not unfrequently happens, that during the progress of typhus and typhoid fever, the urine contains one or more of the constituents of blood. The secretion may be simply albuminous in a greater or less degree, or it may contain a notable quantity of blood. A deep blood tinge of the urine is not likely to escape notice, but the urine may be very scanty and very albuminous, without any striking change of colour; and in such cases, if your attention has not been particularly directed to this circumstance in the natural history of fever, a very serious complication may be entirely overlooked, and therefore left without remedy. I shall probably have repeated opportunities of pointing out to you the complication of typhus and typhoid fever with renal congestion, a scanty secretion of albuminous urine, and the early occurrence of drowsiness passing into deep coma. In the meantime, bear in mind this practical advice. During the progress of typhus or typhoid fever make it a point to examine the urine either daily or every other day, and test it for albumen. This can be done with so slight an expenditure of time and labour that the neglect of it is inexcusable. If you find that the urine is becoming albuminous and at the same time scanty, be sure that serious head symptoms will speedily appear and give your prognosis accordingly; remembering, that, *ceteris paribus*, the danger is great in proportion to the scantiness of the secretion of urine and the amount of albumen; greater, too, when this complication occurs at an early period of the febrile disease than when the malady is more advanced.

With respect to the treatment of this acute renal disease occurring in connexion with continued fever, I would simply remark now, that in every case repeated dry-cupping in the loins is admissible and often very effectual. When the urine is very scanty, the albumen copious, and the drowsiness threatening, you may venture to abstract a few ounces of blood from the loins by the scarificator or by leeches, remembering that uræmic coma is more perilous than mere exhaustion, and that the relief of the renal congestion and an increased secretion of urine may be beneficially purchased at the expense of a few ounces of blood. Meanwhile the strength of the patient must be supported by liquid food and stimulants, according to the circumstances and symptoms of each case.

## LECTURES

ON

## THE ANATOMY, INJURIES, AND DISEASES OF THE HEAD,

DELIVERED IN THE

Theatre of the Royal College of Surgeons of England.

By PRESCOTT HEWETT,

Professor of Anatomy and Surgery to the College.

## ON FRACTURES OF THE SKULL.

### LECTURE I. (continued.)

A man, aged 28, was admitted into St. George's Hospital under the care of Mr. Cutler, in September, 1845, with a scalp wound laying bare the bone on the crown of the head. The accident was caused by a piece of an iron pipe, which, falling from a great height, had struck against some projection, and then came upon his head. He was stunned for about two minutes, but was quite sensible when he came to

the hospital. No fracture was discovered; there was, however, considerable bleeding from the nose, which continued upwards of an hour, and he also felt a good deal of pain in the neck, when the head was rotated. With the exception of some slight pain in the head, for which he was bled, everything appeared to be going on well, until the seventeenth day after the accident, when he was seized with nausea and pain in the head, accompanied by rigors. These symptoms were followed by drowsiness; then came gradually increasing insensibility; and, on the twenty-second day, complete paralysis of the right side of the body made its appearance. Under these circumstances, the crown of a large trephine was applied over the original seat of the injury. The operation was of no avail, and the patient died on the following day. At the examination after death, a lineary fracture was detected in the frontal bone. Starting from a slight separation of the sagittal suture, where the trephine had been applied, this fissure was traced through the frontal bone, perpendicularly down to the crista-galli. Yellow concrete lymph was found in the diploë, and patches of concrete lymph, with a small quantity of blood, existed in several places, between the bone and the dura-mater, along the line of the fracture. There was also extensive effusion of lymph and pus in the cavity of the arachnoid, as well as in the sub-arachnoid tissues, on the left side, and, corresponding to this, the grey substance of the brain was soft, and of a leaden hue. On the right side, patches of lymph were found in the cavity of the arachnoid only. The longitudinal sinus was filled with pus and lymph. The lungs were very much congested, and their tissue gave way easily under pressure. In the liver were large spots of secondary deposits. Nothing was observed about the other organs.

In the course of several years, this is the only case which has occurred at St. George's Hospital in which a fissure of the cranium was followed by symptoms of suppuration calling for the application of the trephine. One solitary case, and that one a compound fissure, in the course of ten years! What a commentary upon the surgical precepts of a few years back, when it was taught by one of the first men of the day, that "perforation is absolutely necessary in seven cases out of ten, of simple undepressed fractures of the skull." (a) How strange it appears to us that men, practising within our own time, should have been the first to establish, I ought to say revive, the rule of not trephining in these fissures of the skull, of not, in fact, using the trephine as a preventive of inflammation, which certainly does not occur in the great majority of cases of fissure of the skull! Just now, I said that this sound rule of practice, now so universally acted upon, was simply revived, and so no doubt it was, for it was clearly laid down some 250 years ago by François Martel, (b) of Lyons. And let me add that, at that period too, the bone was laid bare by a crucial incision, instead of scalping, which subsequently came so much into vogue, and that this same François Martel also recommends water as a dressing for scalp wounds.

The rule of practice which we have just been considering applies equally to those cases in which the fracture is committed without displacement of the fragments. What advantage could be gained by an operation in cases such as these? Evidently none, so long as there are no cerebral symptoms. As in fissures, so in comminuted fractures without displacement, the case must be carefully watched, and treated according to circumstances.

And now arises the question, What is to be done when the bone is not only broken, but driven in? In so wide a question as this, we had better, I think, confine our attention at first to those cases in which there are no immediate symptoms, looking only to the state of the broken bone, and to the symptoms which it may subsequently give rise to.

Are we in all cases of fracture with depression and without symptoms to elevate the bone? Such a question at once leads to another question, which, by most Surgeons of the present day, is considered to be one of vital importance. Is the fracture a simple or a compound one? Is there a wound leading down to the depressed bone? Upon the answer given to these questions turns the whole practice of some of the ablest and best of modern Surgeons. The existence, or non-existence of a wound communicating with the bone, becomes then, in these

fractures with depression, the main point, the one guiding principle in the practice of these Surgeons.

Led by their great experience, Sir Astley Cooper and Sir Benjamin Brodie laid it down as an axiom that intra-cranial suppuration does not often occur, so long as the depressed bone is covered over by its integuments. Hence the reason why these Surgeons so strongly urge the propriety of not interfering in such cases as these.

But let me add that the late Mr. Guthrie, whose opinions on this subject are entitled to great respect, taught, from the chair which I now have the honour of holding, that there is no more real danger in a case of fracture with depression, in which the scalp has been divided, than in one where the scalp has been bruised only, but not divided; and, in all cases in which a fracture with marked depression is known to exist in an adult, Mr. Guthrie thought the best practice was to divide the scalp, and ascertain the nature and extent of the depression.

Such, however, are not the opinions of the Surgeons now practising in our large Metropolitan Hospitals. Having lately inquired into the practice at these institutions, I find it to be an established rule that simple fractures of the skull, with depression and without symptoms, are to be left to themselves.

The depression may be so marked that we can easily detect it, and yet so long as there are no symptoms, all operative interference, of whatsoever kind, is carefully to be avoided.

It is a well-averred fact that in such a case the recovery may be, and often is, as rapid and as uninterrupted as if there had been no depression of the bone. But, at the same time, we should never forget that there always is danger lurking underneath a depression of this kind, and that a patient with such a depression may, at any subsequent period, be liable to mischief, always of a serious, and oftentimes of a fatal nature. Of this, the following is a well-marked example:—

A man, 40 years of age, was admitted into St. George's Hospital under the care of Mr. Tatum, in January 1844, with a small fluctuating tumour on the top of the head, at about the middle of the coronal suture. There was some rambling, but no paralysis. General headache was complained of, and this was accompanied by well-marked inflammatory symptoms denoting intra-cranial mischief. It appeared, from the wife's account, that this man, who was a coachman, had met with an accident some twelve months back, at which time he was thrown from his box, and pitched on his head. He remained in a state of insensibility for some little time, but had no further symptoms, with the exception of slight pain in the head occasionally, until within the last fortnight, when he began to suffer from constant pain in the head, and the other symptoms gradually made their appearance. Mr. Tatum opened the tumour on the head, and let out a small quantity of matter, after which it was discovered that a small piece of bone was driven in. A trephine was at once applied over the depressed bone; the external table came away first, but the internal table, which was broken up into small fragments, firmly adherent to the dura mater, and united to each other by a dense fibrous tissue, was removed with great difficulty. A large trephine was then applied in the immediate neighbourhood, as it was thought that there might be a more extensive fracture of the inner than of the outer table, but this did not prove to be the case. No matter was found between the bone and the dura mater, but there was a small quantity of it between the fragments of the depressed bone. The bone itself was exceedingly hard and thick, and the diploë very vascular. The dura mater under it was thickened and rough. The symptoms were not in the least relieved by the operation. A strict antiphlogistic treatment was at once adopted: bleeding, purging, and mercury, but all to no purpose. Within two days erysipelas made its appearance in the neighbourhood of the incision, and soon spread over the whole scalp, and upper part of the face. Death took place three days afterwards, and the body was examined on the following day. The calvaria was throughout most firmly adherent to the dura mater. The sutures were completely obliterated, and the bones exceedingly dense and heavy. All traces of the diploë had disappeared, and the osseous tissue was somewhat thicker than usual. The external table presented nothing remarkable where the crowns of the trephine had been applied; but the internal, in the neighbourhood of the smaller trephine-hole, presented a serrated edge, the surface of which was smooth, and bevelled off,

(a) Pott on Injuries of the Head, p. 130.

(b) Velpéau des Plaies de Tête, p. 9, 2e paradoxe.

proving that there had been a fracture of some standing. This portion of bone was not larger than a sixpence. There was no lineary fracture. On the internal surface of this calvaria were evident traces of long-continued chronic inflammation. There was no matter on the surface of the dura mater, neither was there any matter in the cavity of the arachnoid; but there was extensive effusion of lymph in the subarachnoid tissues covering the right hemisphere. The brain itself was healthy.

Here then we have a well-marked instance of the after-effects which sometimes arise from a depression of the skull. This patient, soon recovering from the immediate effects of the accident, went about his work as usual, and everything appeared to be going on favourably for a whole year, when symptoms of mischief about the head suddenly burst forth, and soon led to this man's death.

In this case the existence of the fracture was never even suspected. But, in all cases where a fracture of the skull with depression of bone is known to exist, it is the duty of the Surgeon clearly and emphatically to state to the patient the risks to which he for the future may be subjected.

Passing on now to the treatment of those cases of fracture with depression and a wound leading down to the bone, the compound fracture of Sir Astley Cooper, we come upon one of the most contested questions in surgery.

In the treatment of the fractures which we have hitherto had under consideration, we found that a tolerably uniform practice prevails in the present day. In the treatment of compound fracture of the skull with depression and without symptoms, we shall, however, find school arrayed against school, hospital against hospital, and even Surgeon against Surgeon in the wards of the same hospital. But how is this? Is it that the rules of practice which have been laid down have been hitherto drawn from a too limited field of experience? This may be, and to a certain extent is, perhaps, the case. But could the question be settled by a large number of cases taken from our metropolitan hospitals for instance, and divided into two sets, in each of which a similar plan of treatment had been pursued? I think not. And I must confess that to me the difficulties attending the drawing up of all such statistics appear to be insuperable. I know that it has been proposed to take from our hospitals a large number of apparently similar cases in which similar plans of treatment had been adopted, to compare the results, and then to decide. "Apparently similar cases." Here lies the difficulty. The nature of the accident, the local appearances about the skull, the general habits, granted that these were similar in both series—it is very easy to get thus far. But, what then of the more or less healthy condition of all the viscera in these patients? What of the condition of their blood? What of the atmospheric influences during the whole time of their illness? What of the state of the wards? What of the prevailing winds? What of the seasons? And are we, as Surgeons, to draw up statistics as to questions of operating, or not operating, and to take no account of such vital conditions as these? conditions, any one of which may be the means of baffling the best digested plans of treatment. Shall we ever get statistics taking all these points into consideration? Who are the men about our hospitals to undertake this truly Herculean task? The idea is simply Utopian. And, until we have such statistics, let it not be said that the question of operating, or of not operating, in compound fracture of the skull with depression and without symptoms, can be decided by our large hospitals.

What value are we to attach, then, as far as treatment is concerned, to the elaborate statistics published on injuries of the head? Take, for instance, the statistics of Blasius, of Leisnig, of Fritze, of A. Schwarz, of E. Walther,—of what value are the deductions drawn from these tables, as far as operation or no operation is concerned? In some respects, no doubt, these tables are very valuable; but, culled as the cases were, for the construction of these tables, from every locality, from many parts of the world, and from all kinds of authors, these tables are necessarily deficient in many of those details which, to Surgeons of the present day are all-important.

Again, take the statistics of Injuries of the Head from the Glasgow Infirmary, in which all the cases were, at any rate, in the same locality. What value are we to attach to these tables? Here, again, I fear that we shall not be able to derive all the advantages which so much labour ought to have given us. It is not that Dr. Laurie and Dr. King have

not made the best use they could of the materials which they had at hand; their tables are most elaborate, and, in many respects, very valuable. But so deficient are the details of the post-mortem appearances, that we have no means of judging of the general condition of the various viscera. Look to the dissections of the twenty-four cases of compound fracture operated upon. Details, it is true, are given as to the state of the head, but no mention whatsoever is made about any other part of the body, save in one single instance.

Now daily experience in our surgical wards proves but too plainly that the more or less healthy condition of the viscera exercises a most vital influence on all our accidents, and on all our operations; and if no account is given of the condition of the various organs of the body in the fatal cases of compound fracture of the skull examined in the Glasgow Infirmary, is not this a capital omission?

(To be continued.)

## ORIGINAL COMMUNICATIONS.

### THE PHYSIOGNOMY OF INSANITY.

By JOHN CONOLLY, M.D. D.C.L.

Consulting Physician to the Hanwell Asylum.

#### No. 2.—SUICIDAL MELANCHOLY.

A tendency to melancholy, or what is called the melancholic temperament—defined as meditative, serious, and often sad—is frequently associated with great mental qualities, and characterized by elevated views, allied, also, with fervent passions and strong attachments; intertwined with poetry, with meditations, perhaps visions; of large reforms in human policy and in religion, and with whatever is aspiring or sublime. By young persons of a studious and ambitious disposition this kind of temperament is sometimes, therefore, courted or affected, as a mark of superior ability. But the melancholy thus invited may prove a lingering and dangerous guest; and, both in youths and maidens, should be expelled, if possible, by active efforts. Without such resolution, ample food will be found, as years advance, to nourish the affection into malady. The emulative melancholy of the scholar, the fantastical melancholy of the musician, the melancholy of the politic courtier, the *nice* melancholy of the lady—even the lover's melancholy, of all these compounded—are not fictions of the great dramatist, but realities which offer their companionship at the age when the passions and the intellect begin to be active. Each offers its peculiar fascinations. Poetry of the noblest kind has invested melancholy with still more imposing grandeur; sometimes allying its sage and holy image with staid and stately wisdom, and looks commercing with the skies; and sometimes portraying, in powerful and seductive language, the merit of flying from mankind to some grove in the vast wilderness, or to the desert as a dwelling-place. But all these fancies and moods of the mind, if too often indulged in, tend one way—to a false estimate of realities, to inaction, to misery, and to madness.

For assuredly it may be said, without any kind of qualification, that there is no affliction so dreadful as a real morbid melancholy. The loss of wealth or rank, the severest invasions of bodily pain, and all shapes of human trial, would seem, to those often observant of melancholic patients, as dust in the balance against the weight of that woe which comprehends all woes, and is cheered by no hope, human or divine. Even very slight approaches to such a state, or the briefest experience of it, in those accustomed to notice the movements of their own minds, have something inexpressibly frightful in them. Transient misgivings, unaccountably mingled with vague terrors upspringing from the depths of the inexhaustible well of memory, shake the steadiest soul so strongly as to make it comprehensible how prolonged torture of the kind may overpower the natural love of life.

The Portrait accompanying the first paper of this series referred to the particular form of melancholia in which the mind is disposed to dwell on the mysteries of religion; and faculties inadequate to the task of comprehending such high

themes are vainly exerted to make plain what are matters not of mere reason, but of faith. In such a conflict, there is generally much risk that the over-tasked brain will suffer permanent injury; although in other varieties of melancholy, where the symptoms are equally severe, and even the tendency to suicide for a time incessant, the proportion of eventual recoveries is remarkable.

The course of events in such cases is generally this: Some bodily function becomes accidentally impaired; that of the stomach, or intestines, or liver,—or in women, of the uterus, or in either sex of the brain itself. Occasional depression of mind ensues, and gradually increases. The patient becomes inactive, abstracted, and silent, and all cheerful expression is banished from the countenance. Still very frequently these symptoms are scarcely deemed to imply anything within a doctor's province; until at length, on some dreadful morning, the patient first shows a determined tendency to self-destruction. After this the case is submitted to proper treatment; the disordered bodily function is carefully attended to, and measures are adopted of a nature to restore the lost energy of the brain. The attention of the patient is quietly attracted to new objects; first, by change of place and local circumstances, and afterward by travelling, although this is only beneficial at a later period. Some improvement gradually appears, which time confirms. The power of conversing is restored, and customary occupations and amusements are returned to. The face re-assumes occasionally its old expression, and gradually the gloomy look departs. It is at length felt that the constant watching, once indispensable to the patient's safety, may be relaxed, and then that it may be cautiously left off; very gradually, however, and very cautiously. Then the patient returns home, or takes a journey under the care of friends with benefit; and for a time the case is lost sight of. When it is almost forgotten, and sometimes, after many months, or even a year or two, the patient writes a letter reporting complete and continued restoration to mental comfort, and, if met in society, retains scarcely a trace of the attack in the manner, or conversation, or face.

These attacks, however, as well as other forms of mental malady are, it must ever be remembered, the frequent precursors of organic disease,—most frequently of the lungs, sometimes of the heart; in which case the symptoms continue obstinate, and not reason alone, but life is in peril.

The portrait accompanying the present paper represents a different variety of melancholia, but one of equal suffering to the patients, who are haunted, not by spiritual doubts, but by bodily fear, and chiefly of some terrible danger impending over themselves or their families; danger menaced by unknown enemies, above, about, or underneath.

It is evidently not the portrait of an educated or refined person, but a woman of the poorer ranks of life,—from which ranks our large crowded county asylums are filled. How people in such ranks contrived to live, and the kind of life they led before being sheltered there, is intimately known to few who attempt to write about them. They are usually even laborious, because want is ever in view. It is not the fear of difficulties and embarrassments which makes them rise early, and causes them to lie down exhausted with fatigue; it is the fear, nay the certainty, of starvation, if they are idle. So the best among them toil on until they rest in the grave; when, and not till when, their weary task is done. And the worst of them, too impatient of this lot, or tempted beyond their strength, deviate from the walks of industry into the side-paths of idleness and gin, of dissipation and sensuality, become instructed in thieving and other short ways to immediate gain, and die in their own manner. It is easy to moralize on these things, and virtuously to condemn; but God alone can judge such matters justly. If a man would try to do so, he must realise to himself an almost unfurnished home, and hungry children, and rent to pay, and scanty and coarse food day after day, and wretched clothing, giving poor protection against the "heat o' the sun" and "the tedious winter rages." He must fancy the state of his mind under the privation of all indulgences and all amusements, and in the utter absence of all comfortable recreation for mind or body. Who is there, more happily placed, who can estimate or even imagine the physiological results of all this combination of misery and privation? Imperfect digestion and nutrition; the impoverishment of the blood; the consequent deterioration of all the bodily tissues; the lowered character of the grey and white substances of the brain, involving the

limitation of the supply of nervous force to all parts of the frame, to those subserving physical offices, and to those of which the integrity is essential to the exercise of the mental and moral faculties;—all these are consequences which may not unreasonably be supposed to ensue to a greater or less extent. But the same causes continue to act in countless families, generation after generation, are transmitted and re-transmitted, and their effects accumulated and multiplied; so modifying the general development of the human being that we read even in the face of the bare-footed boy, in the streets of London, his woeful inheritance, and in the features and figure of the grown-up man or woman, in their speech and movement, their wretched physical history. Perhaps we may read something more printed there; the connexion of some, at least, of their faults, or vices, or crimes with the associated impoverishment, if it may be so called, of their higher faculties. We remark the ungainliness of the bodily shape and motion, and the pallor or the unhealthy suffusion of the face, and the ruggedness of the voice and language. With these marks of a degraded type we feel that there can hardly fail to be a corresponding mental limitation. With a total want of instruction there is, in fact, so unobservant a mind that they receive no knowledge from natural objects, and their natural theology is less advanced than that of the poor Indian who sees God in clouds or hears him in the wind. It is unnecessary to go further, now, into these sad particulars. But there is something unreasonable in expecting many excellences to flourish and Christian virtues to find existence in a soil so unprepared. Medical men, and those thoughtful persons, now happily not a few, who are devoting themselves to the advancement of social science, or the real science of living the life befitting so highly endowed a creature as man, do not ignore these painful facts, nor look unheeding upon them. To physicians who reflect on the cases coming under their care in the wards of our lunatic asylums for the poor, such facts are daily presented as material for serious thought.

In the general appearance of the patient, whose face and figure are copied in the photograph before me, there is something, surely, indicative of at least a few of the points which have been dwelt upon.

At first sight the portrait seems only that of a plain face, almost vulgar. Examined more closely, it becomes affecting. It speaks not of despondency merely, but of some horrible vision that has arisen in the mind. The hands are not only joined, as in ordinary examples of profound melancholy, but clasped, almost convulsively, finger within finger, with a muscular energy the expression of which the engraver has most ably caught from the faithful photograph. By this wonderful art the muscles also of the right forearm are depicted as almost in immediate action; and the whole attitude of the patient shows the preponderating muscular strain existing on the same side of the body. The right shoulder is advanced; the right knee is drawn up and pressed on the left. The inclination of the head to the right, the starting muscles on the left side of the neck, the excessive corrugation of the integuments of the forehead, all tell the same story of intense and painful emotion. All this energetic contraction seems to be produced by some fearful feeling. A further perusal of the face tells more than is revealed to a careless glance. The features are unrefined; but the wide and high head indicates intellectual qualities that cultivation might have improved; so as to control, perhaps, a now dominating ideality. The copious and dishevelled hair, which we feel sure must be black mingled with grey, is parted with no care, but straggles in sympathy with the tortured brain. Those many and curved wrinkles in the brow are not wrinkles of ordinary trouble. The raised and equally curved eyebrows; the large, melancholy, and uplifted eyes, declare that the sense is fixed on some image of fear, which no other eye can detect; and the intensity of the prevalent emotion is forcibly expressed in all the other parts of the face. The upper eyelids disappear; the lower are strongly depressed; the muscles of the cheeks and the corners of the mouth are drawn down, the lower lip being, as it were, spasmodically acted upon, showing nearly all the front teeth of the lower jaw. The chin has been scratched and scarred by her own finger-nails. The very ears seem starting forward. Everything bespeaks terror. You see that the suffering woman moves not; and that she holds little communion with those about her. Her whole aspect is in-

tensely sorrowful, as well as full of alarm. She is, indeed, abstracted from the common world of sorrow and suffering, but lives in a world of dread alone.

A professed physiognomist, to which title I myself lay no claim, would say that in the face of this poor woman, a certain superiority of character was manifest, although subdued by disease. The long square jaw, the developed chin, the large nose, the compressed and long upper lip, would furnish a text for a pupil of Lavater; and a phrenologist would draw clear conclusions from the configuration of the head. There may be something of fancy, but there is much more of truth in both of these sciences of observation, some acquaintance with which every one desirous to be an accurate observer ought to possess.

The actual history of this patient too well illustrated the miscellaneous remarks which have been offered to the reader. She was born of a mother on whom wretchedness had already done its work; and who was eccentric in mind, and eventually became paralysed. Her sole inheritance was poverty and labour, and a brain disposed to disease. In the portrait she looks old and worn, her real age being only 34. She was industrious, and led a correct life, and for a time managed to earn a living by straw-bonnet making. But this kind of labour is not very profitable, and, in order to ensure food and clothing, and the shelter of a roof, it was necessary for her to work fourteen hours a-day. No pleasures, no healthful exercise, were part of her lot. Her mind was of an anxious cast; and she ever felt, no doubt, that the intermission of toil for a day or two would entail difficulty upon her, or the prospect of starvation. What other fears haunted the poor creature we cannot say; but after her mind had quite given way, her often-repeated expressions were, "Oh! don't kill me, dear doctor!" "Don't let any one kill me!" At other times she would say, "I am too wicked to live!" and then she would humbly say that she had not committed any wickedness; but had always been an industrious and good girl. The dread, however, of being murdered grew stronger and stronger. She still worked on, with no salutary variety of any kind, until, with the inconsistency of insanity, she began to think she might escape the danger by destroying her own life. She made many and desperate attempts to do this; attempts only frustrated by the watchfulness of those about her, and by the arrangements of a well-ordered asylum. She would conceal bits of window glass and try to cut her throat; or tear off a strip of sheeting, and throw it quickly over one of the gas-burners in the gallery in order to hang herself. But vigilance saved her again and again from the first danger, and she was preserved from the second by the slight fixing of the burners, made with a prospective regard to such possibilities. The longest experience of the success of these and other attentions to the condition and propensities of the melancholic and suicidal, can yet scarcely make it intelligible how so very large a majority of these cases in asylums are safely managed throughout. If life can be preserved, the wish to die may leave the mind. So long as it remains, so long must the anxious solicitude of the attendants and the Physician continue. And still sometimes, after days and nights of care, a catastrophe may ensue. So fixed does the resolve of self-destruction remain in the poor distracted mind, and so preternatural an ingenuity is exerted in discovering the means of accomplishing it.

### ON THE TREATMENT OF INTERNAL PILES AND PROLAPSUS ANI BY NITRIC ACID.

By HENRY SMITH, F.R.C.S.

Surgeon to the Westminster General Dispensary, &c.

I have on one or two preceding occasions made some observations in the *Medical Times and Gazette*, on the treatment of diseased conditions of the rectum by the application of strong nitric acid. I have remarked that this practice was not sufficiently known among Medical men, that there was a dislike to its employment, and that consequently patients are frequently compelled to submit to a much more severe and dangerous proceeding, namely, the ligature. I am aware that this last-named method is one which is looked upon as

the most efficient plan of treatment by our best surgeons, and it is not to be denied that in the generality of instances the cure after ligature is effectual, but the operation is attended with a necessary confinement to bed, sometimes with severe suffering, and occasionally it is followed by death. Two fatal cases have been mentioned in this Journal during the last year, and I have heard of an instance, where a cavalry officer lately lost his life from this operation. Under these circumstances I think it is the duty of a surgeon to employ a remedy which is less hazardous if he has it in his power. The Profession doubtless dislike caustics in any shape, no matter whether they be used for destroying cancerous tumours, removing impermeable strictures, or curing piles, nevertheless the fact of this dislike existing does not prove anything against the utility of the remedy employed—not indiscriminately, as cancer curers and their protégés would do, but carefully and scientifically in properly selected cases. A strong prejudice, however, against caustic does exist among English surgeons, and this feeling is powerful enough to prevent the use of the agent. How difficult is it, for instance, to persuade even well-informed surgeons that the potassa fusa in inveterate strictures is anything but an unsurgical and useless agent, more adapted for the armamentarium of a Sepoy than for that of a British Surgeon! And yet those who know how and in what cases to apply the same can honestly testify that it is the most powerful and most useful means of opening up an obstructed urethra, and will enable the Surgeon in nineteen cases out of twenty to dispense with the use of the knife. So with nitric acid in the treatment of certain forms of internal piles, I believe that if properly used it will obviate in a large proportion of cases any severe operation. The following is an instance of its beneficial employment in prolapsus ani.

Mr. S—, aged 59, applied to me, March 3. He was in excellent health, but had suffered several years from a prolapsed gut. It always descends when he goes to stool, and generally when he walks out. On examination I found a considerable protrusion of the mucous membrane of the rectum. He has, in consequence, suffered lately from great irritation of the bladder, and has had complete retention of urine. I recommended the patient to use an injection of oak bark.

March 9th.—The gut is much prolapsed, and the patient has suffered greatly from irritation of the bladder. I applied nitric acid very freely, and having well oiled the parts returned them.

12.—The gut does not come down so much, and on examination to-day, it is difficult for him to protrude even a small portion. I applied the acid again.

20th.—I have applied the acid once since the last report, and he has called upon me to say he is quite well, and to express his gratitude for relief from sufferings which have troubled him for years.

In such a case as the foregoing the relief given by the application of nitric acid is striking; but there is another class of cases in which the benefit afforded is equally remarkable. I refer to those instances of internal piles when there has been more or less hæmorrhage for some time.

Mr. A., aged 23, sent to me by Dr. Beaman.

May 21.—He is in a weak state of health, and presents the appearance of one who has lost much blood: has been subject to piles for three years; they protrude when at stool, and he has every day during the last three months lost a large quantity of blood. On examination I found the mucous membrane of the lower part of the rectum in an unhealthy condition, and a large hæmorrhoidal excrescence protruding. I applied the nitric pretty freely.

25th.—Much the same; the bleeding has not ceased; the hæmorrhoid still protrudes. I made the patient sit over some hot water for some time, and when the piles were thoroughly protruded, I applied the acid freely.

28th.—A good deal of irritation was produced by the acid for several hours, but it gradually went off, and on examination there is no protrusion.

June 1.—This patient is very much improved. There has hardly been any bleeding or protrusion. I applied the acid slightly to the diseased part of the gut which could be brought into view.

6th.—He feels quite well, and has no protrusion of the gut even while at stool.

Mr. B., aged 29, also sent by Dr. Beaman.

October 6.—States that he had been troubled with piles for

two years, and that during the last six months he had suffered daily from bleeding, which was increased by horse exercise, to which he is much addicted.

The day before I saw him he had consulted an eminent Surgeon, who requested him to come to his house on the following day, and remain sitting over hot-water so that the gut might be protruded; but the patient fearing that an operation would be performed declined. I advised the gentleman to take a dose of castor-oil on the evening of the 7th, and to come to me on the 8th; on which day a highly vascular and thickened hæmorrhoidal mass was protruded; I applied nitric acid freely to it, and returned it within the sphincter.

9th.—He sent for me to his residence to-day. I found him in considerable pain: the diseased part had descended outside the sphincter, and the surrounding textures were much swollen. I returned the piles, ordered him to lie in bed for a few hours, and recommended hot fomentations and an opiate.

13th.—The patient went into the country until to-day: he has scarcely any bleeding: he took castor-oil before coming, and I applied nitric acid to the portion of the diseased bowel which was protruded.

20th.—The patient scarcely complains of anything, except a very slight bleeding when at the closet. There is now no protrusion. I had slightly used the acid on the 15th. To-day I examined with the speculum, and touched that part of the gut which seemed in an unhealthy state.

24th.—This gentleman suffers nothing from pain or protrusion even when at stool; but I examined with the speculum again, and applied the acid as there was some slight bleeding. I recommended the use of an injection of two grains of sulphate of iron to an ounce of water, into the rectum twice a day. I learned afterwards from Dr. Beaman that this gentleman was quite well, and ardently enjoying his favourite pursuit of hunting.

This instance illustrates in a particular manner the advantages of nitric acid; for here was a young and healthy man, passionately fond of field sports, and would brook no control, who was very anxious to get rid of his disease, but would not submit to an operation which would confine him to bed for several days, (I may also mention that he had heard of the death of the cavalry officer before alluded to;) I could, however, offer him a means of cure which would not lay him up, or prove dangerous. It is true that the very free use of the acid did confine him to bed for a few hours. This accident cannot always be avoided, but it has not occurred more than two or three times in my hands. There is one other point in connexion with the use of the agent, which this case also illustrates, viz. the amount of pain produced when the acid is applied through the speculum. On both occasions on which I used it the patient actually asked me after the mucous membrane had been freely touched, whether it had been applied or not. In fact he complained more of the introduction of the speculum, although a small one.

It is most important in the treatment of diseases of the rectum by nitric acid that the cases should be selected, otherwise the surgeon will be disappointed in the result, and the patient will be rendered worse than he was before. It is in those cases of internal piles, where the diseased texture is only of moderate extent, has a broad base, and presents a very vascular appearance, as though the excrescence was composed chiefly of minute arterial branches, that the acid will prove speedily and effectually serviceable: when, however, the hæmorrhoidal excrescences are very large and of a blue appearance, mainly consisting of venous ramifications, nitric acid should not be applied; neither should it be applied while a patient is suffering from what is called an acute attack of piles. I was unwise enough to use it in a case of this kind not long since, and although I believe the patient may have been ultimately benefited, great temporary distress was produced, and undeserved blame was thrown upon the remedy.

In cases of prolapsus ani of considerable size, when there is not a complication of large or several piles, and when the mucous membrane is simply thickened and relaxed, this remedy will be eminently serviceable. I have by means of it lately relieved a gentleman of the necessity of wearing a pessary, which he had done for years, being afraid to undergo a cutting or tying operation; and being ignorant of the efficacy of nitric acid in such cases until he had his attention called to one of my papers in the *Medical Times*. I have very recently been attending for another complaint an old

gentleman, who has for many years worn a pessary for a prolapsus as big as my fist, and who will not permit any operation. Here, however, nitric acid would I fear not be applicable.

Caroline-street, Bedford-square,

## TWO CASES OF REMOVAL OF STRUMOUS ASTRAGALUS, AND ARTICULAR END OF THE TIBIA, WITH PORTIONS OF CONTIGUOUS BONES.

By P. C. PRICE, Esq.

Junior Surgeon to the Great Northern Hospital,  
Surgeon to the Metropolitan Infirmary for Scrofulous Children at  
Margate, &c.

My colleague, Mr. Statham, reports, in the *Medical Times and Gazette*, of November 14th, an instance in which he has removed the astragalus with success, and alludes to other cases which have fallen under his own immediate notice. I have on two occasions resorted to this proceeding, and subjoin a short history of each case with some remarks.

Case 1.—George G., aged 8, of decidedly strumous constitution, was admitted under my care at Margate, in June, 1856, with extensive disease of the right astragalus, and disorganization of the ankle-joint. Arriving from London in a very delicate and precarious state of health, the foot was merely supported by means of a splint, and constitutional treatment insisted upon. By August, however, he had so much improved in condition, that it became advisable to turn more direct attention to the local affection. The following account of the condition of the ankle and contiguous parts I select from my note-book.

August 8.—The right ankle articulation is destroyed, and the grating of exposed surfaces clearly evident. On the outer side of the joint, in front of the external malleolus, two fistulous openings exist, through which sanious fluid, mixed with carious *débris* of bone, constantly flows. A probe introduced through these openings falls upon the decayed astragalus, and passing freely upwards shows the articular end of the tibia to be bared, in part, of its cartilage, and the lower portion of the fibula to be in the same condition. There is also evidence of mischief in the front of the astragalus, and probably of the cuboid bone. On the same day, the boy being placed under chloroform, the fistulous openings were sufficiently enlarged so as to admit an examination by the finger. The decayed astragalus was so altered and softened that it was easily broken down. By means of the gouge and curved cutting pliers, the entire bone was removed piecemeal, together with the articular end of the tibia, not including the internal malleolus. Portions of the os calcis, and the greater part of the cuboid bone, were also taken away. The end of the fibula was likewise removed in part. The cavity resulting from this extensive removal was filled with lint, and a splint of gutta serena fitted to the under and inner part of the leg and foot. There was little or no bleeding. On examining the portions thus removed it was apparent that the bones affected had been involved with strumous caries, but where the mischief had commenced is doubtful. In the treatment of the wound poultices were applied, and the limb maintained at perfect rest; the cavity being day by day, when suppuration had commenced, duly cleansed and refilled with plugs of lint. The reparative process advanced with such rapidity that towards the end of September consolidation had considerably progressed.

December 5th.—The soft tissues have greatly contracted, the foot is more symmetrical in shape, and the amount of new material appears more condensed, admitting considerable pressure to be applied with impunity. For some months the part continued to improve, but little use of the foot was allowed: subsequently, however, some swelling took place on the inner side of the ankle, which gave suspicion to the recurrence of disease. The part became more and more painful, till the skin ulcerated, and gave escape to some unhealthy discharge, mingled with *débris* of bone. The application of the gouge gave relief, by removing some softened and carious-looking bone.

November 9th, 1857.—The lad has a very tolerable foot, although there exists some slight swelling on the inner side of the ankle. There is little or no motion between the foot

and the tibia. The tibia is somewhat distorted, owing to a tendency to rickets, which gives an awkward appearance to the lad's gait. Some slight alteration to the instep of his ordinary boot will, I hope, enable him to retain with usefulness a member which has, on many occasions, been removed for a less amount of disease.

*Case 2.*—Francis B., aged 15, a highly strumous lad, a native of London, was sent to Margate in the summer of 1856, with extensive disease of the left ankle-joint.

August 18, 1856.—An examination, under chloroform, afforded evidence of complete destruction of the articulation. Fistulous openings on the outer side of the ankle freely communicated with carious bone in all directions. By carrying a curved incision through these fistulous openings, along the front of the external malleolus, sufficient room was obtained for a free use of the gouge and bone-pliers. By means of these instruments the entire astragalus, the articular end of the tibia, and the posterior surface of the cuboid bone, with a portion of the external malleolus, were removed. At the same time some disease of the two external metatarsal bones was taken away. Little blood was lost; the wound being filled with lint, was placed on a splint. Suppuration commenced in a few days, and by keeping up the general health reparation rapidly took place. In the course of a few weeks the granulations of new bone appeared firm and healthy, and by the middle of October union of considerable firmness had united the foot to the leg.

During the time nature was making such admirable endeavours in this locality, disease was infiltrating among the bones of the front of the foot, and an acute abscess was laying bare the fibula, and extending into the muscular coverings of the leg.

These untoward circumstances, unfortunately, demanded removal of the limb in the middle of the leg, which was resorted to on Nov. 4, 1856. On making a longitudinal section through the tibia and the new material that had taken the place of the astragalus, complete union was found to have resulted. The new product was bone of considerable density, and was apparently thrown out in greater proportion from the end of the tibia. The ankylosis would in time have been complete. The boy made an excellent recovery from the operation.

To my brother, Mr. W. Price, who had the daily charge of these cases, I am much indebted.

*Observations.*—Strumous disease of the ankle-joint, involving the astragalus, is an affection by no means uncommon, especially in children, and in many instances, I believe, commences in the articulation between the astragalus and os calcis. There can be no doubt that oftentimes the entire disease can be taken away without sacrificing the foot, and that the operation for removal is one by no means so difficult as might at first be supposed. Moreau recommends the incision to be made along the posterior margins of the tibia and fibula, and two transverse cuts as far as the anterior tibial tendon on the inner, and that of the third peroneal tendon on the outer side. In cases corresponding to the two I have related, where fistulous openings exist, and the carious state of the structures entering into the formation of the ankle can be surmised with some degree of accuracy, I believe the plan I resorted to on each occasion to be the most advantageous. While acting as dresser in the wards of King's College Hospital to Mr. Fergusson, I remember seeing a case treated in the same way, and the simplicity of the operation, with its complete success, made such a favourable impression upon me at the time, that I determined to adopt the same proceeding when occasion should present.

The gouge and curved bone-pliers have now become such indispensable instruments in the hands of the Surgeon when dealing with disease of bone, that they have necessitated many improvements in what is commonly known as "bone surgery."

With regard to the first case, it must be looked upon as highly satisfactory; and although the foot for some months has been a useless member, there is little doubt that an excellent cure will result, provided no relapse takes place. Had I not adopted this proceeding, the foot might have been removed at the ankle-joint; but I very much doubt, from all I have seen of this operation, if the patient would have been enabled at the present time to have made use of his stump as a means of progression. The superiority of the course I followed over amputation through the leg cannot for a moment

be doubted; for should disease recur in any portion of the foot, removal of the limb can then be adopted if necessary. In the treatment of the limb rest was enjoined, a splint keeping the foot in a suitable position, and preventing, by any undue motion, the liability of the disease to extend to neighbouring structures, supposing such tendency to exist. Doubtless some degree of movement between the foot and the leg is advantageous; but it is all imperative to obtain a firm and suitable support for the body.

Two operations were necessary before the disease could be considered as eradicated; and now it is not improbable that assistance may be again needed to remove some little carious spots; yet such repetition does not militate against a judicious and humane attempt to do the best for the unfortunate patient.

In the second case the operation was resorted to, owing to the patient refusing to lose his foot. Disease among the metatarsal bones foreshadowed the likely termination of the case; but had not mischief subsequently arisen in the lower portion of the leg, I should have resorted to a partial amputation of the foot, feeling assured that the new material, as appeared after removal of the limb, would have in time afforded an admirable support, and have enabled the patient to boast, perhaps, of a more useful stump than if the covering had been taken from the heel. The termination of these cases will in future induce me to have recourse to the above proceeding, even in instances in which the chance of success is not very promising, and more especially as the risk attending such an operation is slight, and in no way interferes with a subsequent resort to the knife if necessitated.

Green-street, Grosvenor-square.

## THE LONDON PRACTICE OF MEDICINE AND SURGERY.

### THE CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST.

#### ILLUSTRATIONS OF THE TREATMENT OF THROAT AFFECTIONS.

(Cases under the care of Drs. PEACOCK, BENNETT, and BIRKETT.)

"A form of hoarseness is frequently observed in growing boys or girls which assumes a very chronic character, and often resists for a long time almost every sort of treatment. A boy gets cold, followed by sore throat and feverish symptoms, which may last for a few days and then disappear under the use of aperient medicine, or perhaps without any interference on the part of the parents or the physician. The feverishness and soreness of the throat subside, but the hoarseness remains, and the boy can only speak in whispers. This condition may last for weeks and even months, without any other symptoms whatever; the patient has no cough or difficulty of breathing; his appetite is good; sleep and digestion natural, and there is no appearance of emaciation. The only thing amiss with him is the impairment of voice, and this continues so long that it gives rise to a considerable degree of anxiety on the part of his parents. When you examine the fauces you find no appearance of inflammation in the mucous membrane, and there is no superficial or deep-seated tenderness in the region of the larynx." Such is the graphic description given by Dr. Graves(a) of a class of cases very well marked in character, which, however, are not very frequently met with in English practice. The following are good examples of the affection.

*Case 1.*—Chronic aphonia, etc. of four months' duration.—Treatment by tonics, and the weekly topical application of nitrate of silver.—Recovery in four months.—Benjamin Green, aged 6, a pale, but not otherwise unhealthy-looking boy, was admitted on September 15, 1853, under the care of Dr. Risdon Bennett. He had been aphonic, with hoarseness on attempting to speak loudly, for four months. There had been some cough, but no serious symptoms whatever. He had already had a variety of treatment without benefit. Nothing beyond a mamillated condition of the posterior pharynx was discovered

(a) Clinical Lectures on Medicine, vol. ii. pp. 1, 2.

on inspection of the throat. Dr. Bennett prescribed a draught containing quinine and iron, and directed a solution of nitrate of silver (ʒj. ad ʒj.) to be applied to the larynx by means of the probang. The lad was very patient, and permitted of this being effectually done. It was repeated once a week, with two omissions, up to December 1, when the note states, "Can now speak pretty clearly." On December 15 the note is, "He certainly does not speak so clearly as last time. He has missed attending for a fortnight." The solution was again applied, and the mixture steadily continued. On January 26 the application was made for the last time (the fifteenth) and the note then taken is, "When at home he is stated to speak quite clearly, but when excited he occasionally partially loses his voice. The posterior pharynx is still mamillated, and its mucous membrane looks as if thickened." On February 9 the note was, "Can shout loudly," and on the 23rd he was discharged quite well. The mixture—half a grain of quinine and a grain of sulphate of iron—three times a day, had been continued the whole time.

**Case 2.—Aphonia of four years' standing.—Treatment by counter-irritants, mercurials, etc.—Some benefit.**—Jane Doughty, aged 9, was admitted on August 1, 1853. The following are Dr. Bennett's notes, dictated at the time. "Aphonia of four years' standing. General health fair; appetite good; no cough; mucous membrane of throat flabby, and tonsils rather large. Tongue clean, and pulse quiet. The aphonia is stated to have commenced as hoarseness, and to have been several weeks before it was complete. For four years it has been as at present, and without any intermissions." Ordered to have the throat painted externally with a strong solution of iodine, and to take three times a-day quinine and iron in infusion of cascarrilla.

August 8.—The throat has been made very sore indeed by the iodine, but there has been no material improvement of the voice in consequence. Her mother states, however, that she has slept with much less of wheezing noise in the throat than she formerly did.

The mixture was continued, and on the 22nd the iodine paint was again applied.

29th.—The improvement had been very slight hitherto, and Dr. Bennett now ordered a pill containing four grains of the compound squill pill, one of blue, and a sixth of the potassio-tartrate of antimony, to be given every night: the mixture to be continued.

Oct. 3.—Slow but decided improvement has resulted. The remedies are now to be changed to a mixture containing two grains of the iodide of potassium to half an ounce of the infusion of cascarrilla, given with two teaspoonfuls of cod-liver oil three times a-day. The solution of nitrate of silver (ʒj. ad ʒj.) to be applied every week to the larynx.

We are unable to give the final result of this case, as the girl ceased to attend after the second application of the caustic, probably on account of her extreme dislike to it. Had it been steadily persevered with, probably the same degree of benefit which resulted in the preceding case might have eventually been obtained; but on account of the very protracted duration of the disease, a long treatment would no doubt have been requisite.

**Case 3.—Chronic hoarseness and aphonia of three months' duration.—Cure by two applications of the nitrate of silver solution.**—Caroline Twig, aged 14, was admitted under Dr. Bennett's care on Jan. 12, 1854. She was hoarse and almost aphonic, the statement being that she had been so without intermission ever since a cold, three months ago. She was a healthy-looking girl, and had no symptoms of pulmonary disease. The cough was but slight. Dr. Bennett prescribed the compound cascarrilla mixture, to be taken three times daily, and an aloes and myrrh pill to be taken every night at bed-time. These were continued for three weeks without any benefit, and on Feb. 2nd, accordingly, resort to the nitrate of silver solution was directed. This (of the same strength as in the two previous cases), was freely applied on two occasions, and with such marked advantage, that on Feb. 16th, the note states, "Voice much better, almost clear." She continued the cascarrilla mixture a month longer, and having had no relapse, was discharged on April 6th, quite well in every respect.

**Comments.**—We have selected the second of the three preceding cases, on account of its affording an extreme example of the chronic character of this affection; and the first and

third, because they well illustrate the most effectual method of its treatment. The success in the last was unusually rapid; and the first is perhaps a better example of the average. Dr. Graves, although stating most correctly respecting its pathology, that "it depends on a relaxed and weakened state of the chordæ vocales, and perhaps the muscles of the larynx, the result of inflammation of an exceedingly chronic character," does not appear to have ever had recourse to topical applications for the cure of this affection. He advises gargles—which, by the way, children can rarely be got to use efficiently, and which, ever so well employed, have but little action on the larynx—and counter-irritants to the throat. The experience of the Chest Hospital is most decidedly in favour of the nitrate of silver solution as the one efficient means of treatment; and we believe this is the general result at which most physicians who have had extended opportunities in this specialty have arrived. At the same time tonics, as quinine and iron, should be administered, and particular precautions should be taken to protect the throat externally. The supervision of acute symptoms is always to be feared, but more especially if the patient be under the age of six, and if the disease have not lasted very long. Hoarseness in a young child is always an alarming symptom, and the parents of the patient should always be forewarned that croup may at any time suddenly come on. (a) If any alarming aggravations have ever occurred, it will be well to act upon Dr. Graves's statement, that "in all obstinate cases the sheet-anchor is mercury exhibited internally, and by means of inhaling the fumes of hydrargyrum cum creta. In general, it is necessary to continue the mercurials until the mouth is slightly touched, when the hoarseness will be found to yield." Mere "obstinacy" would not, however, to our minds, indicate the propriety of resort to mercury, and the "sheet-anchor," according to modern experience, in all cases not attended by threatening symptoms, is indicated above. We fully agree with Dr. Graves that no good results are ever obtained from "leeches, antiphlogistics, or low diet."

## THE "GREAT NORTHERN" HOSPITAL.

### DISEASE FOLLOWED BY FRACTURE OF THE CLAVICLE—OPERATION—RECOVERY.

(Under the care of Mr. GAY.)

W. B., aged 34, was admitted in October. He states that eight months ago he consulted Mr. Gay for a chronic abscess over the clavicle, and towards its acromial extremity, which was discharging through two sinuses, situated about an inch from each other. Mr. Gay laid the sinuses open, and searched for dead bone, but, as the man states, without being able to find a trace of any. The wound healed; but the man was unable to use his arm in his trade, that of a carpenter. On the 7th of October, while fastening a lock on a door, he felt as though he had received a sharp blow on the bone, the arm dropped, and as he became sensible of some change having taken place in its condition he applied to a neighbouring Surgeon, who told him the bone had been broken. Matter formed in the seat of the injury, and was discharging itself through one of the old sinuses when Mr. Gay saw him on the 16th. There was then considerable thickening around, but especially along a portion of the upper edge of the bone, where several small collections of matter had formed. This thickening made it difficult to ascertain the relative position of the two portions; and had so far fixed them that, although considerable force was used, the fracture could not be detected. A probe discovered denuded, and to appearance dead bone for some distance along the course of the shaft; and at one point, about an inch and a quarter from the acro-

(a) The present may not be an unsuitable place to ask attention to a plan of treatment of croup in its initial stage first recommended by Dr. Lehman, of Forgan, and which has received a most emphatic imprimatur from Dr. Graves. It has not yet become so widely known in this country as it deserves to be. It consists in the application of sponges squeezed out of water, as hot as can possibly be borne, to the throat of the little patient. They should be frequently repeated during from ten to twenty minutes, until a vivid redness of the skin of the whole throat is produced. It is stated that the most alarming symptoms will often wholly disappear under this simple plan of treatment. In all cases of hoarseness in young children the parents of the child should be instructed to have immediate recourse to it, in the event of any delay in procuring medical attendance occurring. It is of course curative only in the very earliest stage.

mion, it sank, as it were, into, and even through the cylinder. Mr. Savory and Mr. Statham concurred with Mr. Gay in thinking that a portion of the shaft of the clavicle had become necrosed; but could not make out satisfactorily the existence of fracture.

Mr. Gay accordingly laid the bone bare by a crucial incision, and dissected back the flaps, when it was found in the following state. The bone had been fractured. The acromial—the shorter—portion presented at its extremity a smooth surface, as though the body had been sawn through somewhat obliquely, covered with velvety granulations; while the distal extremity of the sternal portion had the appearance of having been extensively splintered; the splintered prolongation having, so far as the outer laminae of the bone were concerned, become necrosed. As Mr. Gay was not prepared for this discovery, he contented himself with cutting off the ends of the fragments, placing them in apposition, and confining them in position by proper bandages and pads. The wound healed readily, leaving one sinus, however, through which spiculae, or rather small, thin, osseous plates discharged themselves for several weeks. The sternal fragment did not remain quite in the position in which it was placed; but notwithstanding this the two ends became firmly united, and the man, seen by Mr. Gay within the past week, has recovered the use of his arm, with almost its primal amount of strength and variety of movement.

Mr. Gay has some difficulty in arriving at any satisfactory opinion as to the origin and course of this obscure but interesting case. It was deemed necrosis; but an exposure of the bone proved this view to be incorrect; indeed the cases of idiopathic necrosis of the clavicle would tend to show that necrosis of a small portion of the shaft of that bone is very rare; and this owing to the fact that the clavicle, unlike long bones generally, has but one centre of ossification. There were certainly no signs of caries. The bone had been severed through; one portion had retained its health. Any rough points that might have existed after the disunion had been absorbed; and in default of reunion the extremity had become precisely what the extremities of bones after amputation usually become. The extremity of the other fragment had, however, not been splintered by the fracture; but had assumed the appearance of having been splintered by some diseased action which had been going on within or around it. The necrosis of the external table was due simply, Mr. Gay thinks, to its having been constantly exposed to the action of the secretions; and the want of evidence of either caries or necrosis in the inner laminae and osseous tissue, (for the tissue had become hardened,) shows that neither of these affections had given rise to the loss of bony matter, and the strange shape which the remaining portion of the bone had assumed. Setting aside these hypotheses therefore as untenable, Mr. Gay could only suggest that the bone at the seat of separation had become the nidus of an acephalo-cyst; and that the peculiar condition, and almost spontaneous fracture of the bone were due to the absorption which attended the ravages of these cystic parasites.

## HOSPITAL NOTES.

### SUPPURATION OF THE EYE-BALL IN CONNEXION WITH GOUT.

THERE is at present a poor man attending Mr. Critchett's out-patient clinique at the Moorfields Hospital, in whom suppuration of the globe has followed repeated attacks of gouty inflammation. He is of very cachectic appearance, and of 58 years of age. His father was liable to gout, and for the last twenty-three years he has himself suffered from it, generally twice a year. Formerly it used to attack his feet, but for the last five years it has confined itself to the hands. The joints of the fingers are much thickened and crippled by deposit. Five years ago the right eye was first attacked, and in the course of repeated inflammations during the three following years, it was so far damaged that there remained but the merest perception of light. In this condition it remained quiescent for two years, when the acute and destructive attack set in. He was admitted under Mr. Critchett's care on December 4, the affection having then lasted three weeks, and the globe having already suppurated. The sclerotic gave way on its outer side, and about three weeks later the lens escaped. The inflamma-

tion was most intense, the lids being very much swollen, and of almost livid redness. Colchicum and alteratives were first used, and subsequently quinine. The globe has now partially collapsed, and the effects of the attack are slowly subsiding. Gouty iritis is by no means a rare affection, but for suppuration of the globe to occur in connexion with the arthritic cachexia is, we suspect, extremely unusual.

### RULES RESPECTING THE TREATMENT OF PRIMARY SYPHILIS.

It seems to be now pretty generally acknowledged in Hospital practice that mercury should be given only in those cases in which the chancre presents marked induration, and that in all others secondary symptoms should be waited for before having recourse to specific treatment. In a large majority of sores not attended by induration, no constitutional phenomena will follow; and to discriminate between those likely to be so followed and the harmless class is admitted to be impossible. There is, therefore, no alternative, except we would give mercury very often unnecessarily, but to wait in these cases until the real nature of the affection shall have been made manifest. In the non-indurated class local stimulants, as sulphate of copper, lunar caustic, or the acid nitrate of mercury, are the old and still favourite remedies. If the chancre be seen within a week of its origin, whether induration have already commenced or not, we believe most surgeons would destroy it freely either by nitric acid or some other caustic.

### "ONYCHIA MALIGNA," USUALLY A SYPHILITIC DISEASE.

Two very instructive cases of the so-called "onychia maligna" have recently been treated by Mr. Hutchinson at the Metropolitan Free Hospital. In the first of the cases referred to a girl, aged 9, was sent by the Surgeon whom she had attended to have her right thumb amputated on account of a most severe form of the affection. The history given of her infancy was suspicious, but by no means positive. The result of treatment, however, fully bore out the diagnosis, for although no benefit accrued during the first ten days of the mercurial, and indeed the ulceration threatened to become phagadenic, yet no sooner was the constitution brought under the influence of the remedy than the most rapid healing resulted. Dusting of chlorate of potash into the sore was the only local application which had been used, and to it perhaps some part of the credit should be given. The thumb end still remains clubbed and unsightly, but a new nail has partially formed, and in time the thickening will no doubt subside. The second case was a much more valuable one as regards positive evidence as to its pathology. A child, three years old, was brought to the hospital, presenting an onychia maligna of well-marked features, which had followed a slight trap of the thumb in the door. Her mother stated that she had been Mr. Hutchinson's patient in infancy, and on referring back to the notes it was found that when a few weeks old she had been treated for congenital syphilis. This recorded fact was the more valuable because, excepting the onychia, there was nothing in the child's present appearance which would have suggested a suspicion of hereditary taint. It was evident that the injury received had merely been the means of exciting and localising a latent predisposition. Mercurials were prescribed, and the thumb soon got well. It follows as a consequence that if this pathology of the disease be the correct one, amputation is never necessary. It has been long acknowledged by many Surgeons that onychia maligna in the adult is an occasional though very rare symptom of acquired constitutional syphilis. Mr. Hutchinson holds confidently that this affection, when met with as it usually is in cachectic children, is in a vast majority of instances a manifestation of hereditary syphilitic taint, and curable by mercury.

### DEATH AFTER EXCISION OF THE KNEE-JOINT.

We mentioned a month ago a case in which the knee-joint had been excised by Mr. P. Price in the "Great Northern" Hospital, on account of rectangular anchylosis. It will be remembered that the patient, a lad of 19, was in good health, and that all disease in the joint had long subsided. It was therefore an *operation de complaisance*, and we regret to have to add that it has been followed by a fatal result. The poor fellow sank under double pleuro-pneumonia on the thirtieth day after the operation. The chest symptoms set in on the

seventh day, and excepting some sloughing of the skin the parts concerned in the excision had been doing favourably. The bones were in good position throughout, but a portion of the femur was bared of periosteum. The alternatives of the procedure which was adopted, would have been either to have amputated below the knee, or to have allowed the lad to remain as he was, with a stump fitted to the knee, and the leg projecting behind.

#### RAPID DEATH FROM LACERATION OF THE KIDNEY.

The very rapidly fatal effects of a laceration of the kidney from contusion were well exemplified by a case which occurred a short time ago under the care of Mr. Paget, in St. Bartholomew's. A little girl, previously in excellent health, was admitted, having been run over by a cart, the wheel of which was stated to have passed over her back. There were no external marks of bruising. She was pallid, pulseless, and in deep collapse. Death followed ten minutes after admission, and twenty from the time of the accident. At the autopsy the chief injury found was an extensive laceration of the right kidney. There was also a small quantity of blood in the right pleural sac, although no fracture of the ribs or laceration of the lung could be detected. The intestines were uninjured, and there was no ecchymosis about the lumbar region. The profound collapse in this case and the rapid death are features which present a very marked difference from what usually follows rupture of the bladder. After the latter accident, so contrary from what might have been expected, the evidences of shock are often very slight, and the supervention of serious symptoms long delayed. In the one case, however, it must be remembered that death ensues directly from the shock consequent on injury to a large and highly organized viscus, whilst on the other it is merely secondary, and dependent upon the extravasation of the contents of a hollow organ, which is of itself fairly tolerant of violence.

#### ANTIMONY IN DELIRIUM TREMENS.

Mr. Paget has recently employed antimony in combination with opium in the treatment of some cases of the more ethenic form of delirium tremens under his care in St. Bartholomew's, and has expressed himself well satisfied with the results. The practice is, of course, nowise novel, but it is an important one to be borne in mind. The experience of many bears out the fact that in cases in which opium alone does not succeed in allaying nervous excitement the addition of salines or of ipecacuanha often will. Thus a much smaller dose of the narcotic will be required for a given effect. We need hardly add that the combination of antimony with opium was a very favourite one with Dr. Graves.

#### PATELLA MOVABLE AFTER EXCISION OF THE KNEE-JOINT.

Our attention was drawn the other day to the case of a man upon whom Mr. Fergusson had performed excision of the knee-joint in King's College Hospital, fourteen months before. He could walk exceedingly well, with only a limp, which was so slight as to be scarcely noticeable. The femur and tibia were firmly ankylosed together and quite straight, but the patella had nearly its natural range of motion. Mobility of this bone would, no doubt, be an important addition to the efficiency of the quadriceps extensor, and seeing that the joint had been freely excised in the usual way, the ligaments patellæ being cut across, that it should have been secured was certainly more than might have been expected.

#### ERRATUM.

We are anxious to correct prominently an important mistake which occurred in one of our Hospital Notes last week. The salt employed by Mr. Lloyd at St. Bartholomew's as an injection, application to warts, etc., is not the *bichromate*, but the *permanganate* of potash.

ELECTIONS AT THE ACADEMIE DES SCIENCES. — A vacancy having arisen in the section of Mineralogy and Geology by the death of M. Dufrenoy, the section placed the candidates thus on the list: 1. M. Daubrée; 2. M. Charles Sainte-Claire Deville; and other candidates in a third line. The Academy, however, declined to accept this disposition, and elected M. Sainte-Claire Deville by thirty-five votes from among fifty-eight. M. Despretz has been elected president, and M. de Sénarmont vice-president, for the year 1868.

#### TERMS OF SUBSCRIPTION.

## Medical Times & Gazette.

SATURDAY, JANUARY 16.

#### THE ANATOMY ACT AND ITS ADMINISTRATION.

SUBJECTS for dissection are scarce and dear in London; they are plentiful and cheap in Dublin and Edinburgh. These are facts. The natural inference to which they lead is that the Anatomy Act is well worked by efficient Inspectors in Dublin and Edinburgh, and that it is badly worked by the respectable Inspector in London. We shall not examine just now how far this inference is borne out by other facts; but as very general dissatisfaction prevails in all the schools and among the teachers of Anatomy and Surgery in London, and as a great public scandal has been excited by the recent exposures at the Newington Workhouse, it becomes necessary to point out certain clauses in the Act which may be amended, and certain abuses which must be remedied by more efficient working of the present or the amended Act.

Some five-and-twenty or thirty years ago there was nearly as much difficulty in supplying the dissecting rooms as there is now. The "resurrectionists" or "body-snatchers" could not meet the demand. Subjects commanded a high price, and the demand was met by Bishop, Burke, and Hare, who supplied the dissecting-rooms of London and Edinburgh with the bodies of poor creatures they entrapped and murdered. The crimes of these villains led to the passing of Mr. Warburton's Act in 1832, "An Act for regulating Schools of Anatomy." This is the Act which is now found wanting, and which the London teachers are either obliged to infringe, or to connive at infringements, before they can obtain a sufficient supply of subjects for dissection. A specimen of the infringements, far from uncommon as we believe, has lately been exposed at Newington.

The master of the workhouse of this parish, Mr. Feist, it appears—and here we quote the *Morning Post*—"has been in the habit of unlawfully removing the dead bodies of paupers, to dispose of them for profit; and that Mr. Mark Shaddock, the accountant of Guy's Hospital, had paid to him, over and above the usual price, a gratuity of about ten shillings for each body. In the cross-examination of Mr. Shaddock, it was elicited that similar gratuities had, since 1849, been paid by the authorities of the Medical School of Guy's Hospital to successive masters of the Newington Workhouse. In 1856 these gratuities amounted to £19 10s., and in 1857 to £26. Mr. Shaddock ought to have known that the law declares it to be a misdemeanour for the master of a workhouse to receive, on any pretence whatever, fees from an Hospital official. With that knowledge, he ought not to have allowed himself to become, on behalf of his employers, the tempter of another to take unlawful possession of the bodies of paupers. It appears that Mr. Feist, in several instances, led friends and relatives of deceased paupers to believe that they were following bodies to the grave which he knew had been removed

to Guy's Hospital, to be there used as subjects for anatomical teaching." . . . "It further appeared, from the evidence of the workhouse undertaker, that dissected bodies, or parts of dissected bodies, returned from the Hospitals for interment, were frequently substituted for undissected bodies, the latter being thus illegally and deceitfully obtained for anatomical purposes. In other words, mourners, when following what they supposed to be the body of a deceased friend or relative, were following the dissected remains of some other person."

Of course such things as these excite just feelings of alarm and distrust in the public mind. It is obvious that under the present working of the Act, its provisions may be easily and constantly evaded by workhouse underlings and interested undertakers' men. It is perfectly well known that if a body is particularly wanted at any school, and it cannot be obtained in the regular way, it can be obtained surreptitiously. This cannot continue, consistently with the public safety. The secondary effect of bribing the masters of workhouses and low-class undertakers will be to raise up some emulator of Bishop, Burke, and Hare. Let us take warning in time, then,—the Act must be amended, and its provisions must be enforced by active and intelligent inspectors.

The Act contains twenty-one clauses. The first enacts that the Secretary of State may grant licences to Medical men to "carry on the practice of anatomy." In the second and third the said Secretary is to appoint Inspectors of Schools of Anatomy, and to appoint the districts each Inspector is to superintend. In the fourth and fifth some of the duties of the Inspector are defined. All this is unobjectionable. But the sixth requires immediate amendment, inasmuch as the annual salaries of the gentlemen who are appointed to perform the important duties of Inspectors must not exceed *One Hundred Pounds!* It is perfectly absurd to suppose that any one can do the work that should be done by an Inspector well for such a paltry remuneration. The salary should certainly not be less than five hundred a-year, and it ought to be six or eight. What lawyer would work for the country on such terms?

The seventh clause is that which requires the chief alteration and amendment. Here it is:—

"And be it enacted, that it shall be lawful for any executor or other party having lawful possession of the body of any deceased person, and not being an undertaker or other party entrusted with the body for the purpose only of interment, to permit the body of such deceased person to undergo anatomical examination, unless to the knowledge of such executor, or other party, such person shall have expressed his desire, either in writing at any time during his life, or verbally in the presence of two or more witnesses during the illness whereof he died, that his body after death might not undergo such examination, or unless the surviving husband or wife, or any known relative of the deceased person, shall require the body to be interred without such examination."

This clause is open to numerous objections. It does nothing to provide a supply of subjects for the schools. It legalizes a demoralizing traffic in dead bodies between relatives and teachers; it puts a double power in the hands of Poor-law guardians and workhouse authorities. On the one hand they can send bodies to the schools to save the expense of burial, or defraud surviving relatives under the "gratuity" system, in which Mr. Shaddock seems to be such an adept. On the other, they can throw insuperable obstacles in the way of anatomists, by inducing sick people to express some objection to dissection. This clause must be altered altogether. The schools should be supplied by a clause making it lawful for the Inspector of Anatomy to demand the bodies of all persons who die unclaimed in workhouses, hospitals, and public institutions. Such a clause could not offend popular feeling, and it would put an effectual check upon

present abuses, and avert the possible results of present temptations.

The remaining clauses of the Act might stand unaltered; but we must call attention to a very great abuse which has crept into the working of the 13th clause. This merely makes provision for interment "in some public burial ground," and the mode of removal of bodies "in a decent coffin or shell." But in practice a sort of monopoly appears to be granted to certain undertakers, and it is their exorbitant charges which make the main difference between the price of subjects in London, and in the chief towns of Scotland and Ireland. Last year a meeting of many of the London teachers was held, when it appeared that a saving of twenty-two shillings upon every subject might be effected by employing the London Necropolis Company. The Company offered to transport the bodies from the Workhouses to the Schools, and from the Schools to the Woking Cemetery, for twenty-two shillings less than the undertaker's charge. Not only was the Company refused the necessary permission, but this year the undertaker's charge has been raised ten shillings, so that Medical Students must now pay £3 2s. instead of the £2 12s. they paid last year for the burial fees; although that £2 12s. was and is £1 2s. too much for every subject taken from the pockets of teachers and students. This is a gross abuse of the 13th clause of the Act, which we trust will be brought before Sir George Grey immediately.

#### ARSENIC IN PAPER-HANGINGS.

IN our Journal for May 23, 1857, we published a letter from Dr. Hinds, of Birmingham, describing the danger likely to arise from the extensive employment in this country of a green arsenical compound for the colouring of paper-hangings. During the last week the subject has been noticed in the *Times*, and a letter inserted in that journal from a Mr. Fletcher, who announces to the public that there is no danger in the use of arsenic under such circumstances. The writer is, however, an arsenical colour-manufacturer, and it would be, of course, more difficult to convince him of the existence of danger from such a cause, than others who do not profit by the spreading of arsenic on the walls of our sitting and bed rooms.

In Dr. Hinds' case the symptoms produced were severe prostration of strength, headaches, a low febrile state of system, an inflammatory state of the conjunctiva, thirst, loss of appetite, and heat and dryness of the throat, with tightness across the forehead. These are the symptoms of chronic poisoning by arsenic. There was no source of arsenic but the bright green wall-paper of the room in which the patient passed so many hours of his time. Several other cases of a similar kind have occurred, and there may be hundreds of cases in which some or all of these symptoms exist, but the cause is unsuspected, and the patients are treated for dyspepsia, gastritis, etc.

In the kingdom of Prussia, in which free trade in poisons does not exist, the following regulation is in force:—

"Green copper colours containing arsenic are not allowed to be sold as water or oil colours for painting in-door work, or for printing paper-hangings. If found on the premises of dealers in the latter articles they are confiscated, and the owner punished with fine or imprisonment."

We presume that such a regulation as this would not have been issued without some good reasons to warrant it; and that had the Prussian government referred the question to arsenical colour-makers no such regulation would have been made. Those who profit, however, by the slow poisoning of the public in adding green pigments to pickles, or spreading them in a loose form on paper-hangings, either altogether deny that injury can arise from this branch of industry, or they assign it to other causes.

# SUICIDAL MELANCHOLY.

From a Photograph by Dr Diamond

*Drawn on Stone by W. Bagg*

*Printed by Hullmandel & Co.*

The mode in which the poison on paper-hangings finds its way into the body demands further inquiry. It is probably in the form of an impalpable dust, diffused through the atmosphere of the room; and is therefore more likely to issue from flock and rough green paper than from those which are glazed or coated with varnish or oil. It would be, perhaps, at any time difficult to detect arsenic or arsenite of copper in the air of a room thus papered; but let our Medical readers consider that an attack of painter's colic has frequently occurred from a slight exposure to the air of a recently painted room, and no one has pretended to detect the vapour of carbonate of lead in the air which must have transmitted the poison. The insidious mode in which modern discovery has proved lead-poisoning to take place, should teach us that we have much to learn regarding the operation of other poisons. Some persons are more susceptible of the effects of lead than others, and the same may be true of arsenic.

By those who know the nature of arsenical pigments, of the noxious effects produced some years since among workmen and on the public by the use of arsenic in the manufacture of candles—the statement of the *Times* correspondent, Mr. Fletcher (the arsenic-pigment maker), will be duly appreciated. He there ventures to tell the public through the *Times*, that “workmen who have been daily employed for many years in manufacturing large quantities of these (arsenical) colours, under the necessity of constantly handling them, are in the regular enjoyment of perfect health.” Probably, as in the alleged arsenic-eaters of Styria, he might go a step further, and be able to inform us that his men are in blooming health, remarkable for their florid complexions, strength of wind, and good appetites! According to this writer, there is nothing like “arsenic” where we wish to have a good and durable green colour; and because his workmen can (as he says) breathe and handle arsenical compounds for many years with impunity, he recommends the public to disregard the suggestion that any danger can possibly arise from this profitable branch of manufacture. Foreign governments are labouring under a mistake, and English Medical men are under a delusion!

We may add, that the paper is not merely used for hangings, but for wrapping articles of food, tobacco, snuff, etc. At a railway station in the north of England we purchased, during the last summer, a packet of soft cakes. They were in what Mr. Fletcher calls a bright, “cheerful” green paper-wrapper. On examining the pigment, which was coarsely laid on the thin paper-wrapper, we found it to consist of arsenic and copper? Such packets should have the Prussian symbol of poison, namely, a death's head and cross-bones stamped conspicuously in black on the outside, with the motto, “Memento mori.”

Since writing the above, we have seen in the *Times* a letter from Dr. Halley, confirming in every particular the views of Dr. Hinds, respecting the noxious effects of arsenical green papers on health. Dr. Halley states that he has detected and separated arsenic by means of an aspirator. The important portions of his letter will be found in another column.

#### THE WEEK.

WE are able to state by authority that the last authentic reports received by the mail from India stated that the “sick and wounded are going on most prosperously, and all that is necessary for their care and comfort is possessed in abundance.” The sick and wounded from Delhi have been removed to Umballah. It has become the fashion to praise the East India Company for the excellence of their Medical arrangements. Without disparaging these arrangements in any way, we can state that the Army Medical Department in

India does not fear a comparison with that of the Company. The supply of Medical officers is abundant, as there are no less than 397 now in India for the Queen's troops only.

Mr. Griffin, having solicited and received suggestions from numerous quarters upon the subject of the Draft of his proposed Bill of Poor-law Medical Reform, has now issued an amended Draft of that measure. A copy of the amended Bill has been sent, we understand, to all the Medical Poor-law officers, as far as their addresses could be ascertained; but if any of those gentlemen have not received one, Mr. Griffin will be happy to forward one on application, as the omission has been only accidental. Among the alterations made in the present Bill, we observe that Mr. Griffin has abandoned his original proposition of remunerating the Poor-law Medical officers by paying them a certain sum for each case, and has substituted a fixed salary, founded upon the number of cases attended during a given series of years. Mr. Griffin again invites comments and suggestions upon his plan, and requests that any communications of that nature may be immediately sent to him, as he intends forthwith to print the proposed Bill in the form of a pamphlet, together with the Rules, Orders, and Regulations of the Poor-law Board, bearing upon the whole subject. This detail will be accompanied by a copy of the decisions and opinions on the cases submitted to the Board during the last seventeen years, as recorded in the official circulars. From these materials arguments will be drawn to prove the necessity of the different sections of Mr. Griffin's Bill; and each member of the Legislature will receive a copy of the documents thus brought together for their consideration. The subscribers to the Poor-law Medical Reform Association will also receive a copy, and one would be sent to every Poor-law Medical officer, if the funds in hand would permit of such a course, which we regret to find is not the case. Mr. Griffin therefore calls upon all those who have not yet subscribed towards the funds of the Association to do so as soon as possible, in order that the efforts now being so strenuously made may not fail from want of support. We are glad to learn, however, that nearly two hundred Union officers have forwarded their subscriptions during the past month, many of whom are new members; but it is necessary that many more new adherents should flock to Mr. Griffin's standard, to compensate for the deficiencies which have necessarily occurred, from the circumstance that since the agitation many Union officers have thrown up their situations in disgust. We must earnestly impress upon the Poor-law Surgeons the necessity of cordial co-operation in endeavouring to obtain their rights.

Lisbon has been declared officially as free from yellow fever since the 24th ult., nearly 5000 deaths having taken place among the 13,500 persons attacked. The fact that this disease may be imported into Europe from the Brazils, the coast of America, the West Indies, and the coast of Africa is now generally acknowledged. In France precautions have been adopted accordingly, and all the lazarettoes of the French ports are being prepared for the reception of invalids. It is high time that proper provision be made in this country for the segregation of cases of contagious disease arriving here from abroad. It can be done most easily, without running into any of the absurdities which followed this abuse of the quarantine regulations.

The narrative of the siege of Lucknow has arrived, and amid the unparalleled hardships of the defence our Medical brethren are recorded as distinguished in the discharge of their duty, so much so that they have received special men-

tion in the despatch of the Governor-General. The following extract from this despatch will be read with just pride, and we trust that as these members of our Profession have shared in the danger of their comrades they will also receive their due share in the rewards which all have so well deserved:—

"The Medical officers of the garrison are well entitled to the cordial thanks of the Government of India. The attention, skill, and energy evinced by Superintending-Surgeon Scott; Assistant-Surgeon Boyd, Her Majesty's 32nd Foot; Assistant-Surgeon Bird, of the Artillery; Surgeon Campbell, 7th Light Cavalry; Surgeon Brydon, 71st Native Infantry; Surgeon Ogilvie, Sanitary Commissioner; Assistant-Surgeon Fayrer; Assistant-Surgeon Partridge, 2nd Oude Irregulars; Assistant-Surgeons Greenhow and Darby, and of Mr. Apothecary Thompson, are spoken of in high terms by Brigadier Inglis. To Dr. Brydon especially the Governor-General in Council would address his hearty congratulations. This officer, after passing through the Cabul campaign of 1841-42, was included in the illustrious garrison who maintained their position in Jellahbad. He may now, as one of the heroes of Lucknow, claim to have witnessed and taken part in an achievement even more conspicuous as an example of the invincible energy and enduring courage of British soldiers."

In the reported subsequent operations against the Gwalior Contingent, Brigadier-General Grant has made favourable mention of Surgeon J. C. Brown, M.D., Bengal Horse Artillery, whose great exertions have been deserving of all praise. He has since become Superintendent-Surgeon of the Force.

Mr. Gant has done good service to the public by exposing some of the evils of the modern system of fattening cattle. We entered at some length into this subject last year in a series of articles on the relations of food and disease, and Mr. Gant has inspected the prize animals at the last exhibition of the Smithfield Cattle Club, has followed them to their destinations, and inspected them after death. He found exactly what any one would expect to find who had thought upon the physiological aspect of the question—fatty degeneration of the muscular tissue, and excessive deposit of fat in those situations where it is normally present. He also found numerous filarise in the lungs, tubercles in various stages, congested livers, and all the signs of general venous engorgement. It is quite clear that the nutritive value of the flesh of such animals is most materially diminished by the conversion into fat. A certain admixture of fat and muscle is desirable, but the conversion of muscle into fat is a change which seriously impairs the quality of meat. So far from these overfed animals being deemed worthy of a prize, the breeders should be condemned to a penalty. The panting breathlessness from the congested lungs and weakened heart, the dull, stupid expression from the congested brain, the inability to move, are positively disgraceful to agriculturists, and should certainly attract the attention of the Society for the Prevention of Cruelty to Animals.

Another case of midwifery malpraxis has been brought to light. A coroner's jury at Maidstone has investigated the cause of death of a woman treated by two practitioners, one of whom has no legal qualification, and the other is an aged man, who was in practice before 1815. We have not received accounts of the termination of the inquiry, but enough has transpired to show that the forceps had been applied upon the gravid uterus, and that the uterus had been rent either by the forceps or crotchet. We shall receive, hereafter, full details of the Medical evidence.

## REVIEWS.

*The Use of the Microscope in Clinical Medicine.* Illustrated. By LIONEL S. BEALE, M.B. F.R.S. Physician to King's College Hospital, and Professor of Physiology and of General and Morbid Anatomy in King's College, London. No. I. Urinary Deposits. London: 1857.

*Archives of Medicine: a Record of Practical Observations and Anatomical and Chemical Researches connected with the investigation and treatment of Disease.* Edited by LIONEL S. BEALE, M.B. F.R.S. No. I. London: 1857.

THE first number of Dr. Beale's series on the use of the microscope in Clinical medicine, is devoted to the representation and description of urinary deposits. There are fourteen illustrations, accompanied by short explanatory notes, together with a short description of the general characters of each deposit, and of the tests employed for its detection. The first three plates are filled with the microscopical appearances presented by extraneous matters sometimes accidentally introduced into urine, and the discovery of which by the incautious observer has occasioned serious mistakes. These bodies consist of hair, flax-fibres, tea-leaves, starch of various kinds, bread-crumbs, air-bubbles, oil-globules, portions of feather, fibres of cotton, and other similar matters. The thorough appreciation of the characters presented by such objects will save the young microscopist from falling into many errors. Four plates are devoted to the forms presented by lithic acid, the various crystalline characters of which are faithfully and amply delineated. The other illustrations comprise the appearances presented by the lithates, the ammoniaco-magnesian phosphate, cystine, the oxalate and oxalurate of lime, spermatozoa, and the casts of the uriniferous tubes. The following remarks upon the presence of spermatozoa in the urine are very just, and may afford consolation to some persons who have been duped by the "Manly Vigour" quacks:—

"Spermatozoa are not unusually found in the urine of men in perfect health; and it is only when very frequently met with, and in cases where their discharge is associated with serious impairment of the health, that their presence can be regarded as affording any indication for the active interference of the Physician."

In reference to the same subject, however, a curious instance is recorded in Dr. Beale's "Archives of Medicine," where spermatozoa were distinctly found in the vaginal mucus of a young girl, brought last summer into King's College Hospital, and on whom a rape was said to have been committed about three hours before.

The illustrations of the use of the microscope will be found of great service, not only to the student but to the practitioner, and the very moderate price at which the numbers are published will no doubt insure a large circulation. "The representations have been accurately copied from the objects in the microscope, with the aid of the neutral-tint glass reflector. The image has been traced on properly prepared paper, from which it has been directly transferred to the lithographic stone. The drawings," continues Dr. Beale, "have all been made under my direct superintendence, and in some instances by myself." Thus all the necessary means are taken to insure accuracy.

In his other publication, the "Archives of Medicine," it is the intention of Dr. Beale to present the results of experiments and observation made in his own laboratory and microscope room; but he also proposes to accept the co-operation of others who are labouring in the same researches as himself. His first number is a promising one, and contains papers by himself as editor, by Dr. Todd, and Dr. Moritz von Bose. The subjects proposed for papers in future numbers are practical clinical observations, original researches in physiology and pathology, results of chemical and microscopical examinations of healthy and morbid organs and secretions, descriptions of different processes employed for demonstrating various structures, and condensed reports of the researches of observers published elsewhere.

*Alcohol: its Place and Power.* By JAMES MILLER, F.R.S.E. F.R.C.S.E. Professor of Surgery in the University of Edinburgh. Pp. 161. Glasgow: 1858.

THIS little work, written by Professor Miller, was presented as a gift to the Scottish Temperance League, at the request of which body he had undertaken the task; and it is published

in a cheap form, so as to bring it within the reach of all classes. To the Medical reader it contains nothing very novel or striking; but the simple and homely style in which it is composed is very well adapted to warn the multitude of the evils brought upon mankind by the abuse of alcoholic stimulants. Professor Miller very ably points out the use of these agents in the treatment of disease, some forms of which imperatively demand their employment; while at the same time he argues that their indiscriminate consumption is not only productive of direct mischief, but it also renders the constitution less amenable to their beneficial operation when the necessity arises for their administration. We are glad to find that Dr. Miller appreciates the value of alcoholic fluids in certain states of disease, and in some conditions of the system, because some *quasi* Medical writers, in their zeal in the cause of Temperance and Tee-totalism, have gone so far as to denounce their use altogether, and to regard them only in the light of unmitigated poisons. Professor Miller's book will, no doubt, be productive of much benefit to the classes to whom it is addressed.

*Die Adergeflechte des menschlichen Gehirnes.* Von Professor HUBERT LUSCHKA. Pp. 174. Berlin: 1867.

*The Choroid Plexuses of the Human Brain.* By Professor LUSCHKA.

UP to the present time anatomists have not agreed on several points in the anatomy of the centres of the nervous system, especially on the existence or not in adult age of a canal in the interior of the cord, easily to be observed in fetal life; or whether there be a communication of the subarachnoid space with the ventricles of the brain, and the corresponding space in the cord, or not, etc. Professor Luschka, of Tübingen, well known to anatomists by his treatise on the anatomy of the generative organs, has taken up some of these doubtful points, and brought them, as it seems, to a satisfactory conclusion, chiefly by his researches on the bodies of three healthy criminals who were executed at Tübingen.

It follows from the researches of Professor Luschka, that the existence of a canal in the interior of the cord in adult age is in some cases beyond doubt. Often, however, this canal seems to be completely obstructed and filled by cellular tissue, epithelium, and amyloid corpuscles.

The communication of the subarachnoid spaces with the ventricles of the brain, and with the subarachnoid space of the cord, has recently been denied by Professors Virchow and Kölliker at Würzburg. Professor Luschka, however, proves the existence of this communication by anatomic preparations, by experiments on dead bodies, and by appeal to well-established surgical facts, so that we can no longer doubt that there is really a floating to and fro of the cerebro-spinal fluid from the brain to the cord, and *vice versa*.

As the arachnoid membrane spans like a bridge over the convolutions and furrows of the upper surface of the brain, the pia mater being in the depth of these furrows, there must be spaces filled by fluid, and these are in open communication with each other. Similar spaces or sinuses exist on the base of the brain, out of which cerebro-spinal fluid flows in cases of fractures of the skull. The largest subarachnoid sinus on the base of the brain communicates with the fourth ventricle, and thereby with all the ventricles of the brain. From this space may be drawn a very large quantity of cerebro-spinal fluid, as well in the dead human body as in the living animal, the whole mass of which has certainly not been contained in this single space, but has come from the other spaces with which it is in open communication.

It has been proved by surgical observations and post-mortem examinations made by Sir Charles Bell and Guthrie in this country, by Laugier and Chassaignac in France, and by Diefenbach and Wutzer in Germany, that in cases of fracture of the sphenoid bone some cerebro-spinal fluid comes out of the nostrils; this proceeds from a subarachnoid sinus lying between the crura cerebri, the margin of the pons Varolii, and the commissure of the optic nerves, corresponding to the sphenoid bone. It has equally been proved that in cases of fracture of the petrous bone, cerebro-spinal fluid comes out of the ear; then the walls have been torn of the subarachnoid sinus on the anterior margin of the pons Varolii, just on the conjunction between the petrous part of the temporal bone and the margin of the body of the occipital bone.

The experiments made by Professor Luschka for proving the

existence of a communication of the different subarachnoid spaces with each other, and with the ventricles of the brain, are interesting and conclusive. A fresh corpse was suspended by the feet for four hours, so that the head hung quite free. Then the skull-cap and the dura mater were taken off. The arachnoid membrane was found very much enlarged by fluid collected under it, and in some places was prominent like a bubble. It was then cut open, and one and a half ounce of cerebro-spinal fluid came out. Another corpse having been suspended by the head during five hours, the skull-cap was removed, and the dura-mater cut open. The subarachnoid spaces now appeared quite empty, and the arachnoid membrane sunk into the furrows of the brain. The head of another body was cut off at the fifth cervical vertebra, a tube introduced under the arachnoid membrane, and some ink mixed with water driven in by very gentle pressure of a syringe. Some time after the head was held in an inverted position, in order to bring the fluid into the subarachnoid spaces and ventricles of the brain more by their specific weight than by the pressure of the syringe. The skull-cap and the dura mater were then removed, and the spinal fluid was not only seen on most of the parts of the hemispheres of the brain, and in the sinuses at the base of the brain, but likewise in the fourth ventricle, from which it had even come through the aqueductus Sylvii into the third ventricle.

For imitating artificially such fractures of the skull as are connected with loss of cerebro-spinal fluid, Professor Luschka perforated, by means of a trephine introduced into the nose, the body of the sphenoid bone, the dura mater and the arachnoid membrane. Instantly a clear fluid came out, and a much larger quantity could be taken off by a syringe. Further, he introduced the trephine into the external opening of the ear, and perforated the membrana tympani and the labyrinth in the direction of the internal opening of the ear, with the same result.

Finally, air was blown into the subarachnoid spaces of the cords of three men who had just been decapitated, and in whom all the cerebro-spinal fluid had come out through the widely opened subarachnoid space of the cord. The air penetrated from this space into the subarachnoid spaces, as well as into all the ventricles of the brain. This fact alone would leave no doubt about the communication between all the subarachnoid spaces and with the ventricles.

This brief and imperfect outline may be sufficient to prove the importance of the work by Professor Luschka, which contains besides a great amount of valuable information on many interesting points in the microscopic anatomy of the brain. It is illustrated by four well-executed engravings.

## PROGRESS OF MEDICAL SCIENCE.

### Selections from Foreign Journals.

#### ON THE EMPLOYMENT OF COLLODION IN ORCHITIS.

By Dr. LOSSETTI.

HAVING treated 64 cases of gonorrhoeal orchitis in the Maggiore Hospital, Milan, solely by means of collodion, Dr. Lossetti comes to the following conclusions:—1. Orchitis, epididymitis, or inflammation of the spermatic cord, even when intense, arising from blennorrhagia, yields much more readily to the application of collodion than to the ordinary antiphlogistic treatment, actively employed. 2. The most efficacious means of obtaining certain and rapid recovery is the application of the collodion (the author prefers to pure collodion a mixture of one part of castor oil and twenty-four parts of collodion) twice a-day until the cure is completed, applying it oftener, however, in cases of extreme gravity. 3. Under the use of the collodion, the indurations and enlargements which remain after the relief of the inflammatory action will be dispersed without the aid of any other means. 4. By means of its application, the erysipelas of the scrotum that sometimes complicates the orchitis becomes resolved, and the cellular infiltration that almost always accompanies or succeeds it disappears. 5. The treatment required besides only consists in the observance of a low diet, rest, and cooling drinks. 6. This mode of treatment is more economical than the antiphlogistic mode, by reason of the shorter time it requires (accord-

ing to the author's cases, eight days as compared to fourteen by the ordinary treatment), and the saving of expensive remedies, as leeches, etc. 7. The treatment is also to be preferred, since the digestive organs are not disturbed by active purgation, and the general powers are not enfeebled by this and the abstraction of blood. 8. The sensation of burning produced by the application of the collodion never amounts to the extent of acting as a contra-indication. It becomes violent, and even insupportable, only when some minute lesions of continuity of the skin of the scrotum are present; and these only require to be protected by cerate or court plaister, to enable the patient to bear the application.—*Omodei Annali Universali*, vol. clix. pp. 315—341.

#### ON THE FORMATION OF ARTIFICIAL PUPIL BY GALVANO-CAUTERIZATION.

By M. TAVIGNOT.

M. Tavignot, after enumerating various circumstances which may render the results of the ordinary operation for artificial pupil unsatisfactory, states that he has been for some time considering the applicability of the galvanic cautery for this operation, and has succeeded in employing it. Its chief advantages are, that the new pupil may by it be established instantly, and without hæmorrhage, and that its dimensions and shape can be exactly determined. Being a more simple manœuvre than the tearing through the iris, it is less likely to be followed by inflammatory consequences. Moreover, the aperture can as easily be made in the cases in which false membranes line the posterior surface of the iris, or obstruct its central portion. Thus far he only deems this procedure applicable to subjects who have already undergone the operation for cataract; as in the case of the lens being present its opacity would be induced during the application of the caustic. M. Tavignot prefers Bunsen's pile; and having made an incision at the external circumference of the cornea, he passes in the caustic-rod, directing its platinum ring to the point he wishes to influence, taking care not to cauterize the posterior surface of the cornea, nor the edges of the wound.—*Moniteur des Hôpitaux*, 1857, No. 119.

#### ON RESECTION IN COMPOUND DISLOCATIONS.

By Professor HAMILTON.

In this paper Professor Hamilton, of Buffalo, relates an interesting case of compound dislocation of the tibia inwards, together with fracture of the fibula, and in which a very useful limb followed resection of the lower end of the tibia. He enters into the question of treatment at some length. As compared with simple dislocation, the accident is of very rare occurrence; for of 94 instances of dislocation reported by Norris, only two were compound, and both these were dislocations of the thumb. Among 166 dislocations, recorded formerly by Dr. Hamilton himself, there were only 8 examples of compound. Of these 4 were dislocations of the tibia inwards at the ankle-joint, 1 was a partial (pathological) dislocation forwards of the same joint, 1 was a luxation of the astragalus, 1 a luxation of the humerus into the axilla, and 1 a forward luxation of the radius and ulna at the wrist-joint. Compound dislocation is a much more dangerous accident than compound fracture; and Dr. Hamilton does not think A. Cooper succeeded in assigning sufficient cause for the difference. He believes, himself, that it is chiefly to be found in the fact that dislocations are usually reduced and maintained in place by apparatus, while compound fractures are not in general reduced, and if they are, cannot be maintained in position. It is to the stretching and strain of the muscles, tendons, and other soft tissues, during and subsequent to reduction, that the mischief is chiefly due.

Dr. Hamilton passes in review the various other means of treating the accident, viz. leaving the part unreduced, amputation, tenotomy, and resection, and gives the entire preference to this last, as being that which most conduces to the security of life and the preservation of a useful limb. As to the first points, "if we consider the life of the patient only, the arguments and the testimony seem to favour resection in a great majority of cases of compound dislocation occurring in large joints, and in a considerable number of cases of similar accidents in the smaller joints. It is certainly more safe than reduction without resection or non-reduction, and it is probably quite as safe as tenotomy or amputation." As to the amount of maiming or mutilation, the question lies between reduction without and reduction with resection.

1. In either case the inflammation consequent upon the injury may be violent, and the recovery tedious; but the amount of resulting maiming must much depend upon the duration and intensity of the inflammation, and upon this point testimony is in favour of resection. "It will be observed that not only is the danger of maiming rendered more considerable by reduction without resection, because the inflammation is so much more likely to extend to the tendons and muscles, causing them to adhere to each other, and to become subsequently atrophied, a condition from which they often never completely recover, but also because the ligaments and capsules of the joints, with the synovial surfaces, are in consequence encroached upon, and the freedom of motion is ever afterwards greatly restricted, if not completely lost. This marked impairment of the functions of the joint does not always happen, but it cannot be denied that it does generally. How is it, on the other hand, with these joints after resection? I have thus far heard of no cases in which complete ankylosis resulted; but in all considerable freedom of motion has returned, and in some the restoration in this respect has been nearly or quite as complete as before the accident." 2. The limb can be retained in place far more easily after resection than when this is not performed. 3. The amount of shortening after resection need not exceed three-quarters of an inch, and is often not more than half an inch—an amount of shortening that does not necessarily produce a halt, and the existence of which may not be known to the patient.—*American Journal of Medical Science*, Oct. pp. 324—337.

#### ON THE TREATMENT OF PROLAPSUS OF THE IRIS.

By M. TAVIGNOT.

In a clinical point of view it is of importance to consider the various circumstances under which this may occur, circumstances that may render it either an unfortunate, or, so to say, a fortunate accident. It is not so much the aspect of the prolapsed iris we have to take into account as the exact nature of the solution of continuity of the cornea itself.

1. When the division of the cornea is made without loss of substance, as is usually the case in a wound by a cutting instrument, the cornea is placed in the best possible condition for the process of reparation. This, if no obstacle presents itself, takes place by the aid of a kind of exudation of corneal juice, the resulting cicatrix being consequently transparent, while it would have been more or less opaque if effected by plastic lymph. It is plain that the presence of the iris would only act as an impediment to this mode of union, by keeping the lips of the wound asunder, and by itself furnishing reparative material, and leading to an opaque cicatrix. We should therefore endeavour to procure the permanent retraction of the prolapsed portion into the posterior chamber; but this must be sought to be accomplished differently, accordingly as the prolapse is of recent or old date. (1.) When it is quite recent (twenty-four hours), we should try to reduce it by the end of a blunt probe, slightly enlarging the wound by incision, if necessary, to effect this. At the same time we must obtain the co-operation of the iris itself in facilitating the reduction, and rendering it durable. In doing this we must bear in mind two important points: first, that it is always the pupillary edge of the iris that first tends to pass into the opening; and, secondly, that it is necessary to provoke sometimes the contraction, and sometimes the dilatation of the iris, accordingly as the aperture is situated towards the periphery or centre of the cornea—in order, in both cases, to secure traction on the adhesions by which the iris is engaged within the cornea. If when the wound is *peripheric* we dilate the pupil by means of belladonna, we paralyze the constrictor muscle of the pupil, and the latter, under the influence of the physical retraction of the radiated fibres, approaches nearer and nearer the ciliary border, and becomes more and more engaged within the corneal wound. If, however, we stimulate the iridian sphincter to contract by the contact of bright light, palpebral friction, a collyrium of ergot of rye, or slight applications of nitrate of silver to the external edge of the cornea, the pupillary border makes evident, and usually successful efforts to escape from its imprisonment. This continued pupillary contraction is also an obstacle to the reproduction of the accident. When the wound of the cornea is *quasi-central*, we proceed in exactly the opposite manner, inducing as complete a dilatation of the pupil as possible by sulphate of atropia, etc., in order to paralyze the iridian sphinc-

ter, and allow its radiated fibres to act by their own elasticity upon the pupillary border. (2.) In a less recent case (three days) we usually find that the portion of the iris protruding beyond the edges of the wound has become turgid, as it were erectile. This should be cut off close level with the cornea by curved scissors; and then we should try, by means of the probe, to reduce the portion remaining engaged within the wound, employing, at the same time, the means just mentioned for securing the contraction or dilatation of the iris. (3.) When the accident has become an old one (ten to fifteen days) all we can do is to treat the prolapsus itself by light and repeated applications of a fine pencil of nitrate of silver. The adhesions are too old to hope for anything short of a definitive fusion of the cornea and iris, and more harm than good would be the result of further interference.

2. When the solution of continuity is accompanied by loss of substance, we must take care not to reduce the prolapsus, for two peremptory reasons. In the first place, the hernia would be generally reproduced, and next, its existence is useful or even necessary, at first for the filling up that loss of substance the cornea is incapable of repairing, the aqueous humour incessantly carrying away the reparative secretion. It is, it may be observed in passing, as much in consequence of the absence of prolapsus of the iris as of the size of the perforation that corneal fistulae become established—fistulae which are almost always central, and which, if we will prevent the definitive loss of the eye, we must treat by the application of nitrate of silver to the lips of the wound. By this means, on the one hand, we induce contraction of the iris and the engagement of more or less of its pupillary border in the accidental aperture; and, on the other, the lips of the wound so treated secrete plastic matter in sufficient quantity to complete and solidify the reparation. We have first to save an eye so seriously threatened, and at a later period the prolapsus may engage our attention. In treating this M. Tavnogt has several times employed with advantage what he calls the mixed method, consisting sometimes in practising acupuncture at the base of the tumour, and sometimes rapidly cauterising its apex with nitrate of silver.—*Gaz. des Hôpitaux*, 1857, Nos. 87, 90.

#### EXCERPTA MINORA.

*Lotion for Strumous Glands.*—The following application neither stains the neck, nor annoys by its smell, while it acts with greater energy than the ordinary iodine ointments:—Dissolve ʒj. of iod. pot. in aq. dest. and eau de Cologne, aa ʒj. and spt. vini r. ʒvi. It is to be employed in frictions morning and evening.—*Omodei's Annali*, vol. clxii. p. 205.

*Cocoa-nut Oil Ointments.*—The cocoa-nut oil is a more eligible body for the formation of ointments than lard, keeping much better, not staining the linen, and admitting of more complete absorption. To render the oil of commerce fit for pharmaceutical employment, it is in general sufficient to liquefy it at a moderate temperature, and strain it through linen. But if it retains its peculiar odour too strongly, and is of too yellow a colour, it may be purified by digesting it for some hours in a water-bath, with some coarsely powdered vegetable charcoal, and filtering it while warm through paper. The following are some of the formulæ that have been tried with success:—℞ Iod. pot. ʒj., ol. cocos, ʒj; ℞ Ext. bellad. ʒj., ol. coc. ʒiiij; ℞ Veratrin, gr. iij., ol. coc. ʒiiij; ℞ Sulph. quin. ʒj., ol. coc. ʒj., ol. rosar. gt. x. (very useful in pityriasis capitis); ℞ Chlorof., ol. coc. aa ʒj. (of great service in neuralgic and rheumatic pains, rendering the chloroform more fixed, and its action more durable); ℞ Ol. terebinth., ol. coc. aa ʒj.; ℞ Hydr. ox. rub. gr. iv., ol. coc. ʒij.—*Omodei's Annali*, vol. clxii. p. 207.

**THE DENTAL BODY.**—The meeting of the Dental College, held on Friday, the 8th inst. to consider conditions of an amalgamation with the Odontological Society, was not very numerously attended. The advocates for the adoption of the preamble mustered strong to the right of the President. Many, eloquent, and warm were the arguments brought forward by these gentlemen; but the old Provisional Committee could not be induced to depart from the fundamental principles of the College upon which they were elected. The consequence was that the measure was lost, so that all chance of an amalgamation is for the present at an end.

## GENERAL CORRESPONDENCE.

### POISONING BY NUX VOMICA.

[To the Editor of the Medical Times and Gazette.]

SIR,—Thinking the two following cases of poisoning by the alcoholic extract of nux vomica may prove of some value, I send them to you for insertion in your Journal. Happily, similar mistakes seldom occur, and consequently there are very few of such cases on record; you will therefore, perhaps, consider them to be of sufficient interest for publication.

Dr. T., a retired Physician residing in this place, had suffered from partial paralysis, constipation, and distressing symptoms of vertigo for some time, and having tried different remedies in vain, went to London about six weeks since to consult Dr. George Budd, of King's College. Dr. Budd prescribed five grains of the extract of nux vomica with five grains of Barbadoes aloes, to be made into twenty pills with conserve of roses, and ordered one to be taken once or twice a day before meals. In order to get the extract pure, Dr. T. went to one of the best chemists in London to procure it. On his return from town he dispensed his prescription, but instead of putting a quarter of a grain of the extract into each pill, he put two and a half grains, with two and a half of aloes into each, believing that five grains of each had been ordered for a dose. In his practice I need hardly say the extract of nux vomica was never used, and he was not aware of the proper dose. After making up the pills, about a quarter before six p.m. he took a couple of them. His wife, who was present at the time, said that she had been suffering from headache all day, and that perhaps a couple would do her good also. Dr. T. consented, and gave her two, which she swallowed.

Shortly afterwards they partook of their tea, and felt no ill effects for rather more than forty minutes. Dr. T. then said that he had forgotten something in the garden, and that he would go and fetch it. He rose from his chair, and proceeded as far as his parlour door, when he felt the first symptoms, and exclaimed, "Hold me! Hold me!" Mrs. T. sprung from her seat, and ran to his assistance, but before she got to him, she also, as she afterwards termed it, "was fixed." The symptoms were most violent, and Dr. T. knew they were those of strychnia poisoning. Fortunately two of his sisters were in the room, and they immediately sent for me. Upon my arrival, within ten minutes of the first symptoms, I found that they had both of them taken an emetic of mustard and one of ipecacuanha, and antimony was procured from an adjoining druggist's shop, which they also took. On my entering the room I first saw Dr. T. in convulsive agonies, but perfectly calm and collected. I asked what was the matter; and he replied "Strychnia!" and his sister then told me the particulars of the London prescription. I then requested that he would tell me the dose which he had taken, when he said five grains of the alcoholic extract, and that his wife had taken the same quantity. I told him there was a mistake, but of course did not wait to examine into particulars, but ran to my surgery, and procured some sulphate of zinc, and immediately gave half a drachm to each. His pulse shortly after this was imperceptible at the wrist, and I gave him a drachm of the compound spts. of ammonia, and repeated it every ten minutes or so according as the pulsation rose or sank. The emetics acted quickly and powerfully, and Mrs. T. exclaimed after each evacuation from the stomach, "How bitter!" The convulsive spasms continued; there appeared to be an abatement of urgent spasm, but no positive cessation. They were both as it were fixed to the chairs on which they sat. The symptoms in both were exactly similar. As the convulsions came on, the heads were drawn back, there was a spasmodic clenching of the teeth, the heels fixed to the ground, and the eyes as if protruding from their sockets, and both curiously enough kept exclaiming, "Hold me! hold me!" although there was a person on either side of each. After the lapse of about twenty minutes I again gave half a drachm of the sulphate of zinc to each, with the same results, and repeated a third dose about the same time after the effects of the second dose had subsided. After about an hour and a half had elapsed from the first dose of the zinc, Mrs. T.'s symptoms became less urgent; the spasms weakened by degrees, and I with pleasure saw improvement in her every five minutes.

I have no doubt but that a large proportion of the extract was thrown from her stomach when she exclaimed "How bitter!" Dr. T.'s symptoms were still alarming, and I feared at one time there was little hope of saving him. I gave him a fourth dose of the sulphate of zinc, and it was not until this had begun to act that he too complained of the "horrid bitter." I of course gave most copious quantities of warm water, etc., during the action of the emetics, and had my stomach-pump in readiness to use if required; but I think any person who has once seen a severe case of poisoning by strychnia will acknowledge that it would be almost impossible to use the pump in these cases, the convulsive twitchings of the mouth, and the effect on the respiratory organs, rendering the operation so difficult and dangerous.

At the expiration of about two hours and a quarter after the first emetic, Dr. T.'s violent symptoms began to subside; at first the intermissions were of longer duration, although the spasms were equally violent, but by degrees they became less severe, and in about four hours they had entirely ceased, which made about five hours in all after taking the pills. I now asked him if he would get out of his chair, and make an attempt to walk, when he said that he still felt as if he was "fixed to his seat." He was then carried to bed, and afterwards suffered very little more than a person may be expected to after a severe fright. The next day he was down stairs, and the only thing he complained of was general debility and cramps in the calves of the legs. Mrs. T. suffered from prostration of strength for a week afterwards, and was confined to her bed. They are both now in their usual health.

I ought perhaps in justice to Dr. Budd to mention that I afterwards saw the prescription, and that the error was caused entirely in dispensing it.

Some of the symptoms in these two cases are I think very interesting, and particularly worthy of notice. Both patients took the extract at the same time, and they were both affected with the poison within two or three seconds of each other, both being immediately deprived of the power of walking.

In most cases of poisoning by strychnia the tetanic spasms are said to show themselves in from five to twenty minutes after it has been swallowed; in these two cases forty minutes elapsed before the muscular system became affected; much must therefore depend upon the state of the poison when taken, whether it be in solution or in the form of a pill. The peculiar state of the body being as it were "fixed" to the chair is very singular. Dr. T. afterwards told me, "that if I had set fire to a bundle of straw under him, he did not think he could have moved," although at the same time he kept crying "Hold me!"

The intellect in both cases was perfectly clear.

Dr. Christison mentions a case where three grains of the extract caused death, and Dr. Taylor also speaks of a case in his "Medical Jurisprudence" where fifty grains of the powdered nux vomica (equal to a quarter of a grain of strychnia), proved fatal.

I never before saw a case of poisoning by strychnia, but I can now well appreciate the decided and firm manner in which Dr. Taylor swore to the symptoms in Cook's case.

My friend and partner, Mr. Gardner, assisted me during these few hours of anxiety. I am, &c.

South Molton, 16th Dec. 1857.

R. LEY.

#### POLYPUS UTERI.—FISSURE OF THE RECTUM.

[To the Editor of the Medical Times and Gazette.]

SIR,—The following cases present certain points of practical interest:—

*Polypus Uteri, and its Cure by a Simple Operation.*—C. W., aged 37, had during the last four years suffered from constant hemorrhages, which were so severe as to cause syncope, and threatened death. When I saw her she had become anæmic and emaciated. On examination I discovered a polypus about the size of a small pear with a thick base attached just within the os uteri. On Nov. 27, I removed it in the following simple manner. I seized it with a pair of long valsellum forceps, and dragging it down into sight, passed through the base a needle armed with a double ligature of strong tissue, so as to tie in two parts. I then cut off the polypus just anterior to the ligature, and plugged the vagina with oiled lint; the whole operation lasting two or three

minutes. From this time there was no hæmorrhage, and in one week she was up and well. This was the first time for four years she had passed one week without hæmorrhage.

This plan, which I have practised and advocated for some years past, I consider much superior to either of the two plans generally adopted, viz., either simply cutting off the polypus, or the more tedious process with Gooch's apparatus, where the sloughing of the polypus within the vagina generally causes serious constitutional disturbance; not unfrequently pyæmia, and sometimes death.

*Fissure of the Rectum.*—Mrs. F., aged 36, married. Had been under different Medical treatment for many years for supposed inflammation of the uterus, and during the last attack she was confined to her bed for six months. She complained of a continual pain in the womb, with exacerbations of a very severe character. This had continued so long as most materially to injure her general health, and to compel her to relinquish a large and lucrative business in a provincial town. On examination I could find no evidence whatever either of inflammation or any other disease of the uterus. On further inquiry I ascertained that the period when the exacerbations came on was after defæcation, and that she was always obliged to lie down for some hours on account of its violence. I then examined the rectum, and discovered there a fissure, evidently of long standing, and some extent. I performed the usual very simple operation for its cure, and this, which only involved fourteen days' rest, completely relieved her, and all her pains disappeared. This took place three years since, and from that time up to the present she has not had a single return, and has enjoyed sound and robust health. The importance of this case consists in its showing the great necessity of considering all the points of a case, so as to form a correct diagnosis. I have seen a great number of cases, which have been treated for lengthened periods, of supposed disease of the uterus, which further examinations proved to be simple diseases of the rectum, and which were perfectly cured by simple means applied to this part.

I am, &c.

I. BAKER BROWN.

17, Connaught-sq., Hyde Park, 15th Dec. 1857.

#### VENTILATION AND MORTALITY AT THE GENERAL LYING-IN HOSPITAL.

[To the Editor of the Medical Times and Gazette.]

SIR,—I think that "after three weeks' study" you were entitled to a better reply from the Committee of the General Lying-in Hospital. The singular fairness of the reasoning, and careful abstinence from anything like unvarnished quibbling, betray a suspicious similarity to the style of Mr. Augustin Robinson, the undoubted author of that reply to Dr. Odling's letter, which for its misstatements (to say the least) is, as you well observe, "remarkable only for its inaccuracy." I shall, therefore, assume that the letter in your Journal of last week, signed by Thomas Henry Smith, Secretary, is by Mr. Augustin Robinson.

Let Mr. Robinson point out the statements "so utterly unfounded" which I have made, and which, as he asserts, have been "so often refuted." I shall be but too happy to retract whatever can be proved to be "unfounded," or capable of being "refuted."

Mr. Robinson still asserts that the ventilation, "from November, 1842, to February, 1843, inclusive," was "under Dr. Reid's system." This is simply untrue. I have repeatedly pointed out the facts of the case to Mr. Robinson himself, and they were unanswerably put to him by Dr. Odling in a masterly reply, which he does not find convenient to notice. The period alluded to was *not* "under Dr. Reid's system," inasmuch as the valves were almost constantly closed, and the ventilation annihilated.

Mr. Robinson refers to "a long report of Dr. Reid, dated February 21, 1843," and to a letter of my own, "dated February 14, 1843," in which we did not then allude to the closing of the valves; but, as both Dr. Reid and myself had written earnestly to the Committee on the unhealthy state of the wards in the previous November, in consequence of the valves being closed, I think it would have been more truthful to have noticed these communications. Mr. Robinson also alludes to a subsequent letter of mine (February 26, 1843), in which Dr. Rigby "attributed the outbreak of puerperal fever to the closing of the valves of the upper back ward

during one evening; but in neither letter does he allude to any systematic closing of the valves by the nurses." And so, forsooth! because I directed the attention of the Committee to one gross case of misconduct, an unvarnished quibble is attempted to be set up that it was a solitary instance, and had not been constantly repeated on other occasions.

The fact of eleven deaths having occurred during 1855, after the ventilation was renewed in May of that year, merely shows that it was not carried on with sufficient force to neutralize the infecting properties of the walls, etc., well saturated with miasm during five previous years of non-ventilation. I acknowledge that this was in some degree my own fault, and that it was unwise to try and ascertain what was the minimum of fire necessary for maintaining the ventilation just after the Hospital had been under the influence of non-ventilation for five years. We may take it as a law in ventilation, as you yourself have rightly observed, that where a change has been made the effects of the previous system continue to show themselves on the health of the patients for six months afterwards. Thus, in 1850, after seven years of ventilation, although 157 patients were delivered in the Hospital during that year after the discontinuance of the ventilation in April, not a single patient died; whereas, in 1855, after five years of non-ventilation, eleven patients died between May, when it was renewed, and the end of that year; and this number was, I fear, rendered larger than it otherwise would have been by my anxiety to reduce the ventilation to its minimum, and thus remove any ground for complaint on the score of expense. The entire cessation of deaths in April, 1843, immediately on active ventilation being established, was because the Hospital had been reopened only twelve months previously, the walls, flooring, paint, white-washing, and bed-furniture were all new and fresh, and it only required the necessary amount of fresh air to put matters right.

I could go on to refute every little subterfuge and unvarnished quibble which Mr. Robinson has had recourse to, but surely it would neither be worthy of the space in your columns or the time of your readers.

I again repeat my assertion, that Mr. Grisell "ordered a large hole to be made into the fire-shaft, by which its action on the air of the Hospital was effectually cut off, and this he did without having such a measure moved or seconded, or put to the Committee in the regular way, and in spite of the disapproval of the Senior Physician (myself), who was standing by." This wanton destruction of the ventilation was, therefore, not "resolved by the Committee," nor is it fair to foist the delinquencies of wrong-headed, ignorant men upon the Committee, who are decidedly not responsible for them.

Let Mr. Robinson explain why he endeavoured to mislead Dr. Odling, by asserting that the death-rate during the ventilation was 1.68 per cent., and without the ventilation only 1.69 per cent. Let him explain, if he can, the means he made use of to obtain so remarkable a result. Let him contradict, if he can, a single number in my whole table of deliveries and deaths. These are neither small numbers, nor occurring during short periods of time. The numbers are large, and extend over so many years, as to obviate all cavil as to chance, accidental circumstances, or my "statements so utterly unfounded, and so often refuted!"

It is monstrous to suppose that the death-rate of a large Lying-in Hospital is to be wantonly increased nine and a half times more than when under the influence of a system of active ventilation, as explained to the Committee by Dr. Odling; and I sincerely trust that your remarks on "the great Lambeth Matricide," as you have called it, will have the effect of ultimately bringing the authors of it to a just account. I am, &c. EDWARD RIGBY, M.D.

Late Senior Physician to the General Lying-in Hospital.

Berkeley-square, Jan. 13, 1858.

### MAMMARY GLANDULAR TUMOURS.

[To the Editor of the Medical Times and Gazette.]

SIR,—In the Journal of the 7th ult., vol. xxxvi., at page 487, there is a report of a meeting of the Pathological Society, held Nov. 3, at which a specimen was exhibited by Mr. S.

Wells, called "Malignant Glandular Tumour of the Mamma."

With your permission, I am anxious to publish a few observations on this morbid specimen, and the case it illustrates, especially as it has already formed the subject of a communication in the number of your Journal, April 11, 1867, vol. xxxv. p. 359.

The specimen is described to be "important, as it proved that a tumour which might be classed with the mammary gland tumour of Paget, and the hypertrophy of Lebert, a tumour usually regarded as innocent, might show its malignant tendency by being followed by secondary deposits." Now, it is very remarkable that neither in this report, nor in the paper by Dr. Aitken, is there any description of a "mammary glandular tumour" to be found. "Mr. Quekett made a careful examination of the primary tumour on the day it was removed;" and the report states, "The gland substance had been converted into a uniform tumour. The epithelial cells lining the ducts and the sac-like dilatations at their extremities were altered into every variety of form; they were granular, and very abundant, so that they distended the ducts and burst them in some parts." (a)

From this description, it is quite evident that the tissues and structure of the gland itself had undergone a morbid change, by which the breast became "converted into a small, hard, moveable, uniform tumour." It was, in fact, a disease of the breast, and not a new growth developed on or between its lobes.

Mr. Quekett's description of the morbid specimen, therefore, clears away all doubt as to the existence of a "mammary glandular tumour."

Considerable ambiguity is produced by the employment of the word "tumour" to express the morbid condition existing in this case. "Mammary glandular tumours" are circumscribed, defined and distinct new growths of structures, resembling, more or less closely, the original gland tissue, and are so perfectly characteristic, that such a morbid state of the breast as that described by Mr. Quekett can never be classed with them.

Strictly confining the word "tumour" to signify a new growth, it is not applicable to the morbid change observed in the case under examination; for Mr. Quekett describes no other structures than those which compose the normal organ. He remarks upon the "gland substance," the "epithelial cells lining the ducts, and the sac-like dilatations at their extremities," in other words, their caecal terminations. An abnormal quantity of epithelium existed; but I cannot find a single word implying that a new growth or tumour existed.

The report further states, "There was not one of the characteristics of scirrhus on section."

Assuming that the primary disease in this case was carcinoma there are very cogent reasons why there were none of the characteristics of scirrhus to be seen. In point of fact scirrhus is only an advanced stage of infiltrating carcinoma, whilst in this case, as the subsequent history demonstrates, we have an example of the earliest stage of this disease.

The morbid state of the gland tissue described in this instance is not very uncommon in some forms of infiltrating carcinoma of the breast, when either the entire organ is affected or only some of its lobes. Even around a scirrhous carcinoma of the breast the true or proper gland tissue of the organ around this disease frequently exhibits the minute elementary structures so well described by Mr. Quekett in this instance.

I do not, therefore, for one moment call in question the account of the diseased gland by Mr. Quekett. It describes, exactly, that which I have myself repeatedly seen in the examination of breasts similarly affected and removed from patients whose subsequent history was identical, in every particular, with this case of Mr. Wells.

But I do most strongly dissent from the proposed classification of the case as published in your report, because it must of necessity lead to a fundamental error in pathology, and to the association of two of the diseases of the breast as utterly dissimilar in their morbid anatomy as in their natural history.

Therefore, we have yet to learn that "a tumour, usually regarded as innocent, might show its malignant tendency by being followed by secondary deposits."

January, 1858.

I am, &c.

JOHN BIRKETT.

## APNŒA OF NEW-BORN INFANTS.

[To the Editor of the Medical Times and Gazette.]

SIR,—The above subject having been handled in your Journal by Dr. Silvester and other correspondents in discussing the Ready Method for the Treatment of Asphyxia, perhaps you may deem the following observations worthy of insertion.

When a healthy child is born air passes into the lungs under the influence of two forces, first the elastic recoil of the ribs when escaping from the pressure of the vagina; second, and this is the principal agent, the inspiratory muscular effort excited by the new impressions on the cutaneous nerves, especially by cold. Sometimes breathing does not so readily begin, but on lifting the child, and giving it a small slap on the back, it commences. No doubt this proceeding (as also the alternate dashing with warm and cold water), acts through the medium of the cutaneous nerves in rousing reflex action, but I believe we often unconsciously bring another principle to our aid.

If any one will lift the body of a dead infant, by placing one hand under the back or loins, and allow the weight of the head and arms on the one side, and of the legs on the other to extend the spine, he will find that the ribs separate from each other, the capacity of the chest increases, and air enters the lungs. On again supporting the body, turned over, with the hand under the abdomen, the process is reversed, the spine is flexed, the ribs approximate, and air is expired. The smart slap on the back may act by causing extension of the spine, partly the effect of the blow, partly by the contraction of the erector spinæ thus excited, with the consequent separation of the ribs, expansion of the chest, and entrance of air.

Again, in our anxiety to lay down new rules, we ought not to lose sight of the old and tried method of throwing air into the lungs through the nose of the infant by means of our own breath. The prone position is here unnecessary, there is no water to run from the pharynx; by one movement of the finger we clear away mucus, and hook forward to the base of the tongue; the elasticity of the epiglottis and hyoid apparatus will keep the air passage free.

When air has passed into the lungs, or has been blown in, but respiration does not continue, I have successfully adopted the following method in two or three cases, (in one which occurred to me about seven years since, the child had lain supposed to be dead for about half an hour,) having placed the lower half of the child's body in a warm bath, for I cannot believe that we should be right in allowing the body to cool outright, and there is surely some difference in the case of an adult taken from cold water, and an infant coming from a cavity having the temperature of 100° Fahrenheit; placing, I repeat, the lower half of the child's body in warm water, and causing its face and chest to be occasionally dashed with a sponge saturated with cold water, I put my two thumbs close together on the spine, between the angles of the scapulæ, and spreading out the fingers like a fan over a large surface of the chest, I found it easy not only to support and regulate the position of the body, but to cause a movement of expiration by pressing the ribs inwards and downwards, and of inspiration by extension of the spine, the clavicles being raised and the shoulders thrown back by the pressure of the forefingers, the thumbs making counter-pressure against the spine forwards. A rhythmic movement, timed by the operator's inspiration, is thus kept up with facility as long as required; when the infant makes an inspiratory effort it is immediately felt; and aid can be given or withheld as appears desirable.

The proceeding just described is probably not new, but it is so easy and effectual, that any one who has once learned to put it in practice will not be readily induced to change it.

I am, &amp;c.

JAMES MORRIS, M.D. Lond.

Park-street, Grovesnor-square, December 5, 1857.

## ON THE CAUSE OF DENTAL CARIES.

[To the Editor of the Medical Times and Gazette.]

SIR,—Unfortunately I have not had the advantage of reading the article upon Saliva by Dr. John Smith, published in 1852, as it might have expanded my views and enlightened my understanding upon that important question. It is also just possible that if the Doctor had read some of my former

publications upon the cause of caries of the teeth, he would have seen that we differ very little upon the subject, as I am quite aware that normal saliva is unquestionably a preservative to the teeth, and that it is from the circumstance of the continual presence of a pool of saliva on the inside of the lower incisors that those teeth in the majority of cases enjoy immunity from the attacks of caries. But by the same rule this pool of saliva, even in cases where it is abnormal, is rendered less destructive on account of its quantity, as that quantity liquifies and holds in solution the salivary, or as it is frequently called, the buccal mucus, which substance is found to exist to excess in the mouths of patients whose teeth are being destroyed by caries; the saliva in such cases being highly acidulated, clammy, stringy, and viscid. It may also be observed in such cases that when silver plates for artificials teeth are inserted over decayed stumps a short time only elapses before the plate is destroyed (perforated) where it rests on the stump, in consequence of the galvanic action which is exerted betwixt the metal, the roots, and the fluid; indeed, so much do I coincide with the Doctor's views, "that normal saliva is a preservative to the teeth," that were he to refer to the *Medical Times and Gazette* of Oct. 28th, 1855, he would find that I recommend a wash for this very purpose, "compounded to resemble an excess of healthy saliva." That caries of the teeth is the result of external chemical agency, is now being recognised by all dentists on both sides of the Atlantic, is evident enough, but a wide field is still open for the physiologist to explore, so that any practical remarks upon the subject, I may venture to say, would be gratefully received by all who practise the Profession. But should Dr. Smith feel disposed to favour us, I would advise him, firstly, to inquire amongst, and procure from practical dentists any section of human teeth which have "indicated" any carious spot in the substance of the dentine to which there does not exist an opening from the peripheral portion of the tooth. Could any such specimens be procured and forwarded to me, I should be happy to lay them before the College of Dentists, although they would form an argument against a theory which I have nursed for fifteen years or more, not, I hope, dogmatically, but, as I conceive, from the result of observation in practice.

I am, &amp;c.

Savile-row.

DONALDSON MACKENZIE.

## FEES.

[To the Editor of the Medical Times and Gazette.]

SIR,—As I have lately taken part in a discussion on the subject of the Physician's and Surgeon's fees, will you allow me to state, through the medium of your Journal, that I think the ordinary fee of a guinea is ample in ordinary cases, even although the patients are seen for the first time. My argument is to show that in some cases—very long consultations, for instance—the medical man ought to be at liberty to name a higher fee than a guinea.

January 11, 1858.

## MR. SYME AND HIS COLLEAGUES.

[To the Editor of the Medical Times and Gazette.]

SIR,—It is too true that, as you say, the printed papers of Dr. Laycock contain abundance of "mean quibbling," "unworthy subterfuges," and "positive deviations from truth." But whether the odium of this should be attributed to Dr. Christison, who has so long been distinguished by scrupulous correctness of conduct, the strictest honour, and the most unimpeachable integrity, or to the protégé of Dr. Simpson, is a question upon which the opinion that you have expressed may perhaps not be universally entertained. (a)

Dr. Christison's letter was returned by the gentleman to whom it was addressed, in order that he might correct an error pointed out by himself. You quote from the original letter, which, in accordance with honourable feeling and the usage of society, should have been considered as no longer in existence; and you hold up the author to scorn for calling attention to an inaccuracy which it contained. This inaccu-

(a) We expressed no opinion: we only expressed sorrow and astonishment.—Ed.

racy, to say nothing of a date that did not affect the question at issue, was merely that I had "read," instead of "stated," the terms of agreement which Dr. Laycock accepted, and afterwards repudiated.

I am, &c. JAMES SYME.  
2, Rutland-street, Edinburgh, Jan. 12, 1858.

### ON THE ACTION OF THE VALVES OF THE HEART.

[To the Editor of the Medical Times and Gazette.]

SIR,—Will Dr. Brinton, in explanation of his letter on the action of the valves of the heart, inform me, and, as I believe, nearly the whole Profession, where the action of auriculo-ventricular valves is explained as simply as in the report of my demonstration in your Journal of the 26th of December, 1857? It makes one appear rather foolish, to show as new what others have previously shown; but I ask your readers' indulgence, as it was not only new to me, but to such men as Billing, Carpenter, Richardson, Leared, Lane, Tatum, and every one to whom for years past I have spoken on the subject. Moreover, the written opinions of Carpenter, Kirkes, Paget, Quain, Bellingham, and our principal authors on diseases of the heart, are at variance with my explanation; nevertheless it may well be that I am not the first who has observed and recorded this simple but beautiful fact; that is of very little moment, provided the fact be known and duly appreciated; for it gives us a starting point in the heart's action, it tells us that distended ventricles imply closed valves, and that previous to the contraction of the ventricles, there is a perfect septum between the auricles and them. This, I admit, is something to know, and, what is more, to make known, whoever may have first observed it.

But does Dr. Brinton quite understand the report in your Journal? For he has strangely confounded the simple hydraulic test I proposed in imitation of Nature, with a mode he has adopted of injecting the ventricle from the apex. Let me state what I believe to be the manner of the closure of the auriculo-ventricular valves in health. The auricles contracting on the blood, the force of their contraction is transmitted by the blood in all directions, separating the flaps of the valves, distending the ventricles, and (the semilunar valves being shut down) pressing as much upwards and backwards, as downwards and onwards. The force, not being sufficient to raise the semilunar valves, is expended in distending the ventricles, and raising and closing the auriculo-ventricular valves.

Now it is evident, the matter being purely physical, that in order to test the efficiency of these valves after death, we must put the ventricle in the same condition as it is in during life, that is, empty, and with the semilunar valves tightly shut down; our force also must be exerted in the same direction, i.e. a fluid being poured in through the auriculo-ventricular opening, the valve, if healthy, will be raised in proportion as the ventricle is filled, so as to form a perfect septum between auricle and ventricle. How far this applies to diseased valves it becomes those who have more opportunities than I to determine. Should the semilunar valves be found so diseased as not to admit of forcible closure by fluid, the aorta or pulmonary artery, as the case may be, should be tied on a cork inserted into it before the mitral or tricuspid valve is tested.

I am, &c.

17, Victoria-square.

GEORGE B. HALFORD.

P.S.—Since writing the above, I find Valentin is the author alluded to by Dr. Brinton, and himself, I suspect, the teacher. I thank Dr. Brinton for the information. Valentin is perfectly right as regards the closure of the auriculo-ventricular valves; we only differ in the mode of showing their action. As regards the examination of the valves after death, I much prefer the mode I have proposed to that of Dr. Brinton, for the reason that it is simpler, and hence more perfect.

ROYAL MEDICAL BENEVOLENT COLLEGE.—We have much pleasure in stating that the Right Hon. Lord Stanley, M.P., has kindly consented to preside at the sixth festival of this institution, which will take place in March next. The particular day for the festival will be duly announced in our advertisement columns, so soon as the necessary arrangements are completed.

## REPORTS OF SOCIETIES.

### HARVEIAN SOCIETY.

JANUARY 7, 1858.

ALEXANDER URR, Esq., President, in the Chair.

### ANNIVERSARY MEETING.

THE Council's report was read, showing a healthy state of the funds of the Society, and a steady increase in the number of Members. Many valuable papers had been read during the past session and discussed with ability, and that perfect courtesy and harmony, which is quite compatible with differences of opinion. The Society and its individual members were much indebted to the Medical press for the publication of their proceedings, by which their reputation was extended, and the advantages of the Society to its members and the Profession made more known. The following gentlemen were elected officers of the Society for the year 1858:—

President.—G. Hamilton Roe, M.D.

Vice-Presidents.—John Birkett, Esq., F.L.S.; J. E. Pollock, M.D.; E. H. Sieveking, M.D.; E. Hart Vinen, M.D., F.L.S.

Treasurer.—H. Wm. Fuller, M.D.

Honorary Secretaries.—Weedon Cooke, Esq.; Graily Hewitt, M.D.

Council.—H. A. Aldred, M.D., W. H. Allchin, M.B., T. J. Ashton, Esq., T. Ballard, Esq., R. H. Goolden, M.D., E. Headlam Greenhow, M.D., G. Reece, Esq., J. Burdon Sanderson, M.D., H. C. Stewart, Esq., H. Thompson, M.B., Haynes Walton, Esq., Charles S. Webber, Esq.

Mr. BALLARD exhibited the

### LARYNX AND TRACHEA OF A CHILD

who had died of croup. It had been treated by Dr. Hastings, who sponged the larynx with caustic. Mr. Ballard consulted with Dr. Fuller as to the expediency of tracheotomy, which was not considered desirable. The child died, in Mr. Ballard's opinion, from asphyxia, the right side of the heart being full of blood. In a similar case, in which leeches were applied, the patient recovered.

Dr. FULLER referred to a case in which there was a large scrofulous tumour in the trachea, accompanied with a croupal sound during expiration, in contradistinction to the inspiratory sibilation of genuine croup, and had given his opinion against operation in Mr. Ballard's case, owing to the presence of this symptom.

Dr. POLLOCK related a case of epithelial growth from the trachea, and exhibited the late Mr. Avery's beautiful speculum and lamp for examining the orifice of the larynx.

Dr. CAMPS wished to know what caustic was used by Dr. Hastings.

Mr. BALLARD did not know, and rather attributed the ill effects of mopping the larynx to the mechanical injury produced by the sponge.

Mr. BROWNING exhibited the

### LUNG OF A MAN,

aged 50, who died from the poisonous effects of six drachms of essential oil of almonds. He walked down stairs after taking the poison, spoke to his son, and lived about ten minutes. The lungs were remarkably emphysematous, the air-cells being distended into bladders. The heart was full of blood, and the foramen ovale open.

Dr. SANDERSON read a paper on the

### NOSOLOGICAL CHARACTERS OF THE YEAR 1857.

The author introduced his subject by remarking that fifty years ago more attention was paid to the modifications which acute diseases undergo from time to time in their general characters than at present. This he attributed to the comparative disregard of prognosis, or that part of medicine which relates to the common or variable characters of acute diseases, in favour of diagnosis, or the study of those constant or special characters by which one disease is discriminated from another. Reference was made in illustration to the opinion of Dr. Bennett, that disease is invariable, and consequently that the same diseases have at all times required the same treatment; and to the controversy at present in existence between the Edinburgh Professor and those who adhere to the doctrine

of Sydenham. The author endeavoured to show—1. That since the end of the last century diseases have undergone two great modifications; that at the beginning of a period of twenty years, terminating in 1805, the inflammatory and febrile diseases exhibited much the same characters as at present, venesection being usually injurious, and active antiphlogistics not being required, or even tolerated; that towards the end of that period the aspects of disease so completely altered, that the very men who had before advocated the opposite practice were compelled to bleed repeatedly, and that not only for internal inflammations, but in continued fever. Since that period, and particularly since the year 1830, a “constitution” has prevailed which is marked by the greater prominence in inflammatory and febrile diseases of symptoms referable to the nervous system. 2. That in refraining from bleeding in 1800, in again having recourse to the lancet in 1820, and in gradually laying it aside since 1830, the Profession has acted throughout on the same principles, these not being founded on speculations as to the nature of inflammation, but derived from observation of the mode of fatal termination of the disease, and of the effects of the remedy on those constitutional states which were found by experience to be most dangerous. The year 1857 was described as favourable to the public health, the mortality having been 6 per cent. below the average. It was shown that this diminution was entirely referable to those classes of disease which are supposed to depend on local causes of unhealthiness, the fatality of pulmonary affections having been greater than usual. The diarrhoea of 1857, which was fatal to 1000 persons in excess of its usual average, was traced in its rise, progress, and decline; and a comparison was drawn between the summer diseases of the present time, and those which prevailed before the first advent of cholera; the summer diarrhoea of this period was of a different character from that which now exists; as a cause of death it was so inconsiderable as not to produce any sensible effect on the mortality of London; and although since 1830 it has existed in its present form every summer, it did not attain more than one-third of its present prevalence until after 1846, the outbreak of that year being 150 per cent. in excess of the previous average, but nearly 40 per cent. below that of 1857. The rest of the paper was occupied with a notice of the epidemic catarrh which prevailed throughout London in November. Reference was made in conclusion to the subject of Diphtherite, respecting which interesting communications were read from Medical men in Devon and Cornwall descriptive of local epidemics of that disease.

Mr. CLEVELAND considered that the large importation of foreign fruit of late years had contributed to the increase of diarrhoea.

Dr. POLLOCK doubted whether the type of disease had changed. We have changed our treatment, but the disease remains the same that Sydenham wrote of. The thermometer would always indicate why diarrhoea increased or diminished.

Dr. QUAIN dwelt upon the importance of the question, whether the constitution was the same now as it was when bleeding was in vogue. As an instance of the asthenic nature of disease now, he mentioned the rareness of rusty expectoration in the pneumonia of late years, and said that cuppers complain that they have lost those patients who used spontaneously to resort to them, which fact showed that the public feels its altered constitution.

Dr. CAMPS related the case of a gentleman who was accustomed to periodical cupping, and who, by its practice, was made paraplegic. Dr. C. thought that the anxieties attending our present mode of life, with its fierce competitions, caused disease to assume a nervous character, and that railway travelling had a similar effect. He had seen many country patients whose lives had been sacrificed by too much bleeding.

Dr. SANDERSON having replied, the Society adjourned.

**ACCIDENTAL DEATH FROM POISONING.**—The *Moulmein Advertiser* records the melancholy death from poison of Mr. J. C. K. Bond, Assistant-Surgeon on the Madras Medical Establishment. The doctor returned in the best possible health from a friendly visit to a neighbour, and previous to retiring to rest took what he supposed to be two blue pills, but which unhappily proved to be pills containing a grain of strychnine each, prepared for the destruction of pariah dogs.

## EPIDEMIOLOGICAL SOCIETY.

MONDAY, JANUARY 4, 1868.

Dr. SNOW, in the Chair.

Dr. McWILLIAM read a paper by FREDERICK H. JOHNSON, Esq., Bishopswearmouth, on the

### CAUSES WHICH INFLUENCE THE ARREST OR SPREAD OF CHOLERA.

The author commenced his paper by expressing the opinion that if cholera did not become a disease indigenous to this country, it was at least probable that the intervals between its visitations would be shortened, and on each occasion would disseminate more widely its influence upon the bills of mortality. It was, therefore, desirable, as a question of pathological interest, and as one upon the settlement of which some groundwork for the establishment of definite sanitary laws might be raised, that more harmonious opinions should prevail among the Profession than at present regarding the origin and propagation of this terrible scourge.

Mr. Johnson stated that the facts upon which his paper is based were the result of observations made at Sunderland during the three occasions on which that sea-port town was invaded by cholera, viz.:—

In 1831-2; 1848-9; 1853-4.

In the 1st period there died 202; or 1 in 200 of the population.

In the 2nd period there died 359; or 1 in 185 of the population.

In the 3rd period there died 28; or 1 in 2,230 of the population.

Mr. Johnson is of opinion that on each of these occasions the first case of the disease was imported by shipping, and that the subject of the disease had first arrived in port from Hamburg. The main object of the paper being to show how far personal intercourse influences the propagation of cholera, Mr. Johnson observes, that in every instance at Sunderland a case has been imported from a remote infected district, and proved more or less fatal to persons in direct communication with it; but that an interval has always existed during which the cases were more or less solitary, before the epidemic or spontaneous eruption took place; that the course of the epidemic has been gradually acquiring a maximum intensity, and then frequently resolving itself finally into the scattered groups with which it commenced; and that not unfrequently during the decline of the disease the seizures were solitary and unconnected, and when always among the most severe, Mr. Johnson continues, numerous examples were furnished in the course of these epidemics in which the transmission of the malady could only be explained on the supposition of its contagious nature. Mr. Johnson then proceeds to relate a series of outbreaks of cholera in isolated groups, where on every occasion the cause is traceable to the agency of immediate or intermediate contagion; adding that, so far as his personal experience goes, with the exception of one solitary instance, when the subject was of imbecile intellect, he has never yet had a case of cholera brought under his notice in which he was not able to refer the cause, more or less circumstantially, to pollution from personal communication. Mr. Johnson offers some instructive remarks on the effect of density of population and drainage in influencing the mortality of cholera and other epidemics; and concludes by an interesting account of the precautionary measures he adopted against cholera, while in the sanitary charge of the river Wear and its shipping during the epidemic of 1853; and also of the means of prevention had recourse to on the same occasion in the town of Sunderland, by a united and unanimous Board of Health, composed of the Town-council and the Board of Guardians.

Dr. SNOW said that the account was very gratifying which the author gave of the benefit arising from the Medical inspection of the ships and crews arriving at Sunderland from ports infected with cholera. This kind of inspection cost very little, and did not interfere with commerce. If the Medical Profession should become satisfied that the importation of cholera could be prevented without a tedious quarantine, the opposition to admitting its infectious nature would soon cease. The great injury which strict quarantine would do to this nation, and the ruin it would entail on particular interests, was a great obstacle to the general admission that cholera was

a communicable disease. He did not mean that individuals knowingly shaped their opinions for these reasons, but that they were unconsciously influenced by them. Mr. Johnson had related a number of instances in which cholera was undoubtedly propagated by close proximity with, and attendance on the sick, and some cases where the disease was communicated by the soiled linen and other wearing apparel of the patients; and it was fair to conclude, in the absence of any other known cause, that all those cases of cholera which arose without any proximity to a sick person or his clothes were also caused by the same *materies morbi*. It seemed that the morbid matter of cholera was not only capable of acting by near proximity, like that of syphilis, but was capable also of being conveyed to a distance, like the matter of small-pox. The remarks which the author of the paper made with regard to the water-supply of Sunderland confirmed the statements which he, Dr. Snow, had previously made to the Society. In this town, which had a supply of water free from the possibility of contamination, the cholera, in 1853, was almost confined to a few imported cases, and a few persons who came in immediate contact with these cases; while in Newcastle, where it was acknowledged that a great part of the population were supplied with water containing some of the sewage of the town, there was a fearful epidemic of the disease.

Dr. WALLER LEWIS said that he thought most men were now coming to the conclusion that contagion must be one of the causes contributing to the spread of cholera.

Dr. CAMPS objected to the use of the term cholera-germ. The existence of any such germ was a pure assumption.

Mr. SPENCER WELLS said, he hoped great practical good would result from the paper of the evening. Repeated attempts had been made to rouse the Government from their culpable indifference to the importation of cholera. The disease had prevailed epidemically in some north-eastern parts of the continent, in Hamburg especially, before each epidemic in England; and the first cases here had not only followed the arrival of ships from infected ports, but the actual arrival of patients suffering from the disease in those ships. It was a heinous crime to permit those patients to endanger the whole population of this country when it would be perfectly easy to have a house in some healthy locality at every port to which sufferers or suspicious cases could be removed immediately after the arrival of any vessel. Medical inspection of the vessel, and crew and passengers on arrival, are all that would be necessary, and he (Mr. Wells) trusted that an authoritative representation from the Society would be made to Government, warning them of the danger of neglect, and the facility of taking due precaution without any undue interference with commercial interests.

Dr. WALLER LEWIS and Dr. M'WILLIAM spoke in favour of this suggestion, and it was arranged to bring this subject before the Council at the next meeting.

Dr. SNOW announced that at the next meeting of the Society, to be held on Monday, February 1, a paper on "Drainage and Water Supply, in connexion with Public Health," would be read by Dr. Snow.

## MEDICAL NEWS.

**ROYAL COLLEGE OF SURGEONS.**—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted Members of the College at a meeting of the Court of Examiners on the 8th inst. :—

ALLEN, JOHN, Malta.  
BEALE, GEORGE BEWSHER, Finsbury-square.  
BROOKS, ARTHUR D'OYLEY, Henley-on-Thames.  
COLAHAN, JOHN JOSEPH A., Dominick-street, Galway.  
CRAWFORD, MICHAEL RICHARD R. H.E.I.C.S. Calcutta.  
LATHAM, ALFRED WILLIAM, Nantwich, Cheshire.  
MEDCALF, GEORGE, Ball's-pond-road, Islington.  
M'IVER, JOHN, Silver-bridge, county Armagh.  
NEEDHAM, FREDERICK, York.  
SMITH, WILLIAM HENRY, Houghton-le-Spring.  
STOCKER, EDWARD CLEMENT, Congleton, Cheshire.  
TAYLOR, JOHN, Woodstock, Oxfordshire.  
THOMPSON, JAMES CHARLES, Army.

## DEATHS.

ALLEN.—On the 9th inst., John Stewart Allen, Physician and Superintendent Joint Counties Lunatic Asylum, Abergavenny. M.R.C.S. Eng. 1833; L.S.A. 1838; L.R.C.P. 1844.

BYWATER.—On the 3rd inst., at Knottingley, William Bywater, M.D., aged 67.

KNAPP.—On July 1, Dr. J. M. Knapp, Residency Surgeon, Indore, murdered by the Indore mutineers.

ROWELL.—On the 12th inst., at Lead Gates, near Matfen, John Rowell, aged 23.

WHITEN.—On the 6th inst., at Burnley, in consequence of a fall from his horse, Stephen Elworthy White, M.R.C.S. Eng. 1825; L.S.A. 1824.

## APPOINTMENTS.

Dr. V. PINALI has been appointed Professor of Clinical Medicine in the University of Padua.

Dr. JOSEPH MEYER, a gentleman of the Jewish persuasion, now Assistant to Professor Schönlein, has been appointed by the Prussian Government to the higher post of Director of the Syphilitic Department at the Charité Hospital.

Dr. J. G. WESTMACOTT has been elected Medical Officer to the Paddington Provident Dispensary, in the room of Mr. J. W. Howard, resigned. Jan. 6th, 1888.

Her Majesty has been pleased to appoint Thomas Manners, Esq., to be Surgeon to the Penal Settlement in the Colony of British Guiana.

**POCKET-BOOK AND DIARY.**—We have received a copy of a very serviceable little book, called, the "Metropolitan Pocket-Book and Diary," which, for information and careful classification, surpasses anything we have yet seen in reference to the operations under the Metropolis Local Management Act. The list of Medical Officers of Health, Inspectors of Nuisances and Sanitary Commissioners will prove most useful, as showing at one view the names of all officers under the same class in the various parishes and districts.

**CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, VICTORIA PARK.**—The annual general court of the governors of this institution was held yesterday at the London Tavern. It appeared from the report presented that the new cases relieved as out-patients during the last year had been 6228, and there had been an average attendance each week of 908; 308 cases had also been under treatment as in-patients. The receipts had amounted to £6278. 16s., and the expenditure for maintenance £4720. 17s. 3d., and for building and furnishing £1262. 7s. Legacies were reported to the amount of £1113. 10s. 2d. His Royal Highness the Duke of Cambridge, it was announced, had consented to preside at the forthcoming festival, and it was hoped that great endeavours would then be used to increase the funds, so urgently needed to maintain the increased operations of the charity.

**MUNIFICENT BEQUESTS.**—In consequence of the recent decease of the widow of the late Mr. John Hinchliffe, of Notting-hill, there are now being paid over the following princely bequests to metropolitan charities:—The Cancer Hospital, £1000; Charing-Cross Hospital, £1000; Middlesex Hospital, £1000; St. Mary's Hospital, £1000; Asylum for Idiots, £1000; Westminster Hospital, £1000; Magdalen Hospital, £1000; Lock Hospital, £1000; London Fever Hospital, £1000; Indigent Blind Asylum, £1000; Deaf and Dumb Asylum, £1000; London Truss Society, £1000; Journeymen Tailors' Institution, £1000; Houseless Poor Society, £500; and Society for Prevention of Cruelty to Animals, £500; making a total of £14,000. The late Sir C. M. Clarke has bequeathed upwards of £1500 to Medical and other charities.

**SIR JAMES FELLOWES, M.D., F.R.S., L. and E.,** Inspector-General of Military Hospitals, whose death we recorded last week, in his 86th year.—The deceased served on the continent in 1794; was at the siege of Cadiz, and at the battle of Barossa under General Graham, afterwards Lord Lynedoch, and received the Peninsular war medal and clasp for Barossa; he was knighted by George III. for his general services, especially at Gibraltar during the pestilential fever in 1804-5. He was one of the English who were confined in the Temple during the revolutionary period in Paris. On his retirement from the service he was honourably mentioned by the Lords

of the Treasury in a minute dated March 3, 1815. He was Senior Fellow of the Royal College of Physicians, and a Magistrate and Deputy Lieutenant of the county of Hants. Sir James was elder brother of Admiral Sir Thomas Fellowes, who died in 1853.

ON Tuesday evening last a large and respectable audience attended the Debating Society's meeting, which assembled in the Upper Room at Wylde's News Room, Leicester-square, to discuss the following question:—"Should this meeting aid in checking the moral, social, and sanitary evils of prostitution?" After an animated debate of four hours, which elicited many important facts, opinions, and suggestions, the question was put from the chair, and carried in the affirmative by a large majority.

**STARVATION POINT.**—If we cannot with any precision say how long starvation will be in effecting its fatal end, we can say how much waste is fatal. From the celebrated experiments of Chossat on inanition it appears that death arrives whenever the waste reaches an average proportion of 0.4. That is to say, supposing an animal to weigh 100lb., it will succumb when its weight is reduced to 60lb. Death may of course ensue before that point is reached, but not be prolonged after it. The average loss which can be sustained is 40 per cent.; sometimes the loss is greater, especially if the animal be very fat; thus, in the Transactions of the Linnæan Society a case is reported of a fat pig which was buried under 30 feet of chalk for 160 days; his weight fell in that period no less than 75 per cent. Curiously enough, as an illustration of what was just said respecting time not being an index, fishes and reptiles were found by Chossat to perish at precisely the same limit of weight as warm-blooded animals, but they required a period three-and-twenty times as long to do it in; thus, if the experiment be performed of starving a bird and a frog during the warm weather, although both will perish when their loss of weight reaches 40 per cent., the one will not survive a week, the other will survive three-and-twenty weeks. —*Blackwood.*

**ARSENIC IN WALL PAPER.**—Dr. A. Halley has published the following important remarks on this new mode of slow poisoning in the *Times*.—"In the autumn of 1856 my study, a room some 14 feet square by 11 feet high, was papered with a newly made rich emerald green flock paper, manufactured by one of the first firms in London (Messrs. Townsend, Parker and Co.), and shortly after the room was finished I commenced to work in it regularly every evening for some five or six hours, the room being lighted with gas by a single fish-tail burner. Within a few days I began to suffer considerably in my health from constant headache, dryness of throat and tongue, with internal irritation. I could attribute this to no particular cause, as no change had taken place in my habits, and up to this period my health was excellent. Not to enter too much upon detail, suffice it to say that after some three weeks I became completely prostrated, almost losing the use of my left side, and was for some time under the care of two physicians. Not suspecting the room, as soon as I had somewhat recovered I returned to my study, and was alarmed to find that after a few days the same symptoms returned, and obliged me to desist; until at last I found that whenever I worked for any length of time in this arsenic-papered room I invariably suffered from the same set of symptoms, which did not come on if I remained in other rooms not so papered. Still, the cause was a mystery to me, as I was not aware that arsenic was used in paper-hangings, or that the paper in my room contained it, until, upon reading the *Medical Times and Gazette* for May 23, 1857, my attention was attracted to a paper by Dr. W. Hinds, of Birmingham, describing the symptoms in 'a case of arsenical poisoning by a decorative wall paper,' the details of which were remarkably similar to those that I had myself experienced and so severely suffered from. My paper was at once submitted to chemical scrutiny, and found to contain a very large quantity of arsenic in the form of arsenite of copper—nearly a drachm to the square foot. Still the question remained,—Was it the arsenic in this paper that really produced the unpleasant symptoms? The air of the room was next carefully tested (by means of sheets of paper soaked in a solution of the ammonio-nitrate of silver—a very delicate test for arsenic), and distinct crystals of arsenious acid, visible under a low power with the microscope, and sufficiently well defined and numerous to preclude the possibility of mistake, were obtained on two repeated and separate occasions. I need hardly say that after this the

paper, though a costly, new, and handsome one, was speedily stripped off the walls, and a plain wainscot oak paper substituted. I have since regularly used the room—the conditions of which in other respects remain the same—without experiencing any of the ill effects so constant before, and have now recovered my health.

"It may, perhaps, interest your readers if I state that, from experiments since conducted by means of an aspirator, with a view to ascertain the amount and law of volatilization of the arsenic, the following results, though incomplete, may be fairly relied on:—

"1. That at ordinary temperatures with common atmospheric air the amount of arsenic given off is inappreciably small, although, in opposition to Mr. Fletcher's statement, these papers do not take long to decidedly fade.

"2. That even at a somewhat higher temperature with common air the effect on these papers is not very marked.

"3. That no arsenic was detected in the gas supplied and used in the room.

"4. But that the products of the combustion of gas, passed through an 'aspirator' filled with the arsenical paper, gave distinct evidence of the imbibition of arsenic in the passage of the air through the paper, crystals of arsenious acid being obtained from it.

"5. That although from temperament, etc. the deleterious effects produced by this combination of arsenic in the paper with the products of combustion of carburetted hydrogen gas vary considerably in character and amount of intensity, still that they are very generally experienced by persons inhabiting rooms so decorated and thus exposed to the influence of these papers; and when it is considered that the experiments upon the air in the room above detailed extended over a period of only some ten hours each, and yielded distinct crystals of arsenic, it may be readily understood how a person constantly breathing—physiologically the most active means for imbibing the poison, arsenic—for several consecutive hours should suffer so severely in consequence of inhabiting a room so papered.

"My own case is so marked—the results so evidently following the cause, and so immediately ceasing on its removal,—that I feel it but right, with your permission, to add my voice of caution to the public, and to advise them to have full faith in the carefully weighed statements and opinions of Dr. Taylor."

**SEWAGE IN THE THAMES WATER.**—In a Parliamentary paper, Mr. Gurney reports that "sewage from the drains may be divided into three parts—the liquid, solid, and gaseous, or soluble, insoluble, and æriform. It is a vulgar error to suppose that the solid or insoluble sewage floats on the surface of the water, or 'floats up and down with the tide.' On the contrary, its specific gravity is as much as 1.325; it will sink one foot per minute in still water or slow currents, and precipitate (or rather deposit) in stronger currents, moving in parallel lines; at a greater rate than 170 feet per minute, it will not precipitate (or deposit), the force of convection then being greater than, and consequently overcoming, the force of gravitation. Mr. Gurney gives an interesting account of his experiments with the insoluble sewage taken from the river which were made in August, the month of least water. The quantity of sewage retained in the Thames seems to be a ruling or constant quantity; the river is never choked up, nor is it ever even clean; and the most filthy part of the stream lies between Hungerford and the Penitentiary at Millbank, this being mainly occasioned by two retrogrades, the one outside the Speaker's residence, the other at Hungerford. The liquid and soluble sewage is carried away by excess of the downcast, but some part hangs about in the cesspools. The rate of solution of solid sewage after maceration in the river has not yet been ascertained, but it is estimated that generally one-fifth will be dissolved after a week's maceration. Mr. Gurney, in fine, recommends that all the retrogrades and brattice cesspools be destroyed,—that all the obstructions to an uniform flow of the river at low water be removed; that the projections along shore be rounded off, and the hollows filled up; that the serrated edges of the river at low water be made plain, and continued along the whole line of low-water mark; that the width of the water way at the lowest ebb be not more than 140 yards from side to side, so that the river may not only run in an uniform current, but at a minimum rate of 225 feet per minute; and that from low-water mark upwards the beach be so constructed, that the shore may rise at an

angle of about three or four degrees with the horizon, or, in road-making parlance, of not less than 1 in 16, to facilitate the fall of the sewage into the bed of the river." This is all well enough; but when are we to prevent the sewage from entering the river?

## VITAL STATISTICS OF LONDON.

Week ending Saturday, January 9, 1858.

### BIRTHS.

Births of Boys, 890; Girls, 810; Total, 1700.  
Average of 10 corresponding weeks, 1847-56, 1529.

## BOOKS RECEIVED.

On Dislocations and Fractures. By J. Maclell, F.R.C.S. Fasciulus I. London: 1858.  
The Diseases of Children. By F. Churchill, M.D. Second Edition. Dublin: 1858.  
Human Histology. By E. R. Peaslee, A.M. M.D. Philadelphia: 1857.  
Sanitary Legislation and Administration in England. By H. W. Rumsey. London: 1858.  
The Origin and Objects of the New Oxford Examination for the title of Associate in Arts. By T. D. Acland, Esq. London: 1858.  
A Reply to the Charge made by the Commissioners in Lunacy against the Management of the Portland-house Lunatic Asylum. By S. Millard. London: 1857.  
Alcohol: its Place and Power. By James Miller, F.R.C.S.E. Edinburgh: 1858.  
De la Cause Immédiate et du Traitement Spécifique de la Phthisie Pulmonaire et des Maladies Tuberculeuses. Par J. Francis Churchill, D.M.P. Paris: 1858.  
A Short and Plain History of Cholera: its Causes and Prevention. Written for Popular Use. By W. E. C. Nourse, F.R.C.S. London: 1857.  
The Hygiene of the Turkish Army. By J. N. Radcliffe, M.R.C.S. London: 1858.

## TO CORRESPONDENTS.

Mr. Wright has sent us a long reply to Mr. Wilde's last letter, but as it contains much not likely to interest the great body of our readers, we need only say that Mr. Wright published full particulars of the Duke of Wellington's case, which he says may be procured from Mr. Wesley, 54, Paternoster-row.

If Dr. Silvester will send woodcuts of the diagrams illustrating his letter it shall appear immediately.

Alia.—The girl must have been recovering before the handkerchief was used.

Jacobi should say on what grounds he recommends the internal use of camphor and chloroform in poisoning by strychnia.

A Correspondent.—The summer Preliminary Examination in Classics and Mathematics at Apothecaries' Hall will take place on the third Tuesday in July. Particulars may be learned by application to the Secretary to the Court of Examiners, at the Hall, in Blackfriars.

Mr. Garner's case of Malformation shall appear in an early number.

Mr. Greenwood's notice of operations at the Westminster Hospital arrived too late for insertion last week. Such notices should be at the office before 1 p.m. on Thursdays.

Mr. Lacy.—We regret as much as any one can the delay which has occurred in the publication of Dr. Jenner's lectures; but the fault is not ours. The lectures are invariably printed immediately after they are received from Dr. Jenner.

B.—The remarks on Croup by our esteemed Correspondent are scarcely adapted to our pages. Medical men are well acquainted with the use of small doses of Ipecacuanha and stimulating liniments to the chest, but are naturally sceptical as to their powers as preventives of croup, and slow to admit that because a child for whom they have been prescribed has escaped this disease, the relation between the remedy and the escape is made out satisfactorily.

M.D.—The last new cure for hydrophobia used by Dr. Roser is probably about as useful as all former ones. As the internal remedies, *Synanchus erectum* and *Myiobris simaculata*, are preceded by cauterization of the bite, there can be little doubt that the cauterization is the really efficient part of the treatment.

A Correspondent says, "I have remarked that Jewesses, fishermen's wives, and the wives of mechanics, who scarcely pass a day without their salt herring, are extremely prolific, scarcely ever barren. Witness the wives of the mechanics at Poplar, a cold, moist, unhealthy district,—births there are in excess of those of any other place of the same size. This points to a fish diet, with iodine and iisinglass. The common domestic hen becomes a prolific layer of eggs, if kept on a fish diet."

A London Surgeon.—As Dr. Jacob has published a full apology for the attack he admitted into the Dublin Medical Press upon Mr. Coulson, Mr. Childs, and Mr. Shillitoe, on the authority of a writer "not known" to him, we can only express surprise that Dr. Jacob should have admitted week after week personal attacks from an individual "not known" to him, and one "known" by every one who reads his trash to be indebted solely to his imagination for his facts.

Oculus.—A census report gives the number of blind in France at 37,000.

### COMMUNICATIONS have been received from—

Dr. RIGBY; Professor SYME; Mr. TOYNBEE; Dr. HALFORD; Mr. HOLMES COOTE; Mr. BIRKETT; Mr. WEEDON COOKE; Mr. SMITH, Southam; The REGISTRAR-GENERAL, Edinburgh; Staff-Surgeon ROBERTS, Cairo; Dr. SYLVESTER; Mr. WRIGHT; Dr. MOORE; Mr. MACKENZIE; Mr. BARLOW; Mr. HUGHES; Mr. DALTON; Mr. LAWRENCE; Mr. GARNER; Mr. GREENWOOD; Mr. MARSDEN; Dr. BAINES; Mr. McDERMOTT; Mr. NEWMAN; Mr. WALMSLEY; Mr. PRICHARD; Mr. LACY; Dr. FRANKS; Mr. DAVIS; Mr. BAINBRIDGE; Mr. BROWN; Mr. STOKES; Mr. WATTS; Mr. HARTLEY; Mr. D. DEVENY; Dr. J. HOOVER; Mr. J. S. SYKES; Dr. J. WAY; Mr. W. H. RADLEY; Dr. McKINLAY; Mr. W. T. HUNT; Mr. J. McCREA; Mr. E. MEADE; Mr. A. L. BOGLE; Dr. MILLER; Dr. ASHTON; Dr. DAY; B. C.; Mr. CRUMMEY; Mr. COLLINS.

## APPOINTMENTS FOR THE WEEK.

Jan. 16, Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's, 2 p.m. Charing Cross, 1 p.m.  
MEDICAL SOCIETY OF LONDON, 8 p.m. Dr. Semple, "On the Inflammatory Diseases of the Respiratory Organs."

18. Monday.

Operations at the Royal Free Hospital, 1 p.m.; Metropolitan Free Hospital, 2 p.m.; Orthopaedic Hospital, 3 p.m.

19. Tuesday.

Operations at Guy's, 1 p.m. Westminster, 2 p.m.  
PATHOLOGICAL SOCIETY, 8 p.m.  
ROYAL INSTITUTION, 3 p.m.: Professor Huxley, "On Vital Phenomena."

20. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m.; Orthopaedic Hospital, 3 p.m.  
GEOLOGICAL SOCIETY, 8 p.m.

21. Thursday.

Operations at St. George's, 1 p.m.; Middlesex, 12½ p.m.; Central London Ophthalmic, 1 p.m.; London, 1½ p.m.  
ROYAL SOCIETY, 8½ p.m.  
ROYAL INSTITUTION, 3 p.m. Professor Tyndall, "On Heat."  
LINNEAN SOCIETY, 8 p.m.  
HARVEIAN SOCIETY. H. C. Stewart, "On the Epidemic Diarrhoea of the Past Season."

CHEMICAL SOCIETY, 8 p.m.  
GROSVENOR PLACE SCHOOL MEDICAL SOCIETY, 7½ p.m.  
MIDDLESEX HOSPITAL MEDICAL SOCIETY, 8 p.m. Mr. Eaton, "On some Diseases of the more important Structures of the Eye."

22. Friday.

Operations at the Moorfields Ophthalmic, 10 a.m.; Westminster Ophthalmic, 1½ p.m.; Great Northern, 2½ p.m.  
ROYAL INSTITUTION, 8½ p.m. Professor Tyndall, "On some Physical Properties of Ice."

## EXPECTED OPERATIONS.

At the Westminster Hospital, next Tuesday, Mr. Barnard Holt has two strictures cases for forcible dilatation.

King's College Hospital.—The following operations are expected at this hospital to-day (Saturday), at 2 o'clock:—

Lithotomy; examination of wrist; operation for ununited fracture; division of cicatrix following burn, by Mr. Fergusson.

## Great Saving in the Purchase of Six

GROSS of NEW MEDICAL GLASS BOTTLES and PHIALS assorted to suit the convenience of Purchasers, at ISAACS & SON, Medical Glass Bottle Manufacturers.—London Warehouse, 6, Warren-street, Tottenham-court-road.

	s.	d.
6 and 8 oz., any shape, plain, or graduated ..	8	0 per gross.
3 and 4 oz., ditto ..	7	6 do.
1 oz. Moulded Phials ..	4	6 do.
1 oz. ditto ..	5	6 do.
1½ oz. ditto ..	6	0 do.
2 oz. ditto ..	7	0 do.

No remittance required until the goods are received. Packages free. Delivered free within seven miles. Immediate attention to country orders. Post-office Orders payable to S. Isaacs and Son, at the Post-office, Tottenham-court-road, London. Bankers: Unity Bank.

## Recent Improvement by Mr. Jeffreys

in the RESPIRATOR. J. E. PERCIVAL respectfully invites the attention of the Profession to an important improvement in the Oral Respirator, which, having a maximum warming power of no less than 40°, can be instantaneously reduced, even without being displaced, to any of five grades down to a minimum of about 15°, and vice versa. So that, in an atmosphere varying between 30° and 55°, air may be respired of one steady temperature of about 70°, or lower if desired.

The Profession are doubtless aware that the name Respirator is being assumed for various defective imitations. The RESPIRATOR may be had of the principal Chemists and Surgical Instrument Makers in town and country. Wholesale Office, 25, Bucklersbury, City. J. E. Percival, Manager.

## Great Reduction in the Prices of New

MEDICAL GLASS BOTTLES and PHIALS, at the ISLINGTON GLASS BOTTLE WORKS, ISLINGTON-PLACE, PARK-ROAD. Warehouse—2, UPPER COPENHAGEN-STREET, BARNESBURY-ROAD, ISLINGTON, LONDON. N.

E. and H. HARRIS beg to submit the following prices for quantities of not less than 6 gross, assorted to suit the convenience of the purchaser.

	s.	d.
6 & 8 oz., any shape, plain or graduated ..	8s.	per gross.
3 & 4 oz., do. ..	7s. 6d.	do.
1 oz. white moulded phials ..	4s. 6d.	do.
1 oz. do. ..	5s. 6d.	do.
1½ oz. do. ..	6s.	do.
2 oz. do. ..	7s.	do.

No remittance required until the goods are received. Packages free. Delivered free within 7 miles. Immediate attention to country orders. Post-office orders, made payable to E. and H. HARRIS, at the Chief Office, London.

Bankers: Union Bank of London.

## Williams and Son's Pure Glycerine

SOAP. Analysed by Dr. Hofmann, F.R.S., and Professor Redwood, Ph.D., strongly recommended by many eminent members of the Medical Profession, and favourably noticed by the following Medical Journals:—

THE LANCET.  
THE MEDICAL TIMES AND GAZETTE.  
THE BRITISH MEDICAL JOURNAL.  
THE MEDICAL CIRCULAR.  
EDINBURGH MEDICAL JOURNAL.  
THE DUBLIN HOSPITAL GAZETTE.

It is suited to all cases of delicate skin (whether arising from disease or otherwise), and is admirably adapted for nursery use. May be had of all respectable Chemists, Perfumers, etc.

SOAP-WORKS, CLERKENWELL, LONDON, E.C.

## PURE SPIRITS FOR THE FACULTY.

S. V. R. 56 O.P., 17s. 6d. net Cash.

This quotation admits of neither credit nor discount, and 1s. per gallon must be added for packages, to be allowed on their return.

HENRY BRETT and CO., Old Fumival's Distillery, Holborn.

## The Medicated Cod Liver Oils,

comprising  
OLEUM MORRHUE CUM QUINA.  
OLEUM MORRHUE CUM FERRI IODIDO.  
&c. &c. &c.

Prepared only by SAVORY and MOORE, 143, New Bond-street.

## Liquor Pepsinæ.—A Convenient and

efficacious preparation by  
SAVORY and MOORE, 143, New Bond-street.

## Wines from Cape of Good Hope.—

PORT, SHERRY, MARSALA, MADEIRA, BUCCELLAS, &c., all at 20s. per Dozen—pure and wholesome Wines, free from acidity and brandy, the produce of vineyards at the Cape of Good Hope, where the vines of Portugal and Spain are now being carefully cultivated, and have escaped the disease. Her Majesty's Government allows these Wines to be imported at half the duty, hence the low price of 20s. per dozen. Samples of any two qualities sent on receipt of twelve stamps.

"That wine, equal to any ever produced, can be made at the Cape, all the world has acknowledged."—Times, Nov. 8th, 1856.

THE UNIVERSAL BRANDY, 15s. per Gallon, or 30s. per dozen.  
W. and A. GILBEY, Wine Importers, Brandy Distillers, &c., 372, Oxford-street, London, W. Cheques to be crossed to our Bankers, the Bank of England.

## Kamala, a Powder obtained from the

Capsules of Rottlera Tinctoria. Recommended as a remedy for Tape-worm; medium dose, two drachms; see Medical Times and Gazette, May 2, and December 19, 1857.

ALLEN and HANBURY have a supply of the above-named Medicine, price to Members of the Profession, 1s. per ounce; if by post, 1s. 4d. Tincture of Kamala, dose two to three drachms, price 1s. per ounce.

London: Plough-court, Lombard-street, E. C.

## Pepsine.—M. Boudault begs to state

that he cannot be answerable for the purity and strength of any Preparation sold under his name unless obtained from his sole Agent, Mr. PETER SQUIRE, her Majesty's Chemist, 277, Oxford-street, London, to whom all applications respecting it must be addressed.

Second Edition of Boudault on "Pepsine," with Remarks by English Physicians Edited by W. S. SQUIRE, Ph.D., published by J. Churchill, London, may be also had of the Author, 277, Oxford-street, price Sixpence.

## Broughams.—Kinder, M'Naught, and

SMITH, MANUFACTURERS, WORCESTER, beg respectfully to invite the attention of professional men to their improved Medical Broughams, as under:—

Width of Seat.	Weight.	Price.
3 ft. 5 in. ..	7½ cwt. ..	85 Guineas.
3 ft. 6 in. ..	8½ cwt. ..	95 Guineas.
3 ft. 7 in. ..	9 cwt. ..	100 Guineas.

The latter, including a segmental front, with seat for third person.

These Carriages are constructed, by the aid of machinery, of the best material, are of excellent workmanship, and particularly adapted to the wants of medical men, either in town or country. Drawings and other particulars forwarded on application.

## Poultices superseded by the use of

MARKWICK'S PATENT SPONGIO PILINE.

As a substitute for common poultices and fomentations, the superiority of this article is unquestionable. It is strongly recommended by the most eminent of the Faculty for its cleanliness, economy, lightness, and general efficacy, and is now used in several of the hospitals. Also, Markwick's Patent Piline, for Cholera Belts, Rheumatism, Chest Protectors, Respirators, Lumago, etc.

Sold, retail, by Chemists and Druggists, and wholesale only by  
GEORGE TRIMBEY, 41, Queen-street, Cheapside.

## A New Discovery. -- Mr. Howard,

SURGEON-DENTIST, 52, FLEET-STREET, has introduced an entirely NEW DESCRIPTION OF ARTIFICIAL TEETH, fixed without springs, Wires, or Ligatures. They so perfectly resemble the newest teeth as not to be distinguished from the original by the closest observer; they will NEVER CHANGE COLOUR or DECAY, and will be found very superior to any teeth ever before used. This method does not require the extraction of roots, or any painful operation, and will give support to and preserve teeth that are loose, and is guaranteed to restore articulation and mastication; and that Mr. Howard's improvements may be within the reach of the most economical, he has fixed his charges at the lowest scale possible. Decayed Teeth rendered sound and useful in mastication.

## For Infants.—The British Feeding

BOTTLE (registered) may be placed in any position without the Food running out. The supply can be regulated by a stop-cock: being electroplated, it may be instantaneously cleaned. Unlike wood, ivory, or bone, it is impervious to moisture, cannot crack or become sour; there is no possibility of the infant drawing air with the food.

By W. T. COOPER, Pharmaceutical Chemist, 26, Oxford-street, London. Price 7s. 6d., or free to any Railway Station, 8s. 6d.

## The Artificial Tympanum for the

Relief of Deafness, attended by loss or Injury of the Membrana Tympani, and for the Cure of Discharges from the Ear. The Invention of JAMES YEARSLEY, Esq., M.R.C.S. Eng., Surgeon to the Metropolitan Ear Infirmary, Sackville-street, etc. etc.

Superintendent of the Patent, Mr. CHARLES GREENE, to whom all communications should be addressed. Depot, *pro tempore*, 20, King William-street, Strand.

PRICE—Silver Tube and a Month's Supply of Prepared Cottons, with Printed Directions, 2s. 6d.; sent by post, 2s. 8d. Prepared Cottons without the Silver Tube, 1s.; by post, 1s. 2d.

This invention has been Patented, not with a view to Profit, but to insure the transmission of Printed Directions with each Apparatus, for the guidance of the patient; and secondly, to prevent further piracy by the substitution of improper materials, which by constant failure, bring the principle of treatment involved in the invention into disrepute.

## Crosse and Blackwell, Purveyors in

Ordinary to Her Majesty, respectfully invite attention to their PICKLES, Sauces, Tart Fruits, and other table delicacies, the whole of which are prepared with the most scrupulous attention to wholesomeness and purity. The practice of colouring pickles and tart-fruits by artificial means has been discontinued, and the whole of their manufactures are so prepared that they are not allowed to come in contact with any deleterious ingredient. A few of the articles most highly recommended are, Pickles and Tart Fruits of every description, Royal Table Sauce, Essence of Shrimps, Soho Sauce, Essence of Anchovies, Jams, Jellies, Orange Marmalade, Anchovy and Bloaters Pastes, Strasbourg and other Potted Meats, and Cal's Foot Jellies of various kinds for table use. C and B. are also sole agents for M. Soyer's Sauces, Relish, and Aromatic Mustard; and for Carstairs' Sir Robert Peel's Sauce, and Payne's Royal Osborne Sauce. The above may be obtained of most respectable Sauce Vendors throughout the United Kingdom; and Wholesale of

CROSS and BLACKWELL, 21, Soho-square.

## ORIGINAL LECTURES.

## LECTURE

ON

## THE RADICAL CURE

OF

## REDUCIBLE INGUINAL HERNIA.

DELIVERED AT THE

Grosvenor-Place School of Medicine.

MONDAY, JAN. 11, 1858.

By T. SPENCER WELLS, F.R.C.S.

Lecturer on Surgery at the School; Surgeon to the Samaritan Hospital, etc.

GENTLEMEN,—As I am about to perform before you an operation for the radical cure of reducible inguinal hernia, I avail myself of the opportunity of advocating a method of treatment which, as it is proved by very ample experience to be both safe and successful, is worthy of general adoption in the treatment of one of the most common and most fatal diseases to which the human race is subject.

You have probably seen in the *Medical Times and Gazette*, during the last year or two, reports of several cases in which what is called WUTZER'S OPERATION has been performed. This is the operation, with an instrument modified in some essential particulars upon that of Wutzer, I am about to demonstrate before you; and it is with very great satisfaction that I do so, as I was the first Surgeon to perform this operation in Great Britain, and the first who brought it before the notice of the Profession here. I did so in a paper which was read before the Royal Medical and Chirurgical Society on the 9th May, 1854, and was published in the 37th volume of the "*Medico-Chirurgical Transactions*." I had assisted Dr. Burmester to do the operation in Malta in 1847. I did it myself in Malta in 1848, and in England in 1850, after a visit I had paid to Wutzer in Bonn, when I saw some of his cases and procured his instruments. Between May, 1854, and February, 1855, I did four other cases in England. I then went to the East, and Mr. Stretton, one of the Surgeons in my division of the Hospital at Renkioi, did it upon a Greek. Mr. Holmes Coote was there at the time, and saw this case. He was so pleased with the result, that on his return to England he performed the operation at St. Bartholomew's Hospital, and thereby deserves the credit of introducing it into London Hospital practice. This was more than two years after my paper had been read at the Medico-Chirurgical Society—a curious example of the slow progress practical improvements make in our large Hospitals. Then Mr. Jones, of Jersey, took up the operation, and as he asked me to get the instruments made for him by Mr. Coxeter, I directed Mr. Coxeter to have the needle silvered, to obviate the rusting, which I had found objectionable. I think Dr. Vaudin, of Jersey, and Mr. Hutchinson were the next to take up the practice, and then Mr. Erichsen. More recently Mr. Cumming, of Exeter, has done it. I have had three more cases since my return from the East, and these are all the cases I have heard of in this country. If you add Dr. Burmester's, Mr. Stretton's, and my own case done abroad, to the eight of my own, seven of Mr. Jones's, three of Dr. Vaudin's, three of Mr. Coote's, two of Mr. Hutchinson's, four of Mr. Erichsen's, and one of Mr. Cumming's, done in England, you will find that thirty-one of these operations have been performed by British Surgeons, and there has not been a death or dangerous symptom in any one case. But, more than this, the operation has been almost uniformly successful. I do not lay great stress on the cases operated on within the last year, although they assist in proving the safety of the operation, as they are still open to the possibility of relapse; but some of my own cases have now passed, ten, nine, seven, and three years, without a sign of return. I have not had a failure, a relapse, or a bad symptom, in any one of the nine cases. Mr. Jones tells me the same thing. He says he has not seen anything to give him the slightest fear or anxiety after the operation; and its success has been complete. He did it in one person as old as 63.

Vol. XXXVII. No. 956.—NEW SERIES, No. 395.

He told me of one man whom he saw drunk in a wine-shop in Jersey a few weeks after the operation, wearing no truss, and jumping on and off the counter to show how well he had been cured. Mr. Coote's three cases were all successful, but he tells me that in another case "a man was persuaded against his will to undergo the operation. The needle was too thin, and it bent, and missed the border of the ring, consequently the plug of integument slipped out. The patient had no bad symptom, but refused to have the operation completed." Mr. Erichsen informs me that of his four cases three succeeded, but "in the fourth it failed in consequence of the patient, a lad, walking about the ward while the instrument was still applied." One of Mr. Hutchinson's cases succeeded; in the other he tells me the man had a very large hernia, and suffered from violent cough. Symptoms of inflammation of the sac—not peritonitis—came on, which induced him to remove the instrument on the fourth day. The man did well, but the hernia was not radically cured.

A case related to me by Dr. Vaudin, of Jersey, tested the value of the operation most completely. A man, 30 years of age, the subject of phthisis, had had a large oblique inguinal hernia for seven years. The operation was performed on the 6th of Oct. last. The man died about the 1st of January, but notwithstanding the severe coughing there was no descent of the hernia. Unfortunately a post-mortem was not permitted. Dr. Vaudin adds, "I have not heard one of the patients operated on complain of pain or discomfort caused by the operation." In another of his cases, the operation was severely tested by a two-months' pedestrian tour, but no relapse has occurred. Two of Mr. Jones's patients were seamen, who are now following their occupation without wearing trusses. Some of my own patients are men of very active habits, and I have not yet seen a sign of recurrence of protrusion.

I think I may say, therefore, that the experience of British Surgeons, so far as it has gone, speaks strongly in favour of the operation, and if we look to the continent we find a much larger store of recorded experience. Wutzer, in a letter to me, in 1853, says, "I am not able at present to give you the statistical results of all the cases upon which I have operated, as I have not time to collate them. I can now only say that, since the autumn of 1838, I have repeatedly practised my operation in the clinique every session before many witnesses, and that I have never seen severe peritonitis follow it, still less any fatal result. All those operated on have not been cured. In several, relapse followed, but this was traceable either to the patient leaving off the truss too soon, or undertaking very hard bodily labour soon after the operation." Professor Sigmund, of Vienna, informed me that he had performed the operation nineteen times in the great Hospital of that city, with complete success in fifteen cases. No death happened, but in two cases there was some gangrene of the integuments, and in two relapse occurred.

Last autumn I was in Munich, and I called on Professor Rothmund, who has a larger experience of the operation than any other Surgeon. I saw him perform the operation in one case, and saw two men upon whom he had operated, on one three days, and on the other ten days before. I had a long conversation both with the Professor and his assistants. They said the increasing number of patients coming for operation was the best proof of its safety and success. At first Rothmund found it difficult to induce ten patients to submit to it in a year. Now they apply every day. They are mostly working men; and one tells the other how he has been cured. On inquiry as to relapse the answer confirmed my previous impressions, namely, that in cases where the canal is not larger than to admit the finger easily, the radical cure may be relied on with almost absolute certainty, and that the probability of relapse increases with the size of the canal and rings. When the rings are very large and the canal very short, the chief use of the operation is to make a truss effective. In these cases of widely dilated rings and short canal my impression was that the operation might be hazardous, but the experience at Munich shows that this fear is unfounded, provided very large cylinders be used, so that the rings are well filled and descent of intestine by the side of the cylinder is impossible. Rothmund has done the operation about 400 times in the Clinical Hospital at Munich, and he told me that he had done it much more frequently in private practice, so that he felt convinced he must have operated a thousand times, and without one fatal result. This, I think, is more than almost

any one could say of the most trifling operation. No one could expect to do a thousand operations for hare-lip—to tie a thousand navels or piles—to remove a thousand small tumours—in fact, do the most trivial surgical operation a thousand times, without some untoward result following, accidentally, in some one case. So that this evidence is very strong indeed in favour of the almost perfect safety of the proceeding.

You see I am anticipating objections already; I do so because there is still so strong and general a feeling among Surgeons against the adoption of any operative proceeding whatever for the radical cure of hernia, that I feel it necessary at the very outset to convince you that I am not advocating some novel and dangerous innovation, of the safety and propriety of which I am not fully assured. I have really proceeded with great caution—I may say too great caution—in this matter, under the influence of the general prejudice against any operation of this kind. I was very careful indeed—too careful I think now—in the selection of cases. I waited two years after my first case before I found a second patient—four years after my second before I found a third—willing to have the operation done upon the very qualified manner in which I advised it. I did not venture to urge the operation upon patients. It was only when warmly requested to do it that I consented; and when I read the paper in 1854, I did not advocate it very strongly, but simply asked the members of the Society “to consider how far the evidence I have adduced of its safety and success should lead to its further adoption in this country.” With further experience, however, and especially since my visit to Munich, I feel much more confident, and take every opportunity, in suitable cases, of recommending patients to submit to the operation, and of bringing it before you and the Profession generally.

Before showing you the instrument of Wutzer, and the modified instrument of Rothmund which I now use, it will be well to make you acquainted with the principles of the operation. There are two ways by which the radical cure of reducible hernia can be effected. The sac may be destroyed or closed, or the sac and hernial apertures may be filled up. A great variety of proceedings, with the first object in view, have been adopted from very early periods in the history of surgery down to the present time. Celsus advised incision of the integuments and sac, so as to lay open the sac, and allow it to heal by granulation. This practice was followed so lately as by Pott and Abernethy, but the most dangerous results followed. Then castration was performed in the hope of closing the sac, and it was carried to such an extent in France that it was made penal by statute. This led to what was called the “Royal Stitch,” because by leaving the testes uninjured, it “gave subjects to the king.” This operation consisted in laying bare the sac, excising a portion of it, and bringing the upper remaining portions together by suture. Then the sac has been destroyed by caustics or the actual cautery. It has been tied close to the ring, after exposure, by incising the integuments. It has been tied subcutaneously by passing pins beneath it. The adhesion of the opposed surfaces of the sac, and consequent obliteration of the cavity, have been attempted by subcutaneous scarification, by acupuncture, and by the injection of iodine. This injection of iodine is alluded to by Mr. Fergusson in his last edition, as a plan followed in America by some charlatans who attempt the radical cure of hernia by a secret method. Mr. Fergusson seems to think well of it, though it proved very unsuccessful in the practice of its originator, Velpeau. Indeed any attempt merely to obliterate the sac, putting aside its great danger, is bad in principle, because the mere obliterated sac offers very little impediment to a new hernial protrusion. We must do more than this. We must contract or close the passage through which protrusion takes place. Now all attempts to do this, with the single exception of compression, have been exploded as dangerous or useless. Compression by a truss and well-fitted pad, properly applied, frequently leads to the radical cure of hernia in young persons, by exciting exudation and adhesion. In adults, however, a radical cure is so seldom effected in this way that we all look upon compression after the age of puberty as a simple safeguard against the descent of the hernia, very seldom attempting to produce a radical cure by a truss; and when the attempt is made, it leads in the great majority of cases to disappointment. The principle of the second plan is closure of the hernial canal by a portion of skin, forming a sort of plug pushed into the canal, and

made to adhere in its new situation. In other words, the inguinal canal must be closed by a portion of the scrotum pushed into it, and fixed there. It can only be fixed there securely by adhesive inflammation of the serous coat of the sac occupying the canal, and it is necessary for the safety of the patient that the inflammation so excited should not extend to the peritonæum lining the abdominal cavity.

Now look at these diagrams of the parts implicated in such an operation. In that to the left you see the sac and abdomen empty; the peritonæum and its prolongation forming the lining membrane of the canal or sac are of course continuous. Now see the effect of pushing a portion of scrotum into the sac as I do now, and as you see represented in the diagram to the right. Gerdy supposed that the sac remained behind the inva-

ginated portion of skin, or was pushed before it, and that the plug might be fixed without piercing the sac. I am convinced that this does not hold good as a general rule. Even in very recent cases the serous layer of the hernial sac is so firmly adherent to the walls of the inguinal canal, that it can only be separated from it by dissection. This, I believe, is what commonly happens—the sac is folded upon itself before the invaginated portion of scrotum; and if this portion be fixed by the passage of a needle, or needle and thread, that needle and thread transfix the sac. This wound of the sac we must consider fairly, and not shut our eyes to it.

I do not wish to assert that the sac can *never* be pushed before the invaginated scrotum. On the contrary, you may meet with cases where the patient has not worn a truss, in which the sac can be pushed completely into the abdomen. In other cases of old hernia, where the sac has been thickened and the surrounding cellular tissue is very loose, the same thing may happen, the sac hanging into the abdomen from the internal ring like an empty purse.

I will now show you Gerdy's operation on this subject. The invagination of the skin of the scrotum is the first stage of this operation, as it is in that of Wutzer, but Gerdy merely fastened the plug in its new position by a suture. You see I now form the plug, push the needle along my finger, through the canal and integuments, fasten the thread, withdraw the needle, then make a second puncture, cut off the thread, and remove the needle. I could do the same thing easily with two needles, one at each end of the thread. In either case this diagram shows you the result, and I feel convinced that it represents what really happens in most cases, and I suspect Wutzer is right when he says that the puncture of the sac is almost necessary to secure firm adhesion. The result of this suture is just what you would expect—union of the opposed surfaces of the sac at one point. This slight union would appear likely to give way before very slight force, and this proved to be the case, for relapses were extremely common after operations performed in this manner. A more perfect closure of the canal than can be obtained by Gerdy's operation being evidently desirable, various plans were devised for effecting this closure. One of the simplest is that of Schuh, of Vienna, who used the thread of Gerdy for drawing up and holding in the inguinal canal, as I now show you,

a sort of wick of cotton of sufficient size to fill the canal. The pressure of this, however, is not sufficiently firm or uniform. Here is an instrument contrived by Leroy d'Etiolles.

It is a metallic cylinder and a cover, which can be so screwed together as to press the invaginated scrotum and abdominal parietes together. If this could be fastened tight enough to prevent its slipping out without injuring the compressed skin it might be a useful instrument, but it cannot. Here is another, something like the common American clothes-peg.

It was contrived by Max Langenbeck, and has been used by him with success, but it was purposely left so long applied that sloughing of the compressed parts followed, and it was to the subsequent granulation that Langenbeck looked for closure of the ring. The process requires long confinement to bed, so that you see we want some much milder process than that. This Wutzer has afforded us. Here is his instrument, made by his own maker in Bonn, the one I used in my early operations. In this diagram the entire instrument is shown below, while above there is a second view of the needle which passes through its centre when withdrawn.

The cylinder, which is intended to take the place of the index finger after it has pushed a plug of scrotum through the ring into the canal, is made of very hard wood of different lengths and diameters according to the condition of the canal in each case. In its centre is a canal through which an elastic steel needle passes, and comes out on the upper surface near the point. Over this a concave cover, also of hard wood, is made rather wider than the cylinder, with an opening to admit the point of the needle, and another opening for a metallic staff which rises from the cylinder near the handle, on which a screw works, by which the cylinder and cover can be screwed together. The handle of the needle can be removed by unscrewing.

After using these instruments of Wutzer's I soon found certain alterations desirable. The needle got rusty, caused undue irritation at the point of puncture, and became unfit for use again. This was soon obviated by electro-plating it. Then the necessity for varying the size of the cylinder in each case was troublesome and expensive. I obviated this, though imperfectly, by rolling strips of adhesive plaister round the cylinder until I made it as large as I desired. But this led to irregular pressure, and in Mr. Stretton's case caused a little sloughing, which though it did no harm might as well have been avoided. The cylinder, too, was too round for the normal shape of the canal. The point of the needle

had to be guarded by a piece of cork, which would per-  
versely be knocked off sometimes, and, worse than all, there was nothing to prevent the needle itself from slipping back—the only thing keeping cylinder and cover in their place. I had thought of different plans for correcting these faults, but not of anything so good as those for which we are indebted to Professor Rothmund. Here is his instrument. It is made, as you see, precisely on the same principle as that of Wutzer, and at first sight resembles it exactly in appearance, but the cylinder is oval, not round; the needle is not steel but silver, with a moveable steel point, and there is a knob which can be screwed on after the point is removed, and at the handle there is a spring which is an effectual safeguard against the needle slipping from its place. Lastly, in order to admit of the same cylinder serving for the occlusion of canals of various dimensions it is so made that side-pieces of different sizes can be fitted on to the central portion of the cylinder. I have here covers of different sizes, and you see that by altering the side pieces I can make the cylinder quite as large as one needle could fix well. In cases of very large rings and canals it is necessary to have the central piece perforated for two, or even three needles, but I shall use to-day this one with the single needle, as that which you would employ in the great majority of cases.

Now see what power this instrument gives us. We can alter the dimensions of the cylinder so that while perfectly filling the canal it may push the plug of the invaginated scrotum before it well up to the internal ring, and even project some little distance into the abdomen. We can fix the plug much more securely and evenly than by a suture, or either of the other compressing instruments, and we have complete command over the degree of pressure exercised.

Now for the manner of using the instrument. I need hardly say that the patient's bowels should be opened a day or two before the operation, and the rectum cleared the same day by an enema of warm water; the bladder is emptied, and of course the hernia returned if it be down. This being done you place the patient on his back, with the shoulders raised, the thighs semi-flexed, and the knees separated, just as if you are about to reduce a hernia by the taxis. You place yourself, as I do now, on the side you are about to operate on.

If you can use right and left hand equally well, you may use the left forefinger for invaginating on the left side, and the right to hold the instrument—the reverse for the right side. But the left finger will do for invaginating on either side very well. You see I operate on the left side—so I stand on the left side of the patient. I place my left forefinger here on the scrotum, about an inch below the external ring, and then push a fold of the scrotum before my finger with a little rotatory movement slowly and steadily into the canal, keeping the palmar surface of the finger turned forwards and a little outwards, until it is well under the tendon of the external oblique, and the plug of scrotum is well pressed up to, or through, the internal ring. If you place one forefinger on the abdomen, just over the internal ring, while the other is in the canal beneath the tendon of the external oblique, you will feel the tendon very distinctly. As you move the finger backwards and forwards it rolls over the tendon. You should accustom yourselves to feel this, because it is the test by which you know and can be certain that you are well in the canal, and when you have introduced the cylinder that it is in the canal, and has not slipped anterior to it. When you are quite sure that your finger is in the canal, the next thing is to get the cylinder into the place of the finger, and then to fix it there by the needle. To do this you take the cylinder with the needle passed within it as far as you can without permitting the point to project, and hold it as I do now in the right hand with the thumb before the screw, the forefinger and second finger on either side of the prong which supports the cover, and the ring and little finger on the under side of the cylinder. Then bend the left forefinger a little, draw it forwards, and slip the cylinder along its dorsal aspect at the same time as the finger itself is being withdrawn. This is the most important step of the whole operation, and the only step which is at all difficult. Without care the plug may follow the finger. Without care the cylinder, instead of slipping beneath the tendon of the external oblique, may slip between it and the integument. You must be very careful that this does not occur, by feeling, as you felt when your finger was in the canal, that the tendon rolls over the cylinder. If you do not feel this, and if the cylinder moves freely beneath the integument, you

may be quite sure it is not in the canal, and you must begin again. I wish particularly to guard you against this mistake, because I know it has been made at least once, and I suspect oftener. If you feel the tendon rolling over the cylinder you may be quite sure it is in the canal, and the end well up to the internal ring. To fix it there I have only to push on the needle till its point appears through the abdominal parietes, then to put on the cover, and use the horizontal and perpendicular screws until the cover and cylinder are evenly pressed together. Then the point of the needle is unscrewed, the knob put on, the handle of the needle removed, and all is done. You leave the patient with the instrument secured thus,

The whole affair does not take a minute, and as the only part of it at all painful is the simple puncture of the needle, it is quite unnecessary to give chloroform.

This diagram shows what I believe to be the real action of the instrument. Here you see how plug, sac, and integument are fixed and pressed together. In some few cases the sac may be pushed up before the cylinder, in some only a very small portion may be below the needle, and in others it may extend throughout the whole line of compression. If the cylinder fill the canal well the pressure is quite sufficient to cause adhesion behind as well as before the cylinder. Some to insure this have kept up pressure on the cylinder by a compress and bandage; but this is unnecessary, and even injurious, as it leads to inflammation of the spermatic chord.

I should have told you that you should oil the cylinder before using it, or else smear it as Rothmund does with cantharides ointment. Wutzer does not think it at all necessary to remove the epidermis of the invaginated scrotum. He looks upon the adhesion of the sac as the really important part of the operation. Rothmund, however, thinks additional security is obtained by removing the epidermis, and thus procuring adhesion of the opposed surfaces of the plug. He thinks also the irritation of the skin set up by the cantharides hastens the adhesive process in the sac, so that the instrument may be removed as soon as the fifth day, instead of leaving it to the seventh or eighth. He speaks from such very large experience that I feel inclined to follow his practice for the future, although I am sure it is not at all necessary to success.

Then as to the degree of pressure you apply with the screw

upon the cover—it should be very slight the first day to allow for a little swelling. The next day the screw may be tightened or loosened according to the state of the skin. The patient should be kept in bed lying on his back, with the knees raised by a pillow, and the scrotum supported by a cushion or folded towel or two put between the legs. Every day the cover should be raised, to see whether the pressure is equal and not too great. If it does not press evenly a little cotton wool may be inserted, or if it press too much at any point this may be raised by a little cotton put near it.

About the fourth or fifth day you see a little inflammatory redness and swelling round the needle puncture and commencing suppuration. On the sixth or seventh some serous fluid begins to escape round the end of the cylinder. This shows that the epidermis is separating. There is more purulent discharge from the puncture, and the instrument may then be taken away by withdrawing the needle, and carefully removing the cylinder. You will find that the skin of the scrotum may be pulled tolerably hard without yielding at all, showing that pretty firm adhesion has taken place. If it appear to yield on pulling slightly it would be well to replace the instrument for two or three days longer.

The after treatment will vary a little, according to your desire to produce adhesion of the opposed surfaces of the plug to each other or not. Wutzer filled the cavity left by the withdrawal of the cylinder with charpie, dressed the puncture simply, and then put on a common bandage. Rothmund endeavours to obliterate the cavity. He keeps the patient in bed, raises the scrotum by a suspensory bandage, keeps off the pressure of the bed-clothes by a cradle, applies simple dressing to the puncture, and over this a graduated compress which is made to exert some pressure and keep the two sides of the cavity together by a common figure of eight bandage. The bandage is changed as often as it becomes dirtied by the secretion, and is carefully reapplied. It requires from twelve to fifteen days to secure obliteration of the cavity and cicatrization of the puncture. As I said before, it is only Rothmund's great experience which would lead me to think much of the importance of this obliteration. I tried it in my second case, but no union took place, and in cases where union has taken place the condition of parts a few months after the operation has been precisely similar to those in which Wutzer's practice was followed. Perhaps a middle course will eventually be followed, not filling the cavity with charpie, nor keeping the patient to the bed or sofa after cicatrization of the puncture, but keeping him quiet until this cicatrization is firm, and leaving the cavity to close if it will under the pressure of a compress and bandage, but not being sufficiently anxious about it to prolong the confinement of the patient. In either case the inguinal canal is filled by a firm plug, and for some weeks a sort of puckered depression is seen at its mouth, but this disappears after a few months, although the plug may still be felt. After five or six years the plug itself can scarcely be felt, and the most careful examination can hardly detect anything abnormal. Rothmund convinced himself that this could not be explained by the sinking of the invaginated scrotal plug to its former position, by tattooing round the opening of the cavity, and observing that the marks did not change their position as they would have done had the plug descended.

If the pressure has been unequal, or the instrument left a day or two too long, there may be a little sloughing around the needle; but I have never seen a slough larger than a sixpence, and this only once. The only ill effect of it is some delay in the cicatrization. I believe if there is ever more sloughing than this, it must be from carelessness of the Surgeon, or some unfortunate constitutional condition of the patient, or the crowding and defective ventilation of some Hospital ward.

Allowing six or seven days for the period the instrument is applied, and from seven to fourteen days more till cicatrization is complete, you should generally prepare a patient to expect a confinement of three weeks to his room. After this he must wear for two or three months a very elastic truss, with a weak spring and large well-stuffed pad. If the pressure is too great, or the pad too small, absorption of the plug may take place, and relapse of the hernia follow. If no truss be worn, the adhesions, which are still soft and yielding, might give way. It is also well to have a suspensory bandage worn as long as the truss, that the weight of the testicles may not drag down the skin of the scrotum to its former position.

You should also forbid violent exercise until the truss can be left off. After three months the truss may be left off, and I believe the patient is fully as secure against the occurrence of hernia on the side operated on as on the other side, perhaps more so; in other words, that he has not only been cured radically of his hernia, but he has been protected against its occurrence—he is less likely to become subject to hernia on that side than a healthy man.

We are still in want of knowledge of the precise anatomical conditions resulting from this operation which post-mortem examination alone can afford. One of my patients died of phthisis while I was abroad, so that the opportunity was lost in that case. Rothmund has never in all his cases had one fatal result, although he had several when he operated by the methods of Gerdy, Bonnet, and Belmas, nor has he happened to be able to open one of his patients who have died of some other disease; but Dr. Thormann, of Chur, opened a patient of Rothmund's, who died a *short time*—the precise time is not given—after the operation, of some other affection, and he has described the appearances. The patient, 20 years old, of middle size, suffered from a reducible oblique inguinal hernia, of the size of a hen's egg, on the left side. The canal and rings were small, and the smallest cylinder was used. The radical cure was effected; and when the patient died of some other disease, Dr. Thormann found, after death, the invaginated scrotal plug so firmly united by adhesive inflammation to all parts of the canal, that it could not be separated without dissection. The external ring and the whole canal, to within six lines of the internal ring, were completely filled and closed up by the adhesion of the plug. This is the only account of a post-mortem examination after Wutzer's operation that I have been able to find.

In conclusion, let me offer some reply to objections you may hear raised to the operation.

*Firstly.* The danger and inutility of other operations is no objection to this. We do not incise or excise the sac—we do not destroy it by caustic or the hot iron—we do not tie it—we do not scarify it—we do not inject it with iodine, or do any one of the foolish things which experience teaches us to lay aside. We perform a simple operation, which experience teaches us to be both safe and efficacious.

*Secondly.* Don't be frightened by those who shake their heads at every new thing. When I brought over the ophthalmoscope from Berlin in 1853, and made it known to the Profession here by a paper in the *Medical Times and Gazette*, it was ridiculed as a toy, and denounced as dangerous, because the retina is sensitive to light!—yet now you hear the instrument extolled on every side by those who are learning to interpret its revelations. Some eighteen months ago I demonstrated before you, for the first time in London, the use of the *Écraseur*, and described the instrument in the *Journal* I have just named. Well, it was ridiculed in Edinburgh as a "preposterous engine," and in London as a return to the "barbarous ages of surgery;" yet every day practical men are now finding it more and more valuable. So it will be with this operation. Having overcome distrust and indifference, it is now on the fair way to general favour.

*Thirdly.* You will be told that we want no radical cure for hernia; that the palliative treatment is sufficient; that a good truss is far better than any radical cure. There is some plausibility here, but let me remind you that the fatality after operations for strangulated hernia is very great, and that a large proportion of those who become the subjects for these operations have worn trusses. The trusses have not proved a safeguard against strangulation; nay, by causing thickening of the sac, and contraction of the hernial apertures, they have increased the danger of strangulation when it has taken place. Then all trusses are not good, and good trusses are expensive. They get out of order, and patients get careless and do not keep them in order; and even when good and in order they are very insecure safeguards in sudden and violent motions of the body, or in cases of long-continued exertion. Besides, those who wear trusses will tell you that it is not pleasant to have to wear them all their lives, and carry about with them a constant memento of bodily imperfection and possible danger. Contrast this with the three weeks' confinement to the house, and the subsequent safety obtained by the operation I have brought before you, and I do hope you will do your best to assist in hastening the general recognition of its value.

## ORIGINAL COMMUNICATIONS.

### ON THE PAINLESS EXTIRPATION OF CANCEROUS GROWTHS.

By JAMES ARNOTT, M.D.

ALTHOUGH cancerous affections are, as a general rule, better treated by other and milder measures than by operation, it must be admitted that there are exceptions to this rule. These exceptions would be more numerous if any safer mode of extirpating cancerous growths could be substituted for the two measures at present employed, namely, excision by the knife and destruction by caustic. So dangerous or otherwise objectionable are both of these measures that many judicious practitioners have doubted whether it would not be preferable on all occasions to allow the morbid part to remain than have recourse to either. Statistical inquiries by Mr. Paget, M. Lebert, and others, show that at least a tenth part of those upon whom operations with the knife have been performed have died in consequence of them; and although the use of caustic is not immediately fatal to the same amount as excision, it cannot be doubted that the excessive and long enduring pain to which it subjects the patient—a pain far too acute to be subdued by opium, and far too lasting to be prevented by chloroform—must, by weakening the constitutional powers, precipitate the relapse of cancer, as well as predispose to other disease.

A means of extirpating malignant growths, unattended with pain and productive neither of shock, inflammation, nor permanent debility, would not only be free from immediate danger, but by relieving the patient's sufferings, and removing a perpetual source of irritation, would strengthen the constitution and put it into the most favourable condition for overcoming the tendency to relapse. I have discovered that such a means exists in the combination of long continued congelation with caustic.

Although I had been for some time aware that this expedient constituted an infinitely better mode of extirpating cancerous growths than either excision or caustic, I was unwilling to bring it forward without the most indisputable evidence of its excellence. On this account permission was requested of the Governors of the Middlesex Hospital to exhibit in its cancer wards what I had already ascertained respecting the use of long continued congelation in cancer, and to prosecute other inquiries in connexion with it. A brief report of the truths which I was able to establish by this liberally granted permission, will not, I conceive, be an unintended communication to the Profession.

My first and principal object was to show that cancerous growths may not only be extirpated by congelation and caustic, without pain, but if not absolutely without danger, with much less danger than accompanies the means usually employed for this purpose. This was satisfactorily fulfilled by the following case, which was watched by the surgical staff and students of the hospital, and seen by several eminent Surgeons unconnected with that institution.

On the 28th of November, at noon, Sarah H., No. 1, Luffan Ward, had a circular portion of the right breast, three inches and a-half in diameter, and enclosing a large occult cancerous tumour, congealed for two hours by a frigorific mixture, at a temperature ranging from 8 to 12 degrees below zero Fahr. This mixture, which was frequently renewed, was confined to the part by a cup or broad flat ring of gutta-percha, having a short flexible tube, closed by a stop-cock, issuing from its lower border. Immediately after removing the mixture, nitric acid was applied to the skin, and after the acid a thin layer of chloride of zinc paste was placed on it, and allowed to remain until the next day. There was no expression of pain made during or after these proceedings, but being questioned on the subject, the patient stated that for about five minutes, while the congelation was being effected, there was a sensation of tingling like that produced by a mustard plaster. The uneasiness from this was not sufficient to interrupt her account of the origin and progress of the disease, which I had requested her to give just as the congealing process commenced. This tingling of short duration was the only disagreeable feeling experienced during the day. She took her usual

dinner while the congelation continued, and slept well during the night. It is proper, however, to relate that previously to the application of the strong frigorific mixture, I had taken pains to benumb the part very gradually; and after its removal another refrigerating mixture was applied for about eight hours over the chloride of zinc, but kept separate from it by a very thin intervening membrane.

By the middle of next day, a large white slough or eschar had been produced by the combined measures, of exactly the dimensions of the lower opening of the gutta percha vessel, which (from having been previously heated) had adhered firmly to the breast till midnight. For the purpose of ascertaining the extent of the disorganisation, the slough was cut in the presence of the resident Medical officers to the depth of an inch without causing the least sensation. No inflammation followed, nor did any redness appear at the margin of the slough till the third day, when its separation had probably commenced. Notwithstanding the continued action of the caustic (which was daily inserted in the manner practised by the French) the patient's general health remained undisturbed until she left the hospital. The lower part of the eschar separated on the 21st December, and when I last saw her at her own residence on the 7th of January the cicatrisation was nearly complete. As her appetite had remained good during the whole of this period, and she had been able to take exercise in the open air, her strength continued unreduced. There had been no occasion to have recourse to cold again for its anæsthetic effects, and the only medicine taken by her during her stay in the hospital was two laxative pills.

I have not considered it necessary to describe minutely more than the first stage of the treatment; for, as my principal purpose was to show that the dreadful pain produced by caustic can be certainly prevented while its action is much promoted, and the hazardous use of the knife superseded by a comparatively safe measure, a report restricted to that part of the treatment in which the suffering has always been the most acute and the inflammation greatest, would have been sufficient. Whether it proceeded from the deep and lasting preliminary congelation, or from her not having been rendered morbidly sensitive by the very severe suffering that has usually ushered in the treatment by caustic, the patient hardly felt what could be termed pain during the whole period—except on one occasion, when a little of the chloride of zinc paste spread from the slough to the adjoining sound skin.

The absence of all inflammation, excepting that slight degree which is necessary for the separation of the slough, is as remarkable a circumstance in the above case as the absence of pain, and, in respect to danger is, perhaps, still more important. I have on several occasions endeavoured to draw the attention of surgeons to the important fact, that congelation judiciously employed often constitutes an unfailing preventive of inflammation; but no evidence of this can be more satisfactory than a statement recently made by Dr. V. Pettigrew, and reported in the *Medical Times and Gazette* of the 5th Dec., 1857. So completely is all injurious or excessive inflammation prevented by intense cold in incised wounds, that of ninety-three operations performed by him under it, and of which ninety were perfectly painless, only one did not heal by the first intention when this was desired(a).

Questions of considerable importance as respects the removal of growths by congelation and caustic are, whether one slough should be allowed to separate by the natural process before another is formed; whether a fresh slough should be made under a previous one; or, finally, whether the sloughs produced should be removed by some mechanical or chemical means, in order to give these combined measures ready access to the living parts beneath. Each of these plans may be the most appropriate to certain cases. The first is the most tedious, unless a very powerful and deeply operating combination of these agents be employed, and in that case there is danger of the destruction of texture extending too far. The making of incisions in the slough for the insertion of caustic has been practised for the last fifteen years by M. Girouard, a

physician at Chartres, though it is uncertain whether Canquoin, the celebrated cancer-curer, did not precede him in the use of a similar method. The surgeons of the Hospital at Chartres sometimes burn holes with cylinders of caustic potash and lime, into which they insert pieces of chloride of zinc paste; and, more lately, caustic has been inserted deep in the flesh, either by previously puncturing the part with a knife (the practice of M. Maisonneuve), or by injecting liquid caustic through a capillary tube. (b)

When perfected, the third plan will probably be the best. The slough formed by intense cold could be easily removed by bent scissors, and under congelation, without uneasiness. Still softer, and more easily removable, is the slough produced by alkaline caustics, and the objections to them hitherto may be obviated by using the gutta-percha cup in their application. They are thus prevented from spreading, and any hæmorrhage produced by them can be immediately checked by chloride of zinc, or by extreme cold alone. The contrivance of the cup will also enable us to soften or dissolve the harder eschars formed by the mineral acids or metallic salts. I am now engaged in investigating this subject (c).

The union of pressure with frigorific agents facilitates the extension of congelation, by arresting the circulation through the part. They may be combined in a variety of ways, such as by pressing on the part a metallic vessel filled with a frigorific mixture; dipping such a vessel into mercury, confined to the part by a gutta percha cup; pressing a surface under the action of a frigorific, with a cylinder of wire-work; compressing the air in a close cup, containing a refrigerating mixture, etc. These plans complicate the process, but under certain circumstances their adoption may be indispensable.

The combination of disorganizing and benumbing cold with caustic renders it of less importance to terminate the process of extirpation speedily. The extreme sufferings of the patient under the usual caustic treatment have too often induced the Surgeon to hasten the removal of tumours, at the risk of leaving some portion of the disease behind.

It was my intention, after describing the mode of removing tumours by the combination of intense cold with caustic, to enter upon the question, whether congelation, sufficiently prolonged, might not alone answer the same purpose, and, on some occasions, more advantageously. In two cases at the Middlesex Hospital this method was adopted, and with results of a very satisfactory nature, the description of which, however, as this paper has already exceeded its proper limits, must be deferred to another occasion. I will only state that these trials showed that the destruction of cancerous growths can be effected in as well-defined a manner by intense cold alone, as by its combination with caustic, but that the part must be kept thoroughly congealed for several hours. Such slow destructive action, though an inconvenience as respects this particular use of intense cold, is a fact of immense value in reference to its employment for operations and other remedial purposes, inasmuch as the knowledge of it will dispel the fear of injury to the textures which has hitherto impeded these uses of it. It were unreasonable, however, to consider the difficulty and trouble of pursuing this treatment of cancer, as an objection to it. Difficultly, if surmountable, is no sufficient reason for rejecting a remedial measure, for which there is no substitute; and no conscientious practitioner will object to what is requisite for his patient's safety, or freedom from suffering, merely because it is troublesome. Besides other advantages, the far-pervading influence of congelation may be absolutely required to destroy the vitality of those germs of the disease that lurk in places which cannot safely be invaded either by the knife or caustic; for extreme cold, as I have explained at length in my work on "Cancer," will destroy the cells and granules constituting the essence of the disease, without injury to the structures enveloping them.

50, Baker-street.

(b) In my "Essay on the Present State of Therapeutical Inquiry," published in 1846, a screw syringe for this purpose is described.

(c) In the November number of the *Edinburgh Medical Journal*, Mr. Syme speaks of this use of gutta percha as an invention emanating from the Royal Infirmary of Edinburgh. Considering that the contrivance may be usefully extended to other purposes, as in applying water directly to a part by means of the current apparatus, I think it worth while to state that my pamphlet on "Chloroform," containing the suggestion of applying a mineral acid in a flat ring or open cup fitted to the part, was in the hands of three of Mr. Syme's colleagues at the Infirmary in August last; and that I have, three years ago, described such a ring of gutta percha as a convenient mode of limiting the action of frigorific mixtures in certain operations in my treatise on "Benumbing Cold," page 10.

(a) It is very possible, however, by continuing the cold too long, to reduce the vital powers beyond the degree required for union by the first intention. This happened some time since, in two cases at Guy's Hospital, under the care of Mr. Birkett. From the congelation having been continued at least four times longer than was necessary, the wound healed slowly and by granulation.

## WOUND OF THE POSTERIOR TIBIAL ARTERY.

SECONDARY HÆMORRHAGE—DELIIGATION—RECURRENCE OF HÆMORRHAGE FROM LOWER ORIFICE—DELIIGATION—RECOVERY.

By J. C. WORDSWORTH, Esq.

Assistant-Surgeon to the London Hospital, etc.

William Smith, aged 33, a labourer, was brought to the London Hospital, September 6, 1857, having wounded himself with a narrow sharp-pointed knife, while engaged in cutting cabbages. The wound was about an inch in length, oblique in direction, and situated at the lower third of the left tibia, on the inner side, and in the fleshy part of the leg. On probing the wound, it appeared about three quarters of an inch in depth. The patient stated that the infliction of the wound was followed by an immediate gush of blood, which spirted out to some distance, and that a considerable quantity had flowed. As there was no bleeding, the wound was closed by sutures, and a compress.

Sept. 7.—Going on well; the dressings remained unchanged.

8th.—The foot swollen and painful. The bandage somewhat saturated with blood, which had oozed from the wound since early morning. On removing the compress there was considerable hæmorrhage, much of which appeared, however, of venous character. Mr. Forbes, the House Surgeon, enlarged the wound downwards about an inch. With some difficulty he succeeded in tying a bleeding vessel, but was unable to find its lower orifice. From the comparatively superficial situation of the artery, it was considered to be a muscular branch. The hæmorrhage ceased, and the wound was dressed with lint dipped in iced water; the limb was elevated, and left uncovered.

9th.—The wound had a very unhealthy aspect; hæmorrhage recurred, but was controlled by the tourniquet on the femoral artery.

10th.—Since last report, he had lost blood on two or three occasions, and once copiously. Mr. Wordsworth was requested to see him, and at once decided on the propriety of endeavouring to secure the bleeding vessel. Chloroform was administered, and the wound dilated to the extent of about four inches, and on removing some coagula the posterior tibial artery and nerve were found—the former completely divided, the latter partially so; blood, of brick-dust colour, was flowing freely from the lower orifice, which was therefore secured by ligature. The upper part of the artery had retracted, and was lost in the softened tissues; all bleeding ceased, and the wound was closed by strips of wet lint, and a bandage lightly applied from the foot to the knee.

No more bleeding occurred, and the man made a good recovery, and left the hospital quite well. The above case, for the particulars of which I am indebted to Mr. Mackenzie, the dresser, affords some points of interest and of practical importance deserving a few comments. In the first place it illustrates the physiology of wounded arteries in a particular manner. Secondly, it demonstrates the accuracy of modern Surgery; and lastly, it enforces the importance of complying with the established deductions of science. We see that though the means adopted by nature sufficed to arrest the hæmorrhage in the first instance, yet that as soon as the collateral circulation was established, bleeding recurred from the lower orifice; and remembering the large and direct communication between the posterior tibial, and peroneal arteries, we should have anticipated that event, for physiology teaches that the contraction and plugging of the lower end of an artery are very imperfect, and therefore easily overcome; but that in the upper these means suffice if not disturbed for some hours.

Again, on the recurrence of bleeding, it was noticed that it oozed slowly for some time, and was of venous character, and that the vessel then ligatured was probably divided in the necessary dilatation of the wound, and not the posterior tibial artery; and as no ligature was found in the subsequent operation, it is probable that such was the case, for it could not have separated in the interval from the large artery. Then, as the bleeding recurred after the vessel had been secured, it was at once decided to enlarge the wound, and follow the artery to its bleeding point. Under the presumption that the hæmorrhage came from below, the wound was extended downwards,

principally in the course of the artery, with a view of tracing it upwards, if, as often happens in these cases, the bleeding orifice was lost in a mass of softened tissues and coagulum. Considerable difficulty was experienced in controlling the flow of blood, part of which was venous. The coagula being removed, the nerve was at once found, and afforded a good clue to the artery; by a little dissection it was separated from its sheath, and a ligature passed around it by means of the aneurism-needle, and secured. This case also fully confirms the dogma that no delay should occur in securing the lower end of a vessel when there is reason to consider it the source of hæmorrhage, as the prospect of Nature's closing the orifice is very uncertain.

Lastly, it determines the importance of attempting, without delay, to secure a bleeding artery of large size, when there is a fair presumption of its having been wounded, provided the artery can be ligatured at the seat of injury.

## SERIES OF CASES ILLUSTRATIVE OF DISEASES OF THE ABDOMEN, AND ESPECIALLY OF THE DIAGNOSIS AND TREATMENT OF ABDOMINAL TUMOURS AND INTUMESCENCE.

By CHARLES J. HARE, M.D. Cantab., L.R.C.P.

Assistant-Physician to University College Hospital, etc.

### MOVEABLE KIDNEYS—THEIR DIAGNOSIS AND TREATMENT.

(Continued from p. 9.)

*Symptoms, etc.*—The symptoms presented in different cases of this condition of the kidneys, vary considerably, but as there is not necessarily associated with it any structural change in the organs themselves, they are, as might *a priori* be expected, chiefly of a local character. In some instances, indeed, no pain or inconvenience whatever has been experienced by the patient, and the presence of the affection has been only accidentally discovered. In by far the majority of cases, however, certain symptoms are present which, if not altogether characteristic of the affection, should at least make us suspect the possibility of their dependence upon it, and should therefore lead us to an examination of the abdomen, so as to determine whether it be present or not. The symptoms most frequently complained of are a feeling of uneasiness or weight about one or both loins, but much the most commonly the right one; or a similar sensation may be experienced in the antero-lumbar region, or even lower down in the abdomen; or a so-called "sinking sensation" or "fainting pain" is referred to the same parts. Sometimes more decided pain is experienced: it is usually of a dull character, but varies at different times, and is sometimes even rather sharp; it is almost always described as being associated with more or less of a "dragging" sensation; in one case a kind of colicky pain was present. Rayet mentions an instance in which the pain extended to the lower part of the abdomen, and in the course of the crural nerves as far as the knees; and another in which it affected the back part of the thigh and leg as far as the ankle, and, commencing in the right loin, radiated to the labia majora: this patient also described the habitual pain which she experienced in the abdomen, in exactly the same words as were used by a patient under my care, namely, as of a "pinching" character.

The pains are almost invariably relieved by the recumbent posture, and are not unfrequently entirely (for the time) removed by it. On the other hand, they are increased by too long sitting, by walking or over exertion of any kind, and remarkably so by standing for any length of time. A costive condition of the bowels augments the discomfort arising from the kidneys, and the pain is also increased, according to Professor Oppolzer, during defecation. A miscarriage, in the case mentioned to me by Dr. Gueneau de Mussy, considerably aggravated the symptoms for a while.

Sometimes there is a little superficial abdominal tenderness on pressure in the neighbourhood of the displaced kidney

but this is not generally the case. In one or two cases (a), also, pressure upon the mobile kidney itself has produced no tenderness or pain, but usually (especially if the organ be seized, as it were, between one hand placed at the postero-lumbar region, and the other on the anterior part of the abdomen), it gives rise to some pain, and very frequently to a peculiar sensation of faintness: now and then it causes pain to shoot to other parts of the abdomen. One patient (Mrs. D., Case 1, *infra*) told me that when she lay on the left side, she experienced a dragging sensation from the right loin, "as if something were falling from the right side over towards the left."

I have already described the physical signs presented by the mobile kidney. In one case, quoted by Rayer (b), oedema of the right leg was caused by a moveable kidney. In four out of six cases which I have seen, I have detected a very strong aortic abdominal impulse, and in three of these cases it was so strong as to be a source of complaint on the part of the patients. One cause, probably, of the impulse in these cases being felt so strongly was this: that the same flaccid and moderately thin condition of the abdominal parietes which facilitated the detection of the mobile kidneys likewise permitted the fingers more easily to reach deeply towards the spine. But this, I feel convinced, was not the only cause of the strong impulse detected: two, if not three, of the patients were anæmic, and suffered a good deal from general debility. It has been recorded of several patients affected with moveable kidneys, that they have presented symptoms closely resembling hypochondriasis. In all uncomplicated cases the urine presents nothing abnormal.

Though the foregoing symptoms include all, I believe, which are essentially connected with a mobile state of the kidney, it must not be forgotten that other diseases may be present so as to complicate the case—the occurrence of this state not excluding, of course, the possibility of other diseases of the organ being present. Thus calculi, etc. may exist in the moveable kidney,—they have, indeed, been found in more than one case,—and may give rise to nausea, vomiting, hæmaturia, pus in the urine, etc., which are symptoms quite alien to a case of simple mobility of the kidney.

The following very brief outlines, condensed from notes of some of the cases I have observed, will tend to illustrate several of the preceding observations.

Case 1.—Mrs. D., aged 36, the mother of several children, had been occasionally under my care for several years. She had suffered from anæmia and oligomenorrhæa, but got quite well of these. I afterwards saw her for an attack of gastrodynia, when she also had much languor and debility, with weight and sinking sensation at the epigastrium.

In the spring of 1852 I attended her for a slight bronchial attack: when she got better of that she complained to me of a "beating sensation" down the middle of the abdomen, and also of having at the upper part of it, on each side, "some swellings which on pressure slipped up under the ribs." She had had a sinking sensation at the epigastrium for years, but it was only about twelve months that she had felt, on applying her hand there, a tumour in one (the right?) hypochondrium, and about four weeks, another on the other side. The aortic impulse had been troublesome for five weeks past.

On making an examination of the abdomen (which was rather thin, and of short antero-posterior diameter, while the parietes were also flaccid), the aortic impulse was found to extend from the upper part of the epigastrium to more than an inch below the umbilicus, and it was exceedingly well marked and strong. The left kidney was situated lower than usual, but readily glided, when pressed upon, from under the fingers, deep into the hypochondriac region, while, on the other hand, it might be pushed some distance downwards: the right kidney presented the same phenomena, except that it was much more mobile, and could be detruded downwards so far that the whole of it could be felt some distance below the costal cartilages, and its form well made out owing to the thinness of the parietes (see fig. 1, p. 9).

A belladonna plaster was applied to the abdomen, and some tinct. ferri sesquichlor. and tinct. columbæ were given. I

have seen her several times since, and again very recently: at times she has been free from all renal pain, but lately she has again felt somewhat weaker, and she has had more both of the abdominal impulse and of the dragging sensation in the loins, though the pain is by no means so much there as it was a few years ago. On examining the abdomen the mobility of the kidneys (especially of the left one) appeared to me less than formerly, though that of the right one was still very notable.

Case 2.—Miss A. S., aged 25, resident in the country, first came under my care in September, 1852, for dyspepsia and spinal irritation, accompanied with superficial pain in the left infra-mammary region. When I saw her about the middle of the following month, she had improved, but still complained of some pain in the left side, from the mamma to the level of the crista ili. On examining the abdomen (see fig. 2, p. 9), I detected both kidneys lower in position than usual, and moveable. The abdominal aortic impulse was also distinctly though not very forcibly felt. For some months prior to my seeing her she had complained of a "beating sensation" at the epigastrium, but had scarcely any pain referable to the kidney; indeed, as she subsequently told me, she only felt it if she walked faster than usual, and then it was "a kind of pinching sensation—not a weight."

During the ensuing twelvemonths, I had several opportunities of confirming the diagnosis as regards the moveable condition of the kidneys, but it appeared to me that though both kidneys were readily detectable and moveable, the left one was at that time rather more so than the right. Firm pressure on the left kidney gave rise to an uneasy sensation in it, but scarcely amounting to pain.

She was placed on a course of steel medicines, and became quite free from all abdominal symptoms, except a very slight amount of the "pinching sensation" when she much over-exerted herself. Indeed, I only saw her once again until the spring of last year—an interval of three and a-half years—when the accompanying diagram was taken, which shows the position of the kidneys at that time (see fig. 2, p. 9). She then complained of headache, but the abdominal symptoms, so far as her own sensations were concerned, were quite in abeyance. The urine was stated to be then, as it had been previously, quite natural. The physical condition of the kidneys, however, appeared to have altered somewhat; though the left one was quite as easily detected as before, the right one seemed to be rather lower down in the abdomen, and to be perhaps somewhat more moveable than previously. On relaxing the abdominal parietes, the right kidney was found to extend nearly two and a half inches below the level of the costal cartilages, and on deep inspiration it descended another inch downwards: by a little manipulation, when thus depressed by inspiration, the whole of the kidney could be placed below the level of the cartilages, when it assumed the more oblique position represented in the drawing. The outlines at E and F show the position of the left kidney.

It would appear that in this case the left kidney had, in the interval of between three and four years, become *relatively* less mobile, so that it could not, when I last examined her, be detruded so far downwards as the right one, though previously the more moveable of the two.

I may mention, as an interesting circumstance in connexion with the above case, that a niece of this patient (a sister's daughter), aged 21, has her kidneys considerably lower in the abdomen than is usual, and that one of them is also a little moveable.

Case 3.—Mrs. R., aged 27, married eight years; has had four children, the last one fifteen months ago.

This case presented an example of one kidney being moveable to a very considerable extent, while the other one occupied the normal position, and was not affected with any unusual mobility. The right kidney, as she lay on the back, extended some little distance below the costal cartilages, but it was very easily moveable so far down in the abdomen that the lower end reached to a point five inches below the costal cartilages, at the mid-sterno-nipple line, or two below the level of the umbilicus (fig. 3.) The entire kidney could thus be seized between the hands, and its size pretty accurately estimated. As thus ascertained, it measured four and three quarter inches in length, by three and one-eighth

(a) Gazette Méd. de Paris, 1846, p. 993. In the case of Miss A. S., the tenderness or pain was exceedingly slight.

(b) Rayer, loc. cit. vol. iii. p. 791.

in breadth; it did not, therefore, exceed the average dimensions.

FIG. 3.

Moveable kidney of one side only.

(To be continued.)

## THE LONDON PRACTICE OF MEDICINE AND SURGERY.

### THE CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST. ILLUSTRATIONS OF THE TREATMENT OF THROAT AFFECTIONS.

(Cases under the care of Drs. PEACOCK, BENNETT, and BIRKETT.)  
(Continued from page 61.)

**Case 4.—Chronic Laryngitis, with symptoms of impending phthisis.**—Six months' treatment by cod-liver oil and topical counter-irritants.—*Recovery.*—Peter Burness, aged 46, a warehouseman, was admitted on May 4, 1854, under the care of Dr. Bennett, when the following notes were taken:—"Voice hoarse, and all but lost. He states that he has been gradually losing it for the last eighteen months, during which time he has been out of health, and slowly emaciating. He has several times spat blood in small quantities, and for a year past had had a troublesome cough. His aspect is phthisical; nails incurved; pulse quick; tongue coated. The physical signs are, however, not decisive of phthisis. The throat is relaxed, streaky, and congested. He has had but little treatment." Dr. Bennett prescribed two teaspoonfuls of cod-liver oil to be taken three times a-day; and for a night-dose two pills, containing five grains of the compound squill pill, one of blue, and three of Dover's powder. The throat was also ordered to be painted externally with the strong solution of iodine, and the nitrate of silver to be applied to the larynx by means of the probang.

On May 18, the treatment having been steadily continued, the note states: "No soreness of gums, but the voice is much improved. Much difficulty has been encountered in using the probang, on account of the irritable state of the fauces, and it is not certain that the sponge has ever really reached the larynx. The mercury is to be omitted from the pills, and the treatment continued."

July 13.—Voice improving.

August 3.—Much better in every respect. The solution of iodine has been repeatedly applied outside the throat.

31st.—Has been for a fortnight to Brighton. The voice continues to improve.

Sept. 14.—To omit the oil, and take in its stead the compound decoction of bark, with dilute hydrochloric acid, three times daily.

This case ended in most complete recovery. It was judged well to continue the tonic treatment for some time after the voice had regained its clearness, and on the date of discharge (Nov. 23, after rather more than six months' treatment) the note taken was as follows: "He has now a good clear voice, and for two or three months past it has been so without any relapses. He looks well, is florid, and can walk fairly. Is as stout as he ever was, and feels much stronger than this time last year. Pulse 100. Free respiratory sounds over both apices, and no dulness over either."

While there is every reason to believe that true chronic laryngitis is far more common in men than in women, due no doubt to their much greater exposure to the inclemencies of weather, yet cases of loss of voice are perhaps on the whole more frequent among the latter. Hysterical aphonia constitutes a considerable class, but a far larger one is that in which a hysterical predisposition aggravates a slight catarrhal affection, and renders it very difficult to cure. A delicate, susceptible woman takes cold, and has a slight pharyngitis, there is some discomfort in speaking, and the voice is not clear. Upon this she forthwith becomes wholly aphonic, and the aphonia probably lasts some weeks, while, had one of the sterner sex been the subject of precisely the same original condition, a hoarseness would have been all that would have resulted, and even that would probably have soon been got rid of. These cases are very likely to be followed by relapses, and as is well known, many women "lose their voices" whenever they take cold. We need not cite many or lengthy examples of these so common cases, in which the hysterical diathesis complicates a slight inflammatory affection, and exaggerates it into a very troublesome one. Besides, they are much more often met with in private than in Hospital practice. The completeness of the aphonia, while there is scarcely any laryngeal ring on coughing or attempting to speak loud, and the occasional very sudden improvements which take place are diagnostic symptoms. The treatment must address itself to the double cause, the nervous temperament and the local congestion. Severe counter-irritants to the throat do not appear to be generally serviceable, nor do powerful applications to the larynx. Stimulant gargles, protection to the throat, and nervine tonics appear to be the most useful remedies. Sometimes a blister at a distance, as to the nape of the neck, is very useful. The following case exemplifies these remarks:—

**Case 5.—Hysterico-catarrhal aphonia.—Fourth attack.**—*Treatment by sulphate of zinc and blister to nape of neck.—Recovery.*—Sarah Cherry, aged 41, married, but childless, was admitted under Dr. Peacock's care, on August 5, 1853. She stated that on three former occasions she had lost her voice for a few weeks at a time after taking cold. On the present occasion the aphonia, which was complete, had lasted ten days. She complained of much sense of choking and spasm in the throat. Her cough was very troublesome, but was not attended by expectoration. She was stout, and rather florid. Dr. Peacock ordered a turpentine liniment to be rubbed on the throat, and a draught to be taken three times a-day, containing an ounce of the infusion of valerian, two grains of the sulphate of zinc, and twenty minims of the tincture of hyoscyamus.

These remedies were continued up to August 26, when, as no improvement had resulted, it was determined to try the effect of painting the throat with the strong solution of iodine. This was done freely, but the note on Sept. 2 states that it was followed by no improvement.

On September 9 Dr. Peacock ordered a blister to be applied to the nape of the neck. The mixture was continued.

The note on September 16 states that while the blister was sore she regained her voice, and for a whole day spoke quite clearly. Afterwards, however, she relapsed, and became almost as aphonic as before. The mixture was continued.

On October 14 she was discharged nearly well, the affection having gradually passed off.

The relative proportions of the two elements in this mixed affection may vary very considerably, and just in proportion to the amount of the local disease as evidenced by hoarseness, laryngeal twang, persistence, etc., is the indication for the employment of local counter-irritation. The following cases illustrate this rule of practice.

**Case 6.—Very Chronic laryngeal aphonia in a delicate woman.**—*Treatment by counter-irritants and tonics.—Recovery of the*

voice.—Elizabeth Chesshire, aged 30, was admitted under Dr. Peacock's care on September 19, 1854. She was married, and the mother of five children. Her voice was a soft distinct whisper, but the cough was rough and very hoarse. She had pain in the effort to speak loud. She stated that she had been aphonic without intermission for two years, and that twelve years ago she had suffered from a similar state of things for five months, and then regained her voice. During the last year she had lost flesh greatly, but had never spat blood. Her father had died of phthisis at the age of 32, but her mother was living and healthy. Ordered two teaspoonfuls of cod-liver oil twice daily, with a draught containing quinine and iron, also to have the throat freely painted externally with the strong iodine solution.

The above remedies were steadily continued, and on Oct. 24 the painting was repeated. On Oct. 31, the note states, "She can speak almost clearly;" and on Dec. 12 it is, "The voice is quite clear." She had not at this latter date, however, quite regained her health, and she was accordingly advised to continue the tonic, etc., a few weeks longer; but a miscarriage occurring, she soon afterwards ceased to attend. While under observation her voice had remained clear.

(To be continued.)

## THE ROYAL LONDON OPHTHALMIC HOSPITAL.

### REPORT OF OPERATIONS PERFORMED FROM NOV. 25TH 1857, TO JAN. 1ST, 1858.

(Communicated by Dr. C. BADER, Curator.)

#### LACHRYMAL APPARATUS.

Three cases of diseased lachrymal sac treated with the actual cautery. In two (probably incompletely) treated in this manner before, the discharge had reappeared, and cauterisation was performed a second time.

In another case of distension of the sac by pus an attempt was made to carry a thread through a skin incision, the sac, and nasal canal, and out by the corresponding nostril, and by gradually increasing the thickness of the thread, to produce a permanent distension of the nasal duct. On account of some defect in the spring to which the thread was attached the attempt failed, and the actual cautery was resorted to.

Another case of distension of the lachrymal sac by tears and mucus was caused by a polypus in the corresponding nostril, which appeared to press upon the nasal duct. Mr. Wordsworth removed the greater part of it, which at the time allowed the contents of the sac to escape on pressure into the nose and mouth. In another case No. 6 probe was passed through a fistulous opening in the skin over the sac into the nasal duct and the nose. The further treatment consisted in frequently emptying the sac into the nose by pressure. (This case is progressing very favourably, and the fistulous opening has closed. It certainly is advisable to try this plan before resorting to Desmarre's treatment of entire destruction of the sac.)

#### EYELIDS.

Excision of a hazel-nut sized pediculated sebaceous tumour from the skin, near the inner canthus, and in another case of a naevus, situated on the outer upper portion of the left eyebrow. The hairs which grew on it were pale, and inferior in development to those of the remainder of the eyebrow.

In a case of malformation of the palpebral aperture, after excision of the globe, an oval piece was removed from the middle of the inner aspect of the lower lid, leaving the skin intact. After uniting the wound with sutures, the palpebral aperture was thought to be sufficiently narrow to retain a glass eye.

The treatment of a severe case of ectropium was commenced by slitting open the lower lachrymal canals.

Another case of ectropium was operated upon by grooving the fibro-cartilage, near and parallel to the palpebral edge. To prevent troublesome bleeding during the operation, a compressorium forceps (see Desmarres, second edition) was used. This manner of operating leaves the palpebral edge entire.

#### MUSCLES OF THE EYEBALL.

Internal strabismus; subconjunctival division of the internal rectus eighteen times. In seven cases both internal

recti were divided; in many cases the improvement of vision was immediate. In one case (Mr. Poland) of congenital double external strabismus with muscæ (not seen with the ophthalmoscope) both external recti were divided, both eyes are straight, and the muscæ have entirely disappeared from one eye.

#### CORNEA.

In two cases of staphylomatous protrusion of the iris, the staphylomata were punctured with a needle, to allow some of the distending fluid to escape; a compressive bandage was then applied.

One case, in which the central portion of each corneæ was occupied by a brown, well-defined deposit (appearing nine months ago, during the use of some white eye-water); in the one eye a portion of the deposit was removed from opposite the pupil, by sliding a sickle-shaped knife under it, producing an edge, and dissecting it off with the knife and forceps. At present the pupil of this eye is opposite transparent cornea. The deposit consisted (500) of minute light-brown, round granules, adherent to each other, and fringed by transparent corneal tissue.

#### IRIS.

Formation of an artificial pupil in six cases. In four of them three-fourths of the cornea were opaque, and in two that portion opposite the pupil. In five cases the broad needle was introduced through that part of the sclerotic nearest the transparent cornea, and an incision made sufficiently large to admit the canula forceps, the iris was then seized, drawn out, and snipped off with scissors. In the last case, in which the central part of both corneæ was opaque, Mr. Bowman operated on the right eye by opening the cornea near its lower edge with the broad needle, then drawing out the iris with the blunt hook, and snipping it off with scissors. On the left eye, in which the pupil appeared to be adherent, he seized the iris with the canula forceps near the pupillary edge, leaving the drawn out piece in the corneal incision. The eyeball, which had been oscillating before the operation, remained so when the patient left the Hospital after fourteen days. She reads large letters with the left, and recognizes large objects with the right eye. Formation of an artificial pupil in both eyes in one case, and on one eye in a second, in which the cornea was transparent, the pupil adherent and occluded, and no inflammatory symptoms present; the cornea was opened at its lower and outer transparent edge, the blunt iris hook inserted, and at the margin of the pupil where it was adherent a piece of iris withdrawn and snipped off; the patient left the Hospital six days after the operation, and reads large type with either eye.

In a case of adhesion of the iris to a corneal cicatrix, Mr. Bowman's needle-hook was introduced through the transparent cornea furthest distant from the adhesion, advanced to the latter, and the piece of iris withdrawn and left in the corneal wound.

Two cases of detachment of iris adhesions in the pupillary area; the adhesions easily detached by moving the blunt spatula between them and the capsule—the pupil at once regained its round shape but vision remained as before the operation. Excision of the upper third of the iris for treatment of chronic glaucoma in the right eye, with which the patient could only distinguish lines on a printed page. The left eye was slightly misty, but as he was still able to read any type with it, it was not operated on. The patient was in the Hospital from the 18th to the 29th December; the blood which filled the anterior chamber immediately after the operation, had disappeared within eight days. The patient on leaving sees to read well small letters with the right eye. The cupped appearance of the optic nerve at its entrance is less distinct.

#### CRYSTALLINE LENS.

Extraction of Cataract.—Case 1.—E.B., aged 54. Commencement of cough six years ago, of dimness of vision three years ago; at present both lenses of unequal gray colour, the eyes otherwise normal; perception of light with either eye. Double extraction by upper corneal section. 4th December, 1857. Some bleeding from the conjunctiva; course regular; left Dec. 21, 1857. Central pupils; reads with glasses any type with either eye.

Case 2.—E. T., aged 65. Both lenses opaque; general health good; commencement of cataract six years ago, temporarily relieved by leeching. Left lens most advanced, sees large objects with it; extraction of the left lens by an upper corneal section. Dec. 2, 1857.—Course regular. Left Dec.

14, 1857.—Central pupil; reads any type with glasses, and sees to do his work.

*Case 3.*—C. H., aged 20. Congenital cataract and external strabismus of the left eye, perception of large objects. Right eye normal. In pupillary area of left eye when under atropine is seen suspended a yellowish-white disc, on whose surface particles of chalk are visible. Dec. 18.—Mr. Critchett first divided subconjunctively the external rectus, then removed, through a small corneal incision, part of the lens with the canula forceps, and the remainder with the scoop; then re-introducing the broad needle, the posterior capsule was opened, and part of it extracted with the canula forceps; the pupil became black and dilated by the advancing vitreous humour. Left the Hospital 19th Dec. On the 22nd December the patient reads large type with glasses; the conjunctiva slightly chemotic; the pupil extremely dilated; lacrymation. (Under treatment as out-patient.)

*Case 4.*—H. E. R., aged 11, congenital cataract in both eyes, perception of large objects, colour, etc. The patient has been for several years in an asylum for idiots. Dec. 24th.—The left lens superficially broken up with one needle by Mr. Dixon; the central white disc on the grey substance of both lenses, easily detached, and projected with some soft lens matter into the anterior chamber. Dec. 28th.—Attends as out-patient.

*Case 5.*—I., aged 33. Cataract in right eye from accident sixteen days ago. Cornea transparent; part of the soft lens matter scooped out through a small corneal incision eighteen days after the injury; more perception of light after the first operation. Thirteen days afterwards the greater part of the remaining lens substance was scooped out; the patient immediately recognized people, and six days afterwards left the Hospital.

*Case 6.*—D. A., aged 19. Detachment of the iris followed by cataract, linear extraction; the patient sees at present to recognise people. Duration of treatment seven days.

*Case 7.*—T. S., aged 26. Sequelæ of former inflammation of the globe, right eye; the iris dragged into a corneal cicatrix near the outer lower edge, the cornea flattened and wrinkled, the globe softened and squared; perception of light. Operation December 2. The broad needle introduced at the outer corneal edge was advanced between the cornea and iris to the middle portion of the latter; then thrust through it, and the wound enlarged on withdrawing the needle. December 21.—With this eye the patient sees the window well. Left eye softish; the area of part of the pupil occluded by a chalky deposit; the patient recognizes features with this eye. December 2.—Operation; the corneal incision about four lines long; detachment of the deposit with scoop and iris forceps; considerable force was used in doing this, one-third of the fluid vitreous escaped. December 21.—Central irregular pupil; no pain or inflammation. The patient sees large print; no active inflammatory symptoms were present before these operations.

Six cases of false membranes in the area of the pupil treated with one or two needles; among them was a case of congenital cataract, in which both lenses had several times been touched with the needle; at present the lenses give the impression of flattened grey membranes, which Mr. Streetfield opened out with two needles, when the vitreous humour advanced dilating the pupils; on first sight such a black pupil is very satisfactory, and in several cases the result was favourable, and was not disturbed by inflammatory symptoms; in other cases this admission of vitreous humour into the pupillary area was followed by sickness, and severe pain and other inflammatory symptoms in the eye.

#### EXCISION OF THE GLOBE.

*Case.*—D. H., aged 13. Removal of the right globe; general staphylocoma after purulent ophthalmia; hardly any bleeding. Left the Hospital three days after excision.

## ST. BARTHOLOMEW'S HOSPITAL.

### LIGATURE OF THE COMMON CAROTID ARTERY.

(Under the care of Mr. COOTE.)

(Reported by Mr. CHIFFENDALE, House-Surgeon.)

E. B., an agricultural labourer, aged 64, was sent from the country on account of a fungoid disease of the right superior maxillary bone. He states that he first noticed an enlarge-

ment of that side of the face about three months ago, and that he has not suffered much pain. Its growth has since made very rapid progress, for it has already acquired the size of a small clenched fist. The features are, of course, much distorted; the nose is pressed over to the left side, and the right nostril is distended by the morbid growth, so that its passage is completely occluded. The vision of the right eye is also interfered with, owing to the extension of the disease upwards. The tumour projects into the mouth, and can be felt as a soft semi-elastic body to descend into the upper part of the pharynx, the soft palate being thrust forwards. The condition of these parts renders deglutition difficult. The skin over the tumour is tense, and in parts red and shining, as if inclined to ulcerate. An operation for its removal was not thought advisable, considering the extent and rapid growth of the disease, the age and weak condition of the patient. During the short time that he remained in the Hospital the tumour greatly increased in size, becoming one-third larger, while at the same time his strength rapidly diminished from his inability to take sufficient nourishment, and from the frequent hæmorrhage that took place from the nostril and the portion of the growth which protruded into the mouth. This latterly occurred on the average about every other day, and frequently amounted to a half pint, the blood flowing in a full continuous stream, and being with difficulty checked.

As the patient was rapidly becoming exhausted from these repeated attacks of hæmorrhage, Mr. Coote decided upon tying the common carotid artery. The vessel was secured about half-way between its origin and its termination, below the point where the omo-hyoid crosses. No hæmorrhage subsequently occurred from the tumour. Paralysis of the opposite side came on in about thirty hours after the application of the ligature. The man sank on the third day. On a post-mortem examination the right hemisphere was found to be of a softer consistence than the left. With this exception, no difference was to be observed in the condition of the two hemispheres.

The diseased growth proved to be encephaloid, and appeared to have had its origin in the antrum, the cavity of which was filled with a soft, easily-broken-down mass. The disease had made its way through the orbital plate, and also had almost filled the nasal fossæ.

The examination of the artery about the seat of ligature was especially interesting, as the opportunity of examining the state of a large vessel, so soon after an operation of this kind, does not often present itself. Below the ligature there was a small, pale, delicate coagulum, rather more than half an inch in length, very loosely connected with the coat of the artery. Above the ligature there was a similar clot, but of less size, scarcely exceeding a quarter of an inch in measurement.

## HOSPITAL NOTES.

### AFTER-TREATMENT IN CASES OF LINEAR EXTRACTION.

Mr. Bowman made some remarks the other day respecting the after-treatment of cases in which linear extraction had been performed. The chief point on which he insisted was, that belladonna ought always to be employed, and the pupil kept dilated to the utmost. Very frequently, he observed, small portions of lenticular matter remain which, if allowed during the inflammation which follows to press upon the iris, may cause much irritation. To prevent this was the object of the belladonna treatment. A second point to which he adverted was that the Surgeon ought not to allow himself to feel too confident that all would go on well, but should watch the case just as carefully as after more serious operations, and be prepared promptly to interfere should indications of inflammation of the globe ensue. He had in one case known the globe to suppurate, proving that the operation was not so entirely devoid of danger as might be supposed.

### EMPLOYMENT OF SUGAR IN THE DYSCRASIA ATTENDING BRONZED SKIN.

Dr. Todd, in a case of bronzing of the skin, now under his treatment in King's College Hospital, has ordered the free dietetic employment of sugar. The patient, a woman, is believed to have derived considerable benefit from it in relief

to the malaise and debility from which she suffered. The theory of the treatment is, we believe, based on the belief, founded on analysis of the blood, that the sugar-making function of the liver is interfered with by the disease. The suggestion is certainly well worth a trial, since the treatment can at any rate do no injury.

#### LARGE MALIGNANT TUMOUR IN THE ABDOMEN —DIFFICULT DIAGNOSIS.

An autopsy was performed the other day on a patient who had died, under Dr. Ramskill's care, in the Metropolitan Free Hospital, which illustrated remarkably the difficulty of forming a correct diagnosis respecting certain abdominal tumours. An elderly woman had suffered for nearly a year from a tumour, which she attributed to a blow on the epigastrium. At the time of her admission it was very large, and distended the upper half of the abdomen. The percussion note was dull from the thorax downwards to a level of about a handsbreadth below the navel, where the tumour ended in an irregular nodose border. In the left side and lumbar region it was very prominent, and distinctly fluctuating. In all other parts it appeared solid. At first the liver only was suspected as its seat; but the discovery that the transverse colon, empty and contracted, crossed over its surface, altered this opinion, and led to the belief that there must be a large secondary growth from the lumbar glands or spine. The functions of the stomach and intestines were remarkably little interfered with, considering their very altered positions. At the autopsy the growth proved to be an enormous mass of medullary cancer developed from the lumbar glands. The liver was healthy and small, but pushed upwards by the tumour, with which it was in close apposition. The stomach was quite empty, and compressed by the growth upwards and backwards. There was thus no space between the tumour and the liver over which the percussion note could have been clear, and hence the impossibility of ascertaining that the liver itself was not involved.

#### TREATMENT OF ECZEMA ON THE EARS OR SCALP.

Mr. Startin is accustomed to teach, as a practical rule in the treatment of eczematous eruptions when located on the scalp or ears, that arsenic is always indicated. This, he states, has been the result of his experience, both in private and at the Hospital for Diseases of the Skin. The same remedy is required, whether the patient be old or young, but in some cases in young children, it may be desirable to combine the iodide of potassium with it.

## Medical Times & Gazette.

SATURDAY, JANUARY 23.

#### PROSTITUTION.

In two recent articles we called the attention of our readers to the subject of Prostitution. We asked our Professional brethren to consider whether something might not be done by them towards diminishing the evils which are being infused into the minds and bodies of the people through this large source of corruption; whether the legitimate influence which they exercise over society might not be turned to

good account in this respect. We will now endeavour to point out how the evil may best be encountered, and how most effectually stayed or diminished.

No remedy, it is certain, will act effectively upon this social malady which does not tell directly upon the causes which produce it. The roots of the poisoned tree must be destroyed, if the vigour of its growth is to be arrested. A knowledge of the causes, therefore, will indicate the proper remedial agent. Now, a calm investigation of the causes of Prostitution naturally leads the inquirer in this sense to the conclusion that the vice must be operated against through three different agencies—through the individual, through society, and through the civil power.

We will therefore consider how each of these forces may be brought to bear against prostitution; and what are the duties which appear to appertain especially to each of them in this respect. And firstly, as regards the individual, we may observe, that of the many causes of the vice, there is one pre-eminent in force and constant in action, and this is, the uncontrolled gratifying of his illicit passions by man at any cost. This is what has been well called, the "major force of prostitution." It is the head and front of the offence, *fons et origo mali*.

Its consideration brings home to the heart and mind of every thinking person the duty which devolves upon him of restraining by precept and example, and as far as his individual action reaches, those wild and uncultivated desires of mankind—this reckless profligacy of the age. Every one of us may here bear a part. Youth itself should be better instructed. There must indeed be something radically defective in a system of education which throws young men upon the world utterly unprepared to struggle with this fever of the passions, and which indeed completely ignores their existence. It should be remembered that these passions are necessary parts of man's perfect nature, and that when disciplined they bring great happiness upon him, but misery when left to rage uncontrolled. Youth is taught the beauty of virtue, and the deformity of vice in the abstract; but, as Mr. Acton truly asks, What sort of armour is this to shield him against the temptations of lust which surround his steps, and, syren-like, beckon him on to sin, when he comes forth into the world, his own guide and monitor? Those who propose a "physico-moral" instruction for youth will of course be met with the objection, that great difficulties surround its administration; but it is certain that by prudence and due care such difficulties may be overcome. At all events we may fairly try the experiment, it being manifest that our present system is, in this respect, a complete failure.

Who, again, is so well fitted as the Physician to explain the untruthfulness of the reasoning, so often urged by individuals in palliation of fornication, that the passion which leads to the act is implanted in him by nature, and that its gratification is, therefore, permissible and necessary? He will tell the bad reasoner that this illicit gratification of the passion, so far from assuaging, only whets the appetite for further excesses; and that every man, through the means of mental and bodily gymnastics, has in his own power the cure for inordinate excitement. What sin, indeed, might not find its justification in such argument as this? And on this head we must appeal to the conscience of those of our brethren who recommend to their patients, on particular occasions, the commission of the act as a remedial agent. Such advice is, in our opinion, wholly unjustifiable; and we are convinced that a full consideration of the subject will demonstrate the gravity of the error to every candid mind. If followed, its beneficial effects, in the sense inferred, are very problematical; but its evil consequences are great and certain. It aggravates prostitution. It initiates, authoritatively, the individual into

sin, perhaps leads him into the first step of the *facilis descensus*, which leads to the depths of degradation, moral and physical. And the woman, too,—of whom it makes a mere vessel fitted only for pollution, to be turned to use just as a brute material agent,—why is she to be sacrificed, soul and body, for the supposed temporary gain of another, and her moral existence totally ignored? How can any right-thinking man reconcile to his conscience the giving of advice which leads to such results as these?

Individuals estimate this vice much too lightly. Immense encouragement, again, is given to the practice of it through the light and easy manner in which men converse upon it in social life. The jesting language on the subject which falls from their seniors upon the ears of young men just entering into the world, naturally brings them to look upon this illicit traffic as one of the common and ordinary affairs of life, in which every gentleman may indulge. Such conversation paves the way to sinning for the uninitiated, and confirms those who are already engaged in the error. It is a direct encouragement of Prostitution, and as such should be met on all occasions with reprobation, and be scouted from decent life as dishonest and intolerable.

The study of the history of Prostitution has forced the conviction upon us, that the main battle against it must be fought out in the heart of man himself. Men cannot be dragooned into virtue by Government. Every individual must put his shoulder to the wheel, and not idle his time in belling upon Jupiter to interfere. So long as men let their passions rage uncurbed, so long will Prostitution spread its upas branches through the heart of society. The ill-regulated passions of the individual are the "major cause of Prostitution," and necessarily, therefore, their due regulation will be the major force that must operate in the diminishing of the evil. The great work of regeneration must be done in the breast of the individual; and there is not one of us who may not here labour with an assurance of reward.

Next let us consider what is the duty of society as regards Prostitution. We have before seen that society indirectly encourages the vice, through a negligence in the performance of some of its duties. It permits innumerable habitations to exist in this city where boys and girls are, from their earliest days, modelled and fashioned to a life of thieving and prostitution. Prostitution, under such conditions, becomes, for the female, a logical necessity. The penalty of her guilt lies at the door of society, which knowing, performs not, its duties. Society again does not give a fitting help to those of the female sex who live by the needle, and who are frequently driven to the crime under the pressure of want and misery. Nor does it visit with its heavy judgment the villany of the seducer, who is ever ready to entice and precipitate the unfortunate victim, so urged to sin, to her fall. Men have yet to learn the true import of the word Prostitution—the human misery involved in the term. Not until they have done so will seduction be branded as a crime, and the seducer expelled from society, as one would drive a slaveholder from his domestic hearth. Society, also, indirectly fosters Prostitution by preventing marriages; it has established certain artificial necessities as indispensable to married life, and has decreed that he who cannot attain unto them shall not marry. How long will men submit to this wicked slavery of fashion?

What part society then should take in this work is clearly enough shown from these facts. To use the words of Mr. Acton as a summary: "The most obvious checks upon the supply (of Prostitution) in the power of society are—a modification of the restraints now imposed upon lawful wedlock among the educated classes, and a graver treatment of seducers and deserters of women. The measures which the

State should adopt in the same direction are—the punishment of seducers; continued improvements in the dwellings of the poor, higher education of poor females, and larger encouragement of emigration."

Thirdly, we have to consider, what are the duties of the Civil Power, as guardians of the public morals, in face of Prostitution. This is a very important question, but one which, in our opinion, is capable of receiving a very definite answer. In the first place, we may observe, that any State-interference with Prostitution, any special regulating of the vice by the Government, such as is practised by so many of the Continental powers, is not for one moment to be thought of as applicable in this country. The free spirit of the people, their inborn love of personal liberty, and the moral sense of the country, are entirely opposed to such interference. Nor do we see anything to regret in the fact. External decency may, perhaps, be better served thereby; but the vice itself is left to work its evil ways in secret.

Whatever may be the result of State interference in lessening the physical evils which are associated with Prostitution, it is difficult to believe that even in those countries where this interference is carried out with all the rigour of an organized Bureaucracy it lessens the amount of the vice. In Paris, for example, there are about 4000 registered prostitutes; but those engaged in what M. Parent Duchatelet calls clandestine debauchery are estimated at about eight or ten times that number. Now clandestine debauchery, he tells us, is of far more importance than public prostitution; "through it innocence is perverted and corrupted, it braves and paralyses authority, and propagates with impunity the most fearful contagion and the highest immorality."—Duchatelet, vol. i. p. 471, 3rd ed. In Austria again, and in Rome, where the Government is even still more straightlaced—where the existence of Prostitution is utterly ignored, and the prostitute treated as a criminal—we find that an enormous amount of the vice lies festering beneath the surface. It is the tale of the whitened sepulchre all over again—the affecting a virtue without the having of it. What Mr. Wilde calls "the disgusting exhibitions witnessed in the capitals of Great Britain are not permitted by the Austrian force; but notwithstanding the apparent moral condition of the City after night-fall, which must at once strike a foreigner, I am much inclined to think that the public exhibition of vice is often a test of private morality; as instances pro and con, I might adduce the cities of Rome and Vienna on the one hand, and Dublin on the other." Of the godly city of Munich, also, where public women and tobacco-smokers are not permitted in the streets, Mr. Wilde records, that in the year 1838 the number of illegitimate children born in it exceeded the legitimate by 270. In Vienna the proportion is only a little less than one illegitimate to two legitimate children.

We shall on a future opportunity show that our Legislature has already very properly placed in the hand of the civil magistrate powers sufficient to enable him to repress all outrages against public decorum which may arise through Prostitution—that the magistrate, in fact, at this moment possesses greater powers than he cares to exert, through fear of touching unfairly the liberty of the subject—and that he will undoubtedly exercise his authority and power more efficaciously than he has hitherto done, if called upon so to do by the voice of public opinion.

#### THE WEEK.

An epidemic of influenza has for some time past been very prevalent in Paris. At the same time cases of croup have become far more frequent than usual, not a day passing without tracheotomy being performed once or twice at the Hô-

*pital des Enfants.* A very unfortunate accident recently occurred there to M. Guérant in practising this operation. Notwithstanding his well-known dexterity, he made the incision into the trachea much too small, so that the canula could not be introduced in repeated attempts. While he was endeavouring to enlarge the aperture the little patient expired.

Dr. Thomson has mentioned an interesting fact respecting the prevalence of catarrh in London. In his last report on the health of Marylebone he says that, "in the highest and best ventilated parts of the parish, colds are less frequent than in the lower and more densely populated districts. In Portland-town the proportion of bronchitis and catarrh to the whole sickness was 9 per cent. during November, and about 8 per cent. in December; while in Lisson-grove, the ratio was 17 per cent. in November, and 9 per cent. in December; in the neighbourhood of Welbeck-street the proportion was 25 per cent. in November, and in December 28 per cent."

We have received some further information upon the results of the Poor-law investigation in the case of Mr. Symes, of Bridgewater, to which we alluded in our Number of January 9. According to our present impressions that gentleman has been very hardly used, and the hardship of his case is not diminished by the alleged fact that some of his Medical colleagues, practising in the same town with himself, are among his persecutors. We are now informed that the Poor-law Board have forwarded to Mr. Symes a letter requesting him to resign his situation, but upon what grounds this request has been made we are unable to understand. As is usual in such cases, a candidate has already started for the expected vacancy, but we do not publish his name, as we hope that he will see the propriety of withdrawing from so disreputable a course as endeavouring to supplant a professional brother, who has been made the victim of unjust representations. The candidate in question is said to be a relative of another Medical gentleman, who distinguished himself in the late proceedings by his hostility to Mr. Symes. We understand that Mr. Symes has refused to resign, and that he demands a further investigation of his case, or a positive dismissal. Public opinion, we learn, is strongly in his favour; and we believe that he has the goodwill of nearly every Medical man in Bridgewater, besides the unanimous voice of the inhabitants, both rich and poor, in that town. As we have before stated, it seems to us that the charges made against him were of the most trumpery description, and such as could not have been sustained for a moment in any court of justice in the empire; and unless we receive more evidence than that which has already been published, we can find no reason for altering our opinion of the conduct of the Bridgewater Guardians, and of the very one-sided course taken by the Assistant Poor-law Commissioner.

Those who are acquainted with the weekly report of the "Rise and Decline of Disease in the Metropolis," prepared by the Association of Medical Officers of Health, and published by the Board of Health, will be surprised to hear that the members of the latter body have declined to continue the publication of the Report. The reason assigned for the sudden discontinuance of this valuable publication is the expense. We hope that public expostulation will be in time to stop this suicidal step. Almost the only thing the Board of Health has done of value in relation to the health of the metropolis is the publication of these laboriously compiled statistics of the actual state of disease in London. A weekly return of the occurrence of disease in

connexion with the meteorology of the period is very important, as it will probably prove to be a much more accurate means of ascertaining the relation between disease and climate than the registration of death. Death frequently occurs long subsequently to the action of the causes producing the fatal disease; hence the importance, in a sanitary point of view, of these weekly reports of the occurrence of disease. We cannot imagine a more thoughtless proceeding than calling into action a powerful organization for the purpose of effecting an acknowledged good, and at the moment when the good was about to be attained to crush the means by which it could be realized. It would have been better for the Medical Officers of Health to have depended on their own unaided efforts than have depended on such a broken reed as the Government support has turned out to be. If the tottering Board of Health expects to curry favour with the House of Commons by such economy as this, we think they will find themselves mistaken. They ought well to have considered the question of the publication of this report at the beginning. They knew what its expense would be, and if worth the money at first, it certainly is now, after each week's successive improvement in the variety and number of its details. On looking over these reports we feel that they are far from perfect; but imperfect as they are, there is not existing anywhere a body of information on the prevalent diseases in so large a community as that which they furnish. Had they been continued, then, and improved gradually, they would have formed a no less valuable contribution to the science of Vital Statistics than the Registrar-General's reports. Nothing could be a better commentary on the feebleness of the Board of Health and its managers than the fast-and-loose manner in which they have treated the Association of Medical Officers of Health in this subject. But we hope that something may yet be done to save us the almost national disgrace of not carrying out this valuable project. Every one is interested in a knowledge of the laws of health and disease, if not in the health of London; and we hope yet to hear that this publication, so necessary to the efficient action of the Medical Officers of Health, will be continued. If the Government refuses its aid, would it not be within the scope of the function of the Metropolitan Board of Works to assist the Officers of Health?

The Birmingham controversy is taking a more amicable turn. It is proposed as a means of settlement that Mr. West shall be appointed Surgeon to Queen's Hospital as well as Mr. Gamgee. The only difficulty which attends this plan, is the settlement of the point who is to be the Senior Surgeon. Forseeing this difficulty Mr. Gamgee has written to the Principal of the Queen's College proposing that the question should be settled "after full and impartial consideration of professional claims—scientific and practical—as considered by academical career, public positions held, original investigations conducted, and works published." He adds,—"Lest it should be thought that circumstances might in the proposed basis of arrangement for the senior position be at present unduly in my favour, I suggest that the point be left unsettled for six or twelve months, then to be decided by the Council of Queen's College or by arbiters appointed by it; such decision or arbitration to be final." We trust some such arrangement as this may put an end to this unfortunate affair.

The event of the week is the inaugural meeting of the New Sydenham Society, which took place on Monday. Dr. Williams was in the Chair, and the various resolutions constituting the Society, defining its objects, accepting the laws proposed by the Provisional Committee, appointing the officers, etc.,

were proposed and seconded by Dr. Watson, Dr. Hodgkin, Dr. Budd, Dr. Quain, Dr. Peacock, Dr. Gull, Dr. G. Johnson, Dr. Sieveking, Mr. Erichsen, Mr. Solly, Mr. S. Smith, Mr. Spencer Wells, etc. It appeared that 246 members had already joined the Society. From this fact, from the cordial feeling which prevailed at the meeting on Monday, and from the approval expressed in numerous letters from the provinces, we augur a brilliant career to the New Society. The list of officers will be found in another column.

A reply to Dr. Rigby's letter in our last number on the Ventilation and Mortality at the General Lying-in Hospital, will be found in another column from Mr. Robinson, a Member of the Committee. Dr. Odling's letter to the Committee has also been placed at our disposal, and we extract the following passages, which completely bear out the statements we made in our first notice of the subject:—

"In the following years it is, I believe, admitted by both parties that systematic ventilation was not practised:—

Years.	Deliveries.	Deaths.	Years.	Deliveries.	Deaths.
1837	197	3	From April, 1850....	157	0
1838	76	20	— 1851....	192	7
1839	197	7	— 1852....	216	8
1840	213	15	— 1853....	234	7
1841	119	16	— 1854....	272	10
			To May, 1855....	87	3
	802	61		1,158	30

"In the first five years we have 802 deliveries and 61 deaths, or 7·605 per cent.; in the second five years we have 1158 deliveries and 30 deaths, or 2·590 per cent.; and in the two periods taken together we have 1960 (802 + 1158) deliveries, and 91 (61 + 30) deaths, or 4·642 per cent.

"In the following years it is, I believe, admitted by both parties that systematic ventilation was efficiently practised:—

Years.	Deliveries.	Deaths.
From April, 1842	138	0
— 1844	179	0
— 1845	187	1
— 1846	221	0
— 1847	274	2
— 1848	320	1
— 1849	278	4
To April, 1850	64	0
	1,661	8

"In this period of seven years we have 1661 deliveries and 8 deaths, or 0·481 per cent.—a rate five times less than that of the period 1850-55, and  $9\frac{1}{2}$  times less than the mean of the two periods 1837-41 and 1850-55, in which systematic ventilation was not practised.

"It is, I believe, admitted by both parties that since May, 1855, the ventilation has not been carried on in such a definite manner as to allow of any results being deduced one way or the other.

"From April, 1842, to April, 1843, there were 219 deliveries and 19 deaths. You contend that this period should be included among the ventilation years, inasmuch as the ventilation arrangements were at that time completed. Dr. Rigby contends that this period should be included among the non-ventilation years, inasmuch as by the misuse of the apparatus, and the constant closure of the valves, all ventilation was effectually prevented. Seeing that your evidence is of a negative kind, and that Dr. Rigby's is of a positive kind—seeing, moreover, that his objections were made at the time of the occurrence, that he then made a written report to the governors on the subject, and that a circumstantial account of the difficulties he then encountered is on record in minutes of evidence before a committee of the House of Lords in 1844, I think that his views on this point should not altogether be disregarded; but even including this disputed period among the efficient ventilation years we arrive at the following result—that 1,880 (1,661 + 219) deliveries furnish 27 (8 + 19) deaths, or 1·436 per cent., whereas we have found in the non-ventilation years a death rate of 4·642 per cent.

"I fully believe with you in the influences of bad drainage, epidemic outbreak, and illegitimate pregnancy; nay, that with such conditions and good ventilation we may have a higher death rate than with imperfect ventilation in the absence of such conditions; but the point I wish respectfully to impress upon your attention—the point which you do not seem clearly to recognise—is that for seven years coincidentally with efficient ventilation, there was an extraordinary low death rate, and that the change from ventilation to non-ventilation was in a few months' time followed by an increase of mortality."

While we are wasting the sewage of London and polluting our river by it, it may be well to see how they manage matters in China. If the Chinese might imitate our "domestic arrangements" with advantage, we may certainly learn a lesson from their use of human ordure in agriculture, as described in the following extract from a letter of the *Times'* correspondent:—

"Stable-yard manure is scant. Nor is it much coveted. Human ordure is, in a Chinaman's opinion, the only perfect fertilizer. This is collected with the most oppressive care. In the cities and in the neighbourhood of cities enormous dark open earthenware pans offend the senses at every town, poisoning the air, inviting, and too often receiving, the contributions of the passers-by. The privilege of collection is sold for a large price, and the Cantonese have a proverb that a fortune every day passes in that form out of their gates. In the suburbs every cottage has its open earthenware cess-pool. In the country every house has its public latrine, ostentatiously placed with its open doorless entrance to the public path. In these temples the Chinese worship with a deliberate solemnity which savours of the ostentatious performance of a religious rite. The numbers and suffocating effluvia of these opposition manure-traps are to an Englishman a never-ceasing horror. They constitute his first and his last impression of the country. Like everything else in China, the favour awarded by law and custom to the collection of manure is used as a contrivance for extortion. This manure is sprinkled over the plant. It is too precious to be worked into the ground. The straw and the burnt halm of the cotton-plant are returned to the soil—that is all. The Chinese transplant every root of rice by hand, just as we should transplant young trees, and each has its little blessing of liquid manure as it is sown."

The competitive examination for Assistant-Surgeons in the East India Company's Service terminated last Saturday. There were thirty-seven candidates. Three of these gentlemen retired on the first day. Appointments have been obtained by fifteen. Dr. Walshe has examined in Medicine during the temporary retirement of Dr. Parkes. We will publish a copy of the questions and a list of the successful candidates in an early number.

## REVIEWS.

*De la Cause immédiate et du Traitement spécifique de la Phthisie Pulmonaire et des Maladies Tuberculeuses.* Par J. FRANCIS CHURCHILL, D.M.P. Pp. 255. Paris. 1858.

*On the Immediate Cause and the Specific Treatment of Pulmonary Phthisis and of Tuberculous Diseases.* By J. FRANCIS CHURCHILL.

DURING the last summer it may be recollected that a proposition was made to the Governors of the Brompton Hospital for Consumption by Dr. Churchill, to treat the patients of that institution by a secret remedy; but this proposition was, as we think very properly, declined. We pointed out at the time the impropriety of subjecting the patients of any charitable institution to any such ordeal; and it soon became known that the remedy employed was phosphorus in a low state of oxidation. It was then stated that Dr. Churchill had drawn up his cases and his conclusions in the form of a memoir, which he had presented to the Imperial Academy of

Medicine in Paris. This memoir constitutes the great bulk of the volume now before us.

Dr. Churchill explains that his reasons for publishing his memoir at this early period, before the Academy has made any report upon its merits, are the uncertainty which exists of any official decision being pronounced, owing to the present state of Medical science, the prejudices which exist on the subject of therapeutical questions, and the necessity of making known to the world the chief features of the proposed treatment, which has already encountered much opposition. It appears that Dr. Churchill, having experienced great difficulties in obtaining a trial of his plan in the Parisian hospitals, at last succeeded in gaining the co-operation of M. Bernard, of the Hospital of La Charité, who allowed some of his patients to be treated by the hypophosphites; but the course of the experiments was arrested by orders from the Administration which prohibited the further use of the remedy. Leaving Paris, Dr. Churchill visited London, and made the unsuccessful proposition to which we have before alluded, to the Hospital at Brompton. In his preface he blames not only the Governors of that Hospital for refusing to acquiesce in his views, but he also complains very bitterly of the English Medical press, although, as it appears to us, without any just grounds. We ourselves blamed Dr. Churchill for proposing to employ a *secret* remedy; but when the nature of his treatment was made known, we offered no objection to its employment, although it was mentioned that it was not new or original. However, Dr. Churchill being disgusted with England and the English Medical press, returned to Paris, and presented his memoir to the Academy, where it now remains, the members of the Academy having not yet offered any opinion upon the views which it advocates.

Dr. Churchill's theory of phthisis and of the tuberculous diathesis in general, is that it consists in a diminution in the economy of phosphorus in the oxygenable state, and that the specific remedy for this disease, therefore, consists in a preparation of phosphorus, which presents the double character of being immediately capable of absorption or assimilation, and which is, at the same time, at the lowest possible grade of oxidation. The hypophosphites of soda and lime are said to be the preparations which best fulfil these two conditions, this medication having an immediate action upon the tuberculous diathesis, properly so called, and causing the disappearance, with wonderful rapidity, of all the symptoms which result from it. When the morbid deposit, which is at once the special result and the pathological character of the dyscrasia, is recent; when the softening has only commenced, and is not proceeding too rapidly, the tubercles are absorbed, and disappear without leaving any nosological traces. When the deposit is of a more ancient date, and when the softening has somewhat advanced, it sometimes continues in spite of the treatment, and the result of the disease depends upon the anatomical state of the lesion and, above all, on its extent, and on the presence or absence of complications. The hypophosphites are said to have a double action upon the economy, for, on the one hand, they immediately augment the principle, whatever it may be, which constitutes nervous power; and, on the other, they are hæmatogenous agents of a marked character, and superior to all other medicines which are known to us.

The cases which have been submitted to this treatment were thirty-five in number; out of these, nine were completely cured, eleven experienced a great improvement, and fourteen died; one being still under treatment.

Whatever may be thought of these results, we can only remark that Dr. Churchill's reasonings are entirely hypothetical. Whether the treatment he proposes be really efficacious in the cure of tuberculous diseases time and experience can alone decide; and whatever prejudices may be supposed to exist against the trial of his remedy, we certainly entertain none, so long as it is not shrouded in the veil of secrecy, but fairly laid before the Profession.

*On Dislocations and Fractures.* By JOSEPH MACLISE, F.R.C.S. Fasciculus I. London: 1858.

THIS fasciculus contains four plates, in imperial folio, uniform with the Surgical Anatomy of the same author. Mr. MacLise proposes to proceed on a plan which must prove highly acceptable to the practical surgeon. He illustrates the mechanism of the healthy joints, in order to show by

contrast the derangements resulting from dislocations and fractures. He illustrates the various dislocations of each joint, not only with reference to the normal condition of the articular parts, but of the muscles which modify the dislocating force. The ligaments, as safeguards against dislocation, and the blood-vessels and nerves as involved in the accidents, are also illustrated.

It is really surprising that four large well-executed engravings can be supplied for the low price of five shillings, and it is equally clear that nothing but a large sale can make such a work at such a price remunerative either to author or publisher. Complaints are made of the dearth of Medical books, and often with justice; but in this case Mr. MacLise and Mr. Churchill have combined to produce a specimen of cheap Medical literature which is highly creditable to them both.

*Notes on the Cholera at Varna, in 1854, and more especially in Her Majesty's Ship "Agamemnon" in the Black Sea, between the 1st August, 1854, and 8th September, 1855.* By GEORGE MACKAY, M.D., late Surgeon of Her Majesty's Ships Bellephophon and Agamemnon. Pp. 43. Edinburgh: 1857.

It will be recollected that during the Crimean war, the ship Agamemnon was actively engaged in the Black Sea, in surveying the coasts and harbours, in aiding and directing the embarkation of troops and stores from Varna, in assisting the hostile invading army in the battle of the Alma, and afterwards taking part in the siege of Sebastopol. It will also be recollected that during that eventful period the horrors of war were aggravated by the outbreak of disease, which in the form of cholera first appeared at Varna, and afterwards raged in the ships composing the fleet of the allied squadrons. The present pamphlet contains a concise history of the origin and progress of the disease, from notes taken by Dr. Mackay while he was actively engaged as a Naval Surgeon, and it will be read with interest by all who desire to gain information on one of the most striking episodes of the operations in the Black Sea. Dr. Mackay is a contagionist, and he attributes the outbreak of the disease to infection from the French troops arriving from the south of France, where cholera had been raging previously to their embarkation. At page 610 of our last volume, there is a passage referring to the outbreak of Cholera in the Dobrudzsch, which confirms Dr. Mackay's opinion that the French troops carried the germs of the disease with them into that inhospitable region. "M. Baudens is certain that no cholera prevailed in the Dobrudzsch before the invasion of the French troops. Cases had already shown themselves in the Varna hospital, and these troops took the germs with them into only a too favourable soil." At p. 35 of the pamphlet before us, Dr. Mackay expresses his opinion that the outbreak in the Allied fleets at Baljik was due to the dispirited remnants of this expedition which had encamped on the heights overlooking Baljik. The treatment of this fatal malady appears to have been as unsuccessful in the ships of the allied powers as it was elsewhere, the greater part of the cases having terminated fatally. Dr. Mackay, however, is inclined to believe that calomel produces more beneficial effects than any other medicine. He gave it in scruple, ten grain, five grain, and two grain doses, sometimes alone, and sometimes combined with opiates. Another important measure was friction of the whole body, especially of the parts attacked by spasm, performed by strong muscular men, and continued until some degree of warmth was restored to the surface. These "Notes" will add to the high reputation Dr. Mackay has attained in his own service.

## PROGRESS OF MEDICAL SCIENCE.

### Selections from Foreign Journals.

#### ON INVOLUNTARY SEMINAL EMISSIONS.

By Dr. DICENTA.

Dr. Dicenta states, that for several years he has made this subject one of especial study. It is a well-known fact, he observes, that the bulk of persons liable to seminal emissions become the victims of fleeing quacks, while those of them

who resort to regular practitioners frequently meet with no correct appreciation of their case, or satisfactory treatment. The comparative rarity with which these affections come under the notice of individual practitioners, and the necessity of solid practical experience for the effectual management of a complaint exhibiting so many varieties and such obstinacy, sufficiently explain why this is the case. Sometimes the account given of themselves by these patients is very defective, and important points may be omitted unless they are questioned and examined by one who has full practical acquaintance with the matter. There is a general prejudice prevailing that these persons are hypochondriacs, and that their sufferings are mere creatures of the imagination; but the author, although commencing practice under the influence of this idea, has not found it confirmed. Patients suffering anxiously are frequent enough, but hypochondriacs, in the proper sense of the word, are seldom met with. The literature of the subject is barren, if we except a vast number of popular writings, which only feed the patient's anxiety. Individual opinions, derived from ill-understood or misinterpreted facts, take the place of a well-assured experience; and the disturbances of the functions of the organs of generation has become the arena for the exhibition of more adventurous proceedings than any other portion of human pathology. How it must fare with the therapeutics may be judged of from such a condition of the pathology of the organs in question—blind empiricism, barrenness, and uncertainty being the general characteristics.

**Physiological Preliminaries.**—It is well known that nocturnal involuntary emissions in many persons are physiological phenomena, analogous to the menstrual periods in women. A great number of unmarried men are liable to them in the midst of perfect health; but in others, though leading quite continent lives, they never make their appearance. The author has for a long period been engaged in investigations upon this subject. For the sake of comparison with the pathological conditions that result from such emissions, he here communicates the results derived from the questioning of 203 individuals, who have not sought medical assistance on account of these emissions, and whose statements can be implicitly relied upon. In the following account he understands by the word "rare," intervals of months in duration, by "not rare," intervals of three to four weeks, (the usually admitted normal frequency) by "frequent" intervals of eight to fourteen days, and by "very frequent," intervals of only three or four days. Distributing these persons according to their ages, we have the following results:—

a. From the age of 15 to 19, there were 44 persons questioned, and of these 13 had, and 31 had not, nocturnal emissions. Of the 13, in 4 the emissions were rare, in 5 not rare, and very frequent in 1; and in 4 there was constitutional reaction. b. From the age of 20 to 29 there were 96 individuals, 58 having and 38 not having the emissions. These were rare in 38, not rare in 16, and very frequent in 4—constitutional effects being observed in 22. c. Between the ages of 30 and 39, 43 persons, 24 with and 19 without emissions; these being rare in 16, not rare in 5, frequent in 1, and very frequent in 2, constitutional symptoms occurring in 5. d. From the age of 40 to 49, there were 13 individuals, 7 with and 6 without emissions, these being rare in 4, not rare in 3, and 3 with constitutional influence. e. Between 50 and 61, 7 persons, 3 having and 4 not having emissions, and these being rare in 2, and very frequent and with constitutional influence in 1.

Thus, among the 203 persons in question, there were 105 who exhibited nocturnal emissions and 98 who did not. Of these, in 34, or about a third, there had been symptoms of constitutional influence. These consisted in a feeling of debility, weakness in the legs, giddiness, pains in the head and in various parts, tremors, muscular cramps, nausea, sweating, defective vision, chronic exanthemata of the scrotum, etc. In 71 persons the emissions produced no effect upon the general system. Among the 105 persons the emissions were rare in 67, not rare in 29, frequent in 1, and very frequent in 8. The constitution was feeble in 6 persons, and normal in 197. Experience shows that the general constitutional condition exerts far less influence upon the exercise of the genital functions than does the condition of the genital organs themselves. Small, ill-developed genitals, a small penis covered with the prepuce, and a deficiency of pubic hair, generally betoken a slight degree of development of sexual life.

In 14 of these cases the genital organs were feebly developed,—the author regarding a pendulous scrotum as a frequent sign of such feebleness, although in other persons this is met with without any external sign of its existence. Of the 203 persons, 106 admitted that they had had recent cohabitation with varying frequency. In 64 of these the nocturnal emissions occurred (rare in 51, not rare in 8, frequent in 3, and very frequent in 2), and in 42 they did not occur. It results from these figures that involuntary nocturnal emissions occur oftener in those who resort to coition than is generally supposed. The ejaculations which take place in the unmarried state do not occur with sufficient regularity and frequency to displace involuntary emissions.

**Pathological observations.**—The distinguishing abnormal emissions from those which are consistent with health is not always easy; for what the indolent nature passes by unnoticed, the more sensitive may resort to Medical aid for. It is commonly stated, that when they occur but once within three or four weeks, they should be considered as a normal condition; but, according to the author's observation, a wider interval should be stated. This is not to be determined, indeed, by the interval alone, but by the condition of the health, and whether the emissions are preceded by dreams and erections, or are accompanied by regular coition.

The involuntary discharges may consist in either nocturnal or day emissions, and these last always constitute a pathological condition. From ample observation, the author is convinced that the emissions are frequently but the external sign of a congenital or hereditary diseased disposition of the ejaculatory apparatus. In different persons this abnormal disposition exists in very different degrees. Masturbation may be continued in some persons for years without any ill effects resulting, while in others a few months suffice to exhibit its ill consequences under various forms. In some persons night pollutions have continued so long and so abundantly, that we are surprised that they have not passed into day emissions, while in others they also rapidly become associated.

The pathological portion of this essay is founded upon 155 cases observed by the author, 131 of these occurring in the unmarried, 21 in the married, and 3 in widowers. The following is the distribution according to ages:—From 16 to 19, 16; from 20 to 29, 95; from 30 to 39, 32; and from 40 to 50, 12. The 28th year furnished the greatest number, viz. 16.

**Symptoms of Abnormal Emissions.** (a.) *Nocturnal Emissions.*

—These were met with in 140 of the 155 cases. In 100 of these the normal genital orgasm manifested itself in the form of dreams and erections, and in 61 there was no venereal orgasm.

(b.) *Day Emissions or Spermatorrhoea.*—These occurred in 33 instances from psychical or sexual excitement (as by the presence of women) of the genitals, generally with, but sometimes without, erections. In 25 they occurred, almost always without erections, during the passage of feces, especially when indurated. In 19 they succeeded the passage of urine. In 4 the discharges occurred without any exciting cause, and in 8 from different and varying causes. In 9 cases semen was unexpectedly found in the urine. In many cases the nocturnal emissions existed alone; but the day-emissions were usually accompanied by nocturnal ones, constituting an advanced degree of the latter affection. The different forms of day emission mentioned above were variously combined with each other and with the nocturnal emissions; and, indeed, any one form was seldom observed alone.

The diseased functional performances of the male sexual organs exerts a very manifold reflex action upon the general economy; and this action is much less dependent upon the nature and degree of the disturbance than upon certain innate dispositions, the vulnerability of the nervous system being the chief of these. The author exhibits the various local effects which abnormal seminal discharges exert upon the genito-urinary apparatus, and the general effects upon the various functions of the body, with great detail. For these we must refer the reader to the paper itself.

**Etiology.**—Abnormal seminal emissions are a disease of the young, occurring especially between the 20th and 21st year. The causes which give rise to it are very different, St. André enumerating as many as 21 occasional causes. In the author's view of the disease, two circumstances are necessary to its production, a peculiar innate disposition of the ejaculatory apparatus and occasional causes, which may be very different. Of these occasional causes onanism is the most frequent; but its influence differs much according to the

topical disposition of the ejaculatory apparatus. Various affections of the genito-urinary organs have been from time to time thought to play an important part in the production of this disease by Lallemand, St. André, Eisenmann, and others. In some cases these suppositions may be true, but the author's cases do not confirm this view. In his opinion it is a diseased condition, having its site in the muscular and contractile tissues of the ejaculatory apparatus. The proximate cause is an increased irritability of the reflex apparatus of the ejaculatory organs, and a diseased disposition of the muscular portion of these brought on by frequent repetition, whereby insignificant causes, which usually are without effect, give rise to ejaculation. The more this morbid disposition increases the less energetic does ejaculation become, as is well seen in spermatorrhœa. Among the 165 cases, masturbation was confessed to in 109, and in 69 there was a disposition to indulge in erotic mental representations.

*Treatment.*—This being a disease chronic and slow in its nature, we are to look for no rapid results from the employment of heroic remedies. A spontaneous recovery is far less to be reckoned upon than in the majority of other diseases. Our object is to restore the functional integrity of the affected part, and remove the disturbed conditions that have arisen. We have to deal with not only the various forms and degrees of the involuntary emissions, but also with the forms of incomplete exercise of the sexual function known by the name of *impotentia virilitis*. As in all other diseases our primary indication is to remove the cause. But, as a general rule, the occasional cause is no longer in operation; but years of mischievous influences have given rise to an anomalous condition, which is only susceptible of melioration by the gradual operation of well-adapted measures. For the realisation of this various means may be employed, less, indeed, depending upon the particular means in question than in their mode of employment, and in their judicious combination, succession, and continuance. To this end measures of a calming, composing, and strengthening character are those chiefly resorted to by the author. The constitutional symptoms are those which most readily yield to therapeutical agencies, while the local ones arising from the conditions of the genital organs are much more difficult to influence. Anomalous emissions, and their consequent evils, independently of their form and degree, present great differences in their amenability to treatment. Sometimes recovery takes place with surprising rapidity; but, as a general rule, their treatment is one of the most difficult tasks in practical medicine. The means to be employed are in part hygienic, in part medicinal, in part surgical, and in part psychical or moral. The author cannot agree with those who regard internal medicine in such cases as superfluous or useless. One favourable point for the treatment of this, as compared with other chronic diseases,—we know the source and origin of the mischief, and consequently the direction towards which therapeutical agencies should tend. On the other hand, for the attainment of a successful issue the most unwearied perseverance is demanded in bad cases from both patient and practitioner.—*Deutsche Klinik*, 1857, Nos. 2, 18, 19.

#### COMPLETE ABSENCE OF VAGINA AND UTERUS.

Dr. J. N. Warren related a remarkable instance of this to the Boston Medical Improvement Society. A woman, aged 25, was sent to him, supposed to have an occlusion of the vagina. She was well developed, 5 feet 2 or 3 inches in height, and had been married four years. She had never menstruated. On examination, there was found to be what at first seemed a very small vagina, that would only admit the little finger with much suffering, to which it imparted the sensation of passing through an old cicatrix. The breasts were well developed, the external organs were normal in appearance, and there was hair on the pubis. On further examination, during etherisation, the aperture corresponding to the vagina was found to lead to a cul de sac, and no urethra could be found. This aroused suspicion as to the nature of the case, and a catheter having been introduced into the aperture, urine at once flowed through it, showing that, in fact, the finger had only been passed into the dilated urethra. The finger having been re-introduced, and a finger of the other hand passed into the rectum, no traces of vagina or uterus could be found, while the forefinger of the hand in the rectum could be hooked, as it were, into the cul de sac of the peritonæum, and thus dragged down nearly to the anus. It was

evident that no surgical operation could be of any avail, but she was kept awhile in the hospital for observation during the next menstrual effort—this, according to the patient's account, occurring monthly, being announced by pains in the back lasting four or five days. In case any rudiment of the uterus existed, it was thought probable it would be manifested at that time. At the stated period the usual pains in the loins came on, but the most careful examination made by numerous physicians could not detect the slightest evidence of uterus, or of any pelvic or abdominal tumour, although the complete muscular relaxation from the ether allowed the finger to be forced high up into the pelvic cavity. The case is interesting from the fact that the patient presented perfect external development, accompanied with the usual sexual feelings. No vicarious discharge supplied the place of the menstrual secretion.—*Boston Journal*, vol. lvi. p. 297.

#### EXCERPTA MINORA.

*III Effect of Ferruginous Mineral Waters upon Lactation.*—M. Stanislas Martin observed at Chateaufort in Auvergne, that gallinaceous and ruminant animals were exceedingly fond of the ferruginous waters, but that these exerted the mischievous effect of drying up the milk of the cows. Wishing to see whether this effect extended to the human subject, he induced a young mother to make use of some of the strongest of these waters during several days; and the result was that if she had continued to drink them, all her milk would have disappeared. From this fact, among others, he cautions practitioners against prescribing ferruginous substances for nursing women, and when their employment seems clearly indicated.—*Bull. de Thérap.* Dec. p. 564.

*Shampooing in Sprain.*—This means of treating sprain, recently revived by M. Girard, is frequently had recourse to by M. Nélaton with complete and rapid success both in recent and old-standing sprain. A case recently presented itself, in which a man sprained his ankle while leaping. Cold water was immediately and continuously applied, but he remained unable to walk for three weeks, when he came under M. Nélaton's care. It having been ascertained to be an example of simple sprain, one of the *externes* slid his fingers under the feet, and having greased the two thumbs, pressed these with increasing force over the painful parts for about a quarter of an hour. In the course of the day the patient began to walk, and next day left the Hospital.—*Ibid.*

*Reduction of Hernia by Compression.*—In the employment of the taxis too much weight is sometimes laid upon the energy of the efforts and the violence exerted upon the herniated parts. A man, aged 54, was brought into M. Nélaton's wards, having a large irreducible inguinal hernia. Many attempts at reduction had been made without success, when M. Nélaton employed compression in the following manner: A strip of gutta-percha was placed over the upper part of the thighs, below the scrotum, and kept immovably in this position by means of bandages; a canvas bag filled with three or four pounds of sand was then applied over the tumour; this produced an uniform pressure, which was easily borne, and the mass diminished in size. The taxis was practised from time to time, until the whole was returned.—*Ibid.* p. 588.

*Oxide of Zinc in Profuse Sweating.*—Dr. Jackson has had repeated opportunity of confirming the utility of this substance in the nocturnal sweats of phthisis. He freely gave it whenever there was sweating enough to call for treatment without regard to the stage of the disease. Seven grains were generally (sometimes ten) given at bed-time, and if necessary the dose was repeated every few hours. He has also tried it with success in violent nocturnal sweating in intermittent fever, and in the sweating of acute rheumatism.—*Boston Journal*, vol. lvi. p. 294.

*Tartrate of Antimony in Colic.*—Dr. Puffer states, that having employed enemata of tartar emetic with good effect in several cases of rigid os uteri, he was induced to extend the same practice to a case of obstinate colic. About three grains were administered in eight ounces of sweetened water; and in about forty minutes the obstruction yielded without any apparent additional nausea or prostration, the patient rapidly recovering.—*Ibid.* vol. lvi. p. 326.

*Ergot of Rye in Phthisis.*—The Italian Practitioners continue to publish from time to time instances in which this substance has been used with great advantage, employed as recommended by Dr. Parola. Dr. Rossi now relates four

cases in which, after subduing inflammatory complications by antiphlogistics, he gave with success from 10 to 20 centigrammes per diem of the ethereal resinous extract of the ergot.

*Omodei's Annali*, vol. clxii. p. 216.

## FOREIGN CORRESPONDENCE.

### FRANCE.

PARIS, January 19, 1858.

In our sceptical age, we hardly take notice of assertions of practitioners concerning the therapeutical influence of new medicines. This may be right, but when the assertions come from respectable and intelligent men, we must at least take notice of what they say, and try the medicines. These considerations will explain our mentioning here the details of a paper of M. Ozanam, presented to the Académie des Sciences by Professor J. Cloquet. According to M. Ozanam the *Camomile* (*Anthemis nobilis*) has the power of stopping extensive suppurations, and, sometimes, preventing their appearance. The flowers of the plant are employed in an infusion of one-quarter to three-quarters of an ounce for one pound of water, to be drunk every day until the cure be complete. Besides, local applications of a strong infusion must be made on the suppurating surfaces. These applications are not essential, however, as without them the cure may be obtained.

M. Ozanam relates four cases, which certainly seem to prove the correctness of his views. The first is that of a man who had a very extensive erysipelatous inflammation of the face and head. Five abscesses had formed beneath the skin of the cranium, and almost the whole bony surface of the head was covered with pus. There was delirium and high fever. The infusion of *Camomile* was given, and after a few days, during which the suppuration went on increasing, it began to decrease, and after twenty days the patient was entirely cured. The other cases were as bad, if not worse than this one, and the patients were cured in from three to six weeks. If there is an increase of the suppuration in the beginning, in case that a very strong infusion has been given (one ounce a-day), the author says that the dose must be diminished.

A very interesting communication has been made to the Académie de Médecine, by M. Briquet, Physician of the *Charité* Hospital. The object of the paper is the nature and treatment of lead colic. What is the seat of the violent pain which then exists? Is it the digestive canal—the muscles of the abdomen—the diaphragm? Is the spinal cord affected, as Laennec and Barbier admitted? Is the pain purely neuralgic, as maintained by Andral and Grisolle? M. Briquet affirms, from researches made on forty-four patients, that the pain is in the muscles of the abdomen, sometimes in one, sometimes in many. He says also, that there is in some cases a real hyperæsthesia of the skin in the neighbourhood of the painful muscles. In some patients, however, the reverse exists: the skin is anæsthetic. He affirms that constipation has no influence whatever on the abdominal pain. He proposes in another paper to relate cases to prove that the application of galvanism to the painful muscles usually takes away the pain at once. We can assert that it is perfectly true that the pain may disappear immediately in cases of lead colic after one application of an electro-magnetic current.

M. Coulier has read a paper at the Académie de Médecine on some characters of blood-stains. He states that the presence of a colourless blood-corpuscle (white globule) may be of great importance, as it positively proves that the stain is from either blood or muco-pus. If the stain is red and of a uniform tint, and if besides fibrin be found with all its characters, then it can hardly be doubted that the stain is due to blood. M. Coulier, who is a very learned chemist and physiologist, seems, however, not to have been aware that Professor Jeffries Wyman, of Cambridge (U. S.) had already pointed out the value of the presence of colourless corpuscles in suspected blood-stains. Professor Wyman has insisted also on an interesting fact, which is that the red-corpuscles of the blood are much more easily altered by putrefaction and desiccation than the colourless or white corpuscles.

A young physiologist, M. Calliburçès, has announced to the Académie des Sciences that the application of heat on

the bowels and on the uterus of mammals produces in these organs very energetic movements. The contractions of the uterus may be powerful enough to expel one or two embryos.

Professor Bernard has shown to the Société de Biologie an interesting experiment. He applies galvanism to branches of nerves going to the sub-maxillary glands, and as a result, the secretion of saliva (as shown already by Ludwig) is increased, and, at the same time, the blood coming out by the veins of the gland, instead of being black as when the secretion is not active, is red. After the excitation has ceased the colour of the blood becomes black again.

Various means have been proposed against vomiting during pregnancy, in hysteria and other circumstances. Several French Physicians have lately tried with success in many cases some remedies either too neglected or quite new. During pregnancy vomiting has been stopped by the use of a potion of tincture of iodine (10 drops), iodide of potassium (10 grains), and 120 grammes (4 ounces) of water and syrup. This prescription has been employed by M. Becquerel. A physician of the south of France, M. Bacarisse, has made use of iodide of potassium alone, which he thinks to be more successful than tincture of iodine. Professor Buisson, of Montpellier, has tried three remedies: tincture of iodine with alcohol (a remedy much spoken of in Germany); iodide of potassium alone, and with tincture of iodine. With the first of these three medicines he has seen an increase of the vomiting; with the second, vomiting has hardly diminished; with the third it has completely ceased. He has made this trial three times. Dr. Martin Magron, of Paris, has employed successfully dry cupping on the spine, and in a case of obstinate hysterical vomiting he has succeeded at every fit in stopping the vomiting by this mode of treatment. In a case of paraplegia, with convulsive fits and vomiting, he has succeeded a great many times in stopping at the same time the vomiting and the fit, by cupping applied on the spine and slight bleeding.

## GENERAL CORRESPONDENCE.

### TREATMENT OF UTERINE HÆMORRHAGE.

[To the Editor of the Medical Times and Gazette.]

SIR,—Not having seen the letter from Dr. Pretty, which called forth Dr. Ramsbotham's reply in the last number of your Journal, I am, perhaps, somewhat rash in venturing to add my testimony to that of the latter gentleman, against the propriety of administering opiates in all cases of exhaustion from puerperal hæmorrhage. If I rightly understand the point at issue, Dr. Pretty attributed the recovery of his patient to the stimulating effect of the drug: as, therefore, I consider such practice, if universally adopted, likely to produce most pernicious results, I have selected two cases that occurred to me during the past year, strikingly showing how opium may check the tonic contraction of the uterus, both in instances of ante- and post-partum hæmorrhage.

Case 1.—Mrs. J. H., aged 22; primipara; of slight frame and highly excitable temperament, was taken in labour, at the full period, on February 1. I was sent for about 3 a.m., the pains having commenced an hour previously; they were then slight, but soon increased, and a succession of violent expulsive efforts brought the child into the world at five o'clock, the placenta following almost immediately. Having bandaged her firmly, I was about to leave the room, when hearing a slight moan, I returned to the bed side, and found she had fainted. The bandage was instantly loosened, but the uterus was felt firmly contracted. While, however, stimulants were being administered by the nurse and husband, the organ, under my hand, completely gave way, and a copious gush took place; alternate contractions and relaxations occurred at short intervals during the next half hour, although constant pressure was maintained, and a full dose of ergot got down. The right hand was then introduced, some few coagula removed, and the left hand being applied externally, a firmer contraction was brought about by the compression thus exercised upon the uterine parietes. Ice, which from the severity of the weather, was easily procured, had been employed during the whole time. She had now somewhat rallied

though still fearfully low, and after waiting another half hour to see if flooding returned, I gave her a dose of Battley's solution with sulphuric ether. Instead of this allaying nervous irritation, and further reviving her, relaxation again took place within a few minutes of the draught being swallowed, and she hovered between life and death until nearly 1 p.m., when, after vomiting freely, she became quiet, and from that time gradually improved.

Nothing in this case sufficed but the constant grasping of the womb by the hand; a task in which of course I had to be repeatedly relieved; but I have no doubt the relapse would not have occurred if the anodyne had been withheld until more permanent contraction had been insured.

Case 2.—Mrs. J. B., aged 41, in the eighth month of her ninth pregnancy, was seized with faintness and shivering about noon.

Nov. 11.—I saw her at 7 p.m., when she expressed herself as feeling better; she was then sitting up, and complained only of a little backache; there was no discharge, and on examination the os was found to be closed. The uterus felt externally of full size, and rather hard; pulse weak, 65.

From her own account one of her previous labours had commenced prematurely in a similar way, and I was at first inclined to believe that her faintness was only a nervous symptom of incipient parturition. I therefore made her keep the recumbent posture, and administered a full dose of liq. opii sedat. and sp. æth. s. co., waiting to see the effect.

I had not long to wait, for on returning to the room in about ten minutes, I found her unconscious and pulseless. The womb now appeared softer and larger. Stimulants freely administered were almost instantly rejected, as was also a dose of ergot. I immediately proceeded to dilate the os uteri, which up to this period was closed, and having at length reached the membranes, punctured them with a sharp pointed probe, and allowed a considerable quantity of coloured liquor amnii to escape; the uterus now contracted, and the pulse slowly returned. A second dose of ergot, after a short interval, was kept down, and regular action came on in about half an hour afterwards, the child being born (dead) a little before 10.

The same pain expelled the placenta, and with it coagula large enough to fill a full-sized hand basin.

She again fainted, but was soon restored, and had no bad symptom. There were no after pains.

In this case, it appears evident that the opium had a most injurious effect in relaxing uterine fibre, at a moment when its tonicity proved a natural safeguard to further loss of blood from partial placental separation. Had I not been influenced by the patient's own opinion, and by the absence of any urgent symptoms to call for the induction of premature labour, I should certainly have hesitated longer before I administered it.

I am, &c.

Peckham, Jan. 6, 1858. JOHN S. GRIFFITH, F.R.C.S.

### THE ANATOMY ACT.

[To the Editor of the *Medical Times and Gazette.*]

SIR,—As one who has some years' experience in the working of dissecting rooms, I beg to thank you for your judicious remarks on the faulty working of the Anatomy Act, in the last number of your Journal. The subject is one which requires discussion, and I should hope that in the present advanced state of popular education those prejudices which were so powerful thirty years ago, will not be found to exist, and that the public generally will perceive the necessity which exists, and which had better be met fairly at once, lest we should return to the ancient horrors of Hare and Burke. A young and active inspector might do much, but in addition I would suggest the following as regards the act. Let the Inspector of Anatomy change his title to that of "Inspector of Burials" (which would be less offensive to the pauper mind), and let it be his duty to superintend the burial of all bodies, the relatives of which are themselves unable to afford the necessary cost. Let a clause in the act make the delivery of all such bodies, whether in Poor-house, Hospital, or Prison, compulsory, and not as at present, at the caprice of the several boards of guardians, who do not scruple to incur great expense in doing that which they had much better leave undone. It may be objected that this is hard upon the friends and relatives; but private interests must give way to

public good, and by far the greater number of the paupers have no real relatives or friends to follow them, even if they were allowed to do so. I would suggest that the Inspector of Burials should give a formal receipt for each body, which, if drawn up in a proper form, would go far to tranquillize the scruples of any sorrowing relative.

The inspector would thus have a large supply of bodies, which should be distributed among the Schools in the proportion of the number of students; and should the supply more than equal the demand (as it would possibly in the summer), let the surplus be buried in the ordinary way. This plan would relieve the several parishes of all their burials, and would place the whole thing in the hands of a Government officer, who would effectually prevent such disgraceful occurrences as those at Newington. It would be necessary that the parishes should contribute towards the expenses; and this could be easily arranged, as the sum would probably be considerably less than the cost of the funerals under the present system. The inspector would, of course, employ undertakers at a contract price, and would be enabled to supply the schools at a price considerably lower than at the present time; and the undertakers being thus the servants of the inspector would not be able to raise their price capriciously as at the present time.

If the several Lecturers and Demonstrators of Anatomy would join and pull together something might be done; but as long as one or two hold aloof things will continue in their present miserable condition.

I am, &c.

DEMONSTRATOR.

January 17, 1858.

### MR. SYME AND HIS COLLEAGUES.

[To the Editor of the *Medical Times and Gazette.*]

SIR,—The brief review in your journal of the 9th instant, of the correspondence and statements regarding the teaching of Clinical Medicine in the University of Edinburgh, by Professor Laycock, has evoked from Professor Syme a letter, published in your columns last week, which in my mind claims notice on one or two important points referred to by him.

Professor Syme represents Dr. Laycock as the *protégé* of Dr. Simpson. As a member of the Edinburgh Town Council at the period of Dr. Laycock's appointment, and one who took a deep interest in the election, and part in his nomination, and well acquainted with the professional proceedings on the occasion, I trust you will deem this communication not irrelevant to the present bearings of the question in dispute, nor unworthy a place in your periodical. Mr. Syme has an undoubted right to express his strongest convictions with reference to Dr. Christison, as a man of "the strictest honour, and the most unimpeachable integrity;" but I hold that he is neither entitled nor justified in conveying inferentially (what he does not hesitate to do) the imputation that Dr. Laycock does not possess those good qualities which he has assigned to another, and far less in insinuating that the public sympathises with his allegations regarding the truth of Dr. Laycock's statements.

Dr. Simpson is thus implicated by his alleged "*protectorate*" of such a Physician, and the town council still more so (who are the legal patrons of Dr. Laycock's chair), by the appointment of such a Professor, and my attention has been called chiefly to the latter aspect of the question by Mr. Syme's letter. Now I most solemnly affirm I never heard, during the whole course of the canvass, that Dr. Simpson had either directly or indirectly interfered with a single elector. Dr. Laycock was elected most honourably to himself, for he was an utter stranger, without a personal friend at the Municipal Board to support him, and in the most independent manner by the town council, who considered him the most eligible candidate solely on the ground of his professional testimonials, and that in defiance of an open and unrelaxed opposition, up to the last hour of the election, by a section of the Professors, who had arranged that the successor to Dr. Alison should be chosen out of their number, to the exclusion of all foreign competition. It is much to be regretted that Dr. Laycock, after his induction into office, should not have received from his quondam opponents that right hand of fellowship which he had every title to claim

and expect, and which they, in duty and honour, were equally bound to have bestowed—a fellowship which, if conscientiously tendered, would, I need hardly add, have prevented a recurrence “of those constant and bitter feuds” which you have referred to so justly as being “not less discreditable to the parties, than injurious to the University.”

With regard to the other important point referred to by Mr. Syme in his letter, viz. that “Dr. Christison’s letter was returned to him, in order that he might correct an error pointed out by himself,” I have received the most undoubted authority (although I am not at present a municipal representative), from several members of the College Committee, to which the whole proceedings of the Professors on the subject of clinical teaching were remitted for consideration, for stating that Dr. Christison’s letter was withdrawn at his own request, and that the Committee permitted him to do so, *simpliciter* and unconditionally, without any reference to retraction or correction. The Committee, after hearing at two meetings the explanations of all the Professors, unanimously came to the conclusion that Dr. Laycock’s conduct was most honourable throughout. Indeed, several of the members referred to unreservedly expressed their opinion to me that Dr. Laycock was perfectly right, and they thought that he had been very badly used. In proof of this, the ungracious treatment which Dr. Laycock had received from a section of his colleagues was openly commented on at the public meeting of the Council, when the report of the Committee was brought up.

My sole object in entering into such an arena of unworthy contention, is simply to vindicate the Council, in electing Dr. Laycock, from having been actuated by any other motive than placing the right man in the right place. It is very gratifying to them to know that he has realized their fullest hopes, and that public opinion, after ample experience, has attested their decision by the confidence reposed in him as a scientific and most instructive lecturer, as well as a highly skilful practitioner. Hope delayed unquestionably maketh the heart sad, but there can be no doubt that the sharp edge of opposition directed against him must eventually, and at no distant date, be turned scatheless aside, by patience and perseverance on his part.

I am, &c.

JOHN KENTON, M.D. L.R.C.S.E. &c.

### VENTILATION AND MORTALITY AT THE GENERAL LYING-IN HOSPITAL.

[To the Editor of the Medical Times and Gazette.]

SIR,—Notwithstanding your suggestion that personal feeling would be better excluded from the discussion between Dr. Rigby and the Committee of the Lying-in Hospital, the staple of that gentleman’s letter, published in your last Number, consists chiefly of uncomplimentary remarks upon me individually, and I must therefore request you to give me space for a reply.

I am bound to admit that the calculations sent to Dr. Odling were mine, and that they were erroneous. I am sorry that they were so; but must deny the charge of “wantonly misleading” Dr. Odling, who was furnished not only with my deductions, but also with the data on which they were supposed to be founded. The chief source of error was the omission of the deaths in 1853 from the series; and this was patent on the face of the letter, but does not appear to have attracted Dr. Odling’s attention.

I was not a member of the Committee in 1842-3, and can know nothing of what then took place, except as I find it recorded on the minutes, of the “earnest written communications” alleged by Dr. Rigby to have been made by himself and Dr. Reid in the latter end of 1842 to the Committee, on the unhealthiness of the Hospital, or the systematic closing of the valves,—it was therefore impossible for me to notice them. The first notice of the subject entered upon the minutes is a resolution of the Committee, dated Feb. 18, 1843, calling upon Dr. Reid and the Medical staff for their opinion on the causes of the mortality then prevailing; and the letters from Dr. Reid, dated Feb. 27, 1843, and from the Medical staff on Feb. 26, were the official answers to the inquiry of the Committee. If any suspicion had then existed that the valves were systematically closed, it must have been noticed in these official communications, and the absence of such an

allegation, and the suggestion of other causes of the epidemic is irreconcilable with the account now given by Dr. Rigby.

Moreover, in the letter of Dr. Rigby, of the 14th Feb. 1843, it is broadly asserted that “the ventilation of the wards and the purity of the air were then satisfactory,” and the whole letter is an elaborate attempt to show that the Hospital was healthy, and that the deaths in that month were to be ascribed not to puerperal fever, but to the individual circumstances of the patients.

Dr. Rigby is now wholly silent as to the effect on the insalubrity of the Hospital produced in the beginning of March by the arrival in the following April of his two pupils from St. Bartholomew’s, on whose exertions he laid so much stress in his letter to Lord Galloway.

I do not see how these facts are to be reconciled with Dr. Rigby’s statement that the valves were kept constantly closed till April 1843, by the perversity of the matron and the nurses under her, and that the mortality ceased on the arrival and in consequence of the exertions of his two pupils in that month. And I cannot at present withdraw the charge that his statement is wholly unfounded.

As regards the mortality of 1855-6, no deaths took place in the months of January and February 1855, two in March, one in April, and none in May or June; and it is difficult to understand how the deaths which occurred in the following July and the eleven months following can be attributed to the previous contamination of the wards. However that may be, Dr. Rigby was not in any way interfered with by the Committee during that period, and his ill success in managing Dr. Reid’s ventilation might have taught him more forbearance for others, whose motives are probably as pure as his own, and who have not been more unsuccessful than himself.

Dr. Rigby’s version of the facts is indeed still more unfavourable than that set forth in the letter of the Committee. For according to him it was possible for the nurses so to mismanage the ventilation during a whole year, as to baffle the constant supervision of the Medical officer whose hobby the system was, and to cause the fearful mortality of 17 deaths out of 88 confinements; while that Medical officer could also so mismanage the ventilation during another year as by his own admission to render the number of deaths larger than it would otherwise have been. The utility however of any system bears an inverse proportion to its liability to mismanagement, and Dr. Reid’s system is, on Dr. Rigby’s own theory, peculiarly liable to objection on this ground.

Having carefully reconsidered the whole correspondence, I do not feel conscious of having had recourse to “little subtuges” or “unveracious quibbles,” or of attempting to “wantonly mislead” any one, but I deeply regret that Dr. Rigby’s constant use of similar language, whenever the slightest objection has been made to Dr. Reid’s system, has embittered the discussion of a subject which ought to have been considered in the interests of the patients alone, and apart from all personal feeling.

I am, &c.

67, Eaton-sq. Jan. 18, 1886.

AUGUSTIN ROBINSON.

### MALIGNANT MAMMARY TUMOURS.

[To the Editor of the Medical Times and Gazette.]

SIR,—In December, 1854, Mr. Spencer Wells showed me a tumour of the breast, which he had removed about three weeks before, and which was preserved in spirit and water. From this latter circumstance, all that I could say, after a prolonged examination, was, that it differed from any scirrhous tumours I had ever examined before. On March the 7th, 1857, I assisted at the autopsy, and made a most careful examination of the consecutive deposits. Any one knowing nothing further of the case than what Dr. Aitken has given in your Journal would imagine the sequence of events were these: a “glandular” tumour was removed from the breast; this was followed by “glandular” deposits under the skin and viscera. Indeed, no less an authority than Professor Bennett has been thus misled in a paper he has just published in the *Midland Quarterly Journal*, “On the Classification of Morbid Growths.” (a) Mr. Birkett has, on the other hand, thrown some doubts on the interpretation of facts, and I now enter

(a) Professor Bennett’s words are, “Aitken has recorded two well-observed instances, where, subsequent to the growth having recurred in the mamma, it appeared in the lungs, liver, and ovaria.”—Op. cit. p. 10.

my own protest, not only against Dr. Aitken's interpretation of the facts, but, what is more, against the facts themselves.

The true nature of this case was simply this:—A tumour, apparently innocent, was removed by Mr. Spencer Wells in Nov. 1854: six months after cancerous deposit took place in the part: this was followed by cancerous consecutive deposits under the skin and in the viscera. I have seen instances of medullary cancer supervening on epithelioma (Mr. Butcher has reported a whole series of such cases in the 22nd vol. of the *Dublin Quarterly Journal*). I have seen cancerous tumours engrafted on fibrous growths; I know of the same phenomenon succeeding cystic tumours. Although, therefore, I am ready to admit the interest of the case at issue, I must join with Mr. Birkett in "most strongly dissenting from the proposed classification of the case."

I am, &c.

J. ZACHARIAH LAURENCE.

30, Devonshire-st. Portland-pl. Jan. 16, 1858.

#### STUDENTS' BRANCH OF POOR-LAW MEDICAL REFORM ASSOCIATION.

[To the Editor of the Medical Times and Gazette.]

SIR,—We shall feel obliged by your allowing us, through the medium of your Journal, to inform the Students of the Metropolitan and Provincial Hospitals, and others interested in Poor-law Medical Reform, that since the General Meeting, held in St. Martin's Hall, petitions having received the signatures of nearly all the Medical Students in England were presented to Parliament at the close of last session.

The Treasurer's statement, as seen below, shows that he has a balance in hand of £21 14s. 10d. We have now, as far as practicable, carried out the resolutions of the General Meeting, and it remains with the Students to propose any further proceedings in the movement.

*Treasurer's Statement. — Receipts.* — London Hospital, £5 17s. 6d.; University College, £6 6s. 6d.; Guy's, £5; Bartholomew's, £5; King's, £5 10s.; St. George's, £4 10s.; St. Mary's, £4; Cork, £3 10s.; St. Thomas's, £3 3s.; Middlesex, £2 6s. 6d.; Westminster, £1 13s.; Charing Cross, £1 5s. Total: £48 1s. 6d.

*Expenditure.* — St. Martin's Hall, etc. £17 3s. 6d.; cab-hire, postage, etc. £3 9s. 4d.; printing, stationery, etc. £4 19s. 4d.; advertising, 14s. 6d. Total: £26 6s. 8d. Balance: £21 14s. 10d.

We are, &c.

MORELL MACKENZIE (London Hospital),

WILLIAM TILBURY FOX, M.B. (Univ. College),

Honorary Secretaries.

Jan. 18, 1858.

#### REPORTS OF SOCIETIES.

#### ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, JAN. 12, 1857.

Sir C. Locock, M.D., President, in the chair.

A paper, by Mr. HULKE, was then read,

#### ON SOME POINTS IN THE PATHOLOGY AND MORBID ANATOMY OF GLAUCOMA

The ophthalmoscopic examination of many cases of glaucoma, and the dissections of several eyes affected with this disease, have furnished the facts detailed in this paper. Two chief forms of glaucoma have been long recognised: they are the acute and chronic, but a large number of cases occupy an intermediate position. The symptoms of acute glaucoma have been often and well described, but the ophthalmoscopic signs are less widely known. They are: a dilated state of the retinal veins, often tortuous and turgid with blood; small ecchymoses scattered over the surface of the retina; occasionally small blood-clots in the vitreous humour; pulsation in the arteria centralis retinae; and an excavated state of the optic papilla. These last two signs were, the author believes, first noticed by Graefe, who insists upon their being pathognomonic of this disease. Although in acute glaucoma

the urgent symptoms often set in very suddenly, yet in a large number of cases the outbreak has been foreshadowed by a train of premonitory symptoms. These are: occasional dimness of sight, often towards evening, shooting pains in the eyeball, muscæ, and a gradual diminution of the field of vision. Graefe has drawn particular attention to this last point. The outbreak may be followed by a remission, only a temporary improvement, for fresh paroxysms will occur, and blindness inevitably result. In the advanced stages sclerotic staphylomata are apt to occur, mostly behind the insertions of the recti tendons. Chronic glaucoma differs from the acute chiefly by the insidiousness of its course, which is unmarked by those violent symptoms which characterize the outbreak of the acute form. It is quite as intractable as the acute form. The retinal veins are turgid, and the retina is sprinkled with hæmorrhagic spots, just as in the acute form. Sometimes in the same person one eye is attacked by acute, the other by chronic glaucoma. These facts favour the supposition that acute and chronic glaucoma are only different forms of the same disease. Graefe has called attention to a peculiar form of amaurosis, in which the optic papilla is excavated. This affection must be carefully distinguished from glaucoma, which may be done by observing that the globe is not tense, and the other signs of hyperæmia are also absent.

*Morbid anatomy of glaucoma.*—The small blood spots which are sprinkled over the inner surface of the retina are small spots of capillary hæmorrhage. This condition was first recognised in glaucoma, by actual dissection, by Mr. Bowman. The bleeding proceeds from the capillaries in the inner layers of the retina, and the blood either spreads laterally amongst the elementary structures of the retina, or, bursting through the hyaloid membrane, it forms small clots in the vitreous humour. The retinal capillaries are irregularly dilated and studded with small fusiform and globular enlargements—little aneurismal pouches. These dilatations do not occur on the large vessels. The pouches and the vessels communicating with them are usually crammed full with blood corpuscles. In the hæmorrhagic spots the retinal tissues are infiltrated with blood discs, which have escaped by the bursting of some of these little aneurismal pouches. Excepting the changes described above, the retinal capillaries have a healthy appearance, and do not present traces of fatty or atheromatous degeneration. The coats of the arteries are hypertrophied. The vitreous humour sometimes has a yellow tinge, which is derived from the colouring matter of the effused blood. It often contains blood discs and delicate fibrinous webs; and sometimes also small blood clots, which can be clearly seen with the unaided eye. The vitreous humour has a very remarkable degree of consistence, and does not quickly flow off when the eyeball is cut across. Viewed by transmitted light, the glaucomatous lens has a yellow tint like the vitreous humour, and which is probably acquired from the same source—viz. the colouring matter of the effused blood. The relations of the lens and the vitreous humour favour this supposition. In none of the dissections were any morbid changes found in the choroid, unless when staphylomata were present. Corresponding with the staphylomata, the choroid, retina, and sclerótica preserve their natural relations to one another, and are not separated by any effusions. The choroidal pigment is irregularly distributed; the tissues seem opened out. The subsequent changes in the retina and choroid, in the advanced stages of the disease, have an atrophic character. The dilated retinal capillaries and their contents have been found, dark and granular, in a state of fatty degeneration, and the contiguous parts of the retina participate in these changes. The symptoms, the ophthalmoscopic signs, and the structural changes which take place early in the disease, all point to a state of great vascular excitement in the retina, and a greatly increased internal pressure upon the walls of the globe. It is this pressure which causes the blindness in the early stage of the disease, and the fixed dilated pupil, for when the pressure is relieved by operation, sight and mobility of the pupil return.

Mr. BOWMAN thought that Mr. Hulke's paper afforded a remarkable instance of the very great advances which had been made within a few years in our knowledge of eye diseases, especially those which were deep-seated, and which, within a comparatively recent period, were extremely obscure, and for the most part very unsatisfactory in regard to treatment. With regard to the morbid anatomy of those affections they were indebted to the great advances made in micro-

scopic anatomy; but these would have been comparatively ineffectual in elucidating the nature of morbid changes in the deeper structures of the eye, had it not been for the opportunities of inspection immediately after the tissues had perished, which were afforded by the plan of treatment followed out by Mr. Critchett and himself within the last three years, of excising globes affected with chronic and excessive pain, more or less jeopardizing the other eye, and at any rate rendering the patient's existence very uncomfortable. The operation of excising an eye which was destroyed already and of no use in the economy, was now known to be an extremely simple proceeding, and one that could be adopted with perfect safety; it was done under chloroform, without pain; it was immediately followed by relief of the symptoms, and an artificial eye could be worn in a few days. He alluded to the operation as having given the means of examining the nature of the morbid changes in the deeper parts of the eye within an hour after removal, and enabling the microscopist to explore with great accuracy all the minute structures which were concerned, and to detail the several changes which they presented. Another circumstance of still greater importance was the invention of the ophthalmoscope, an instrument which was second to none in the exploration of the physical condition of disease in parts not open to ordinary sight. It had laid open all the parts of the eye, so long as they remained transparent, which were situated behind the pupil, and which before were absolutely closed to inspection. Formerly one might conjecture the condition of the eye behind the pupil, and sometimes by dilating the pupil with belladonna, get a dim insight into certain parts of the interior; but nothing was known of the structure of the retina during life from actual examination. With the ophthalmoscope everything near the axis of vision could be explored if the media were clear, and if they were not clear their opacity was thus disclosed. The Germans, by whom the instrument had been invented, were in advance of the English and French in its application; and no one had done more in the exploration, by its means, of the changes in the deeper parts of the eye than Professor Graefe of Berlin, to whose work on glaucoma the author had alluded. He had made out all the changes occurring in that remarkable disease. He had shown that there was a gradually increasing pressure within the eye contingent upon an increased afflux of blood into the vessels of the interior, and that with this there were several secondary changes. There was an enlargement of the veins on the surface of the eye in the same way as the veins of the abdomen were enlarged when the circulation through the liver was impeded. There was also an excavated state of what he should not call the "optic papilla," but the entrance of the optic nerve. Another remarkable condition alluded to by the author was the pulsation of the artery of the retina. Naturally that artery had no visible pulsation; but if the eye was pressed, even in a healthy person, for a certain time the pulsation might be rendered visible, the circulation being so impeded that the afflux of blood was shown at every jet. When this condition did not exist in glaucoma the slightest pressure would produce it, and Graefe regarded it as a pathognomonic sign of the disease. All these conditions characterised the disease in an unmistakeable manner, and pointed to the mode of treatment which Graefe had recommended. The practice at Moorfields had fully borne out the results which Graefe had announced at the recent Brussels Congress—namely, that by excising a portion of the iris in a particular way, in acute or chronic glaucoma (particularly the former) there was almost from the first a diminution of pressure, followed by an abatement of the symptoms, and an improvement of the vision, even when under great pressure it had been abolished for a time. Graefe had shown that the loss of vision in the condition of early glaucoma was not the result of any change primarily occurring in the retina, but of a pressure of the vessels, and that if such pressure was removed the retina regained its power, just as by compression within the head the brain might lose its functions for a time, and regain them when the pressure was removed. A rather interesting analogy was then shown by the ophthalmoscopic exploration of the eye in glaucoma—an analogy between the condition of the eye under such circumstances and the condition of the head in cases of internal pressure. The sclerotics, when tense, was just as effectual a source of counter-pressure upon the blood-vessels as the cranial walls could be; and he thought it probable that if the cranium had its con-

tents suddenly increased by an additional afflux of blood the arteries would, if they could be seen, be found to be like those of the retina, in a state of pulsation.

Mr. CRITCHETT said that the chief point of value in the paper was that the ophthalmoscope and microscope were seen to be beautifully illustrative and confirmatory of each other; and in that respect he thought Englishmen were in advance of the continent, however they might be behind the Germans in some other matters. He had no doubt that M. Graefe and others who had noticed certain points in reference to the appearances with the ophthalmoscope, would be interested in knowing that those points were illustrated and confirmed by microscopic observations. Where the globe had been the seat of serious disease, and was destroyed as an organ, remaining only as a source of irritation, and threatening by its sympathy with the other eye to implicate that organ also, the best practice was to remove the globe; and the introduction and carrying out of that principle had enabled the author to make a step in advance of the continent. All who had used the ophthalmoscope must have constantly felt the difficulty of interpreting the phenomena observed, which had been accordingly differently interpreted by different observers; but the mode of practice to which he had referred had led to a more accurate examination, and thus a most important advance had been made in reference to the scientific investigation of ophthalmic disease. The author had been one of the first to lead the way in that special form of investigation, and he looked forward with confident anticipations to the result.

Mr. HAYNES WALTON said that he and his colleagues had long recognised, and were among the first to point out, the sympathetic irritation of the eyeball, and the advantages to be derived from the removal of a globe thus in danger of affecting the other. Extirpation, he believed, was the plan usually adopted at Moorfields, but the same result might often be obtained by removing a portion of the eyeball, so that a stump of the eye remained, which was better than nothing, and more adapted for an artificial eye. It was said that the patient did not recover so quickly as after extirpation, and that he fully admitted. It was also alleged that troublesome bleeding might ensue; but if the operation was performed quickly, and the parts were covered with lint or cotton wool, and a slight compress applied, the hæmorrhage would almost always be checked and the recovery facilitated. He would, however, extirpate the eyeball when it was very much disorganised, where there had been a great deal of suffering in staphyloma, and where the sclerotics was much enlarged. The author's paper, he believed, rendered obsolete nearly everything previously written on glaucoma. He wished to bear testimony to the value of the ophthalmoscope, the application of which he found more and more useful and easy. A man applied to him a few days ago stating that he had become suddenly blind while at work. By the use of the ophthalmoscope he (Mr. Walton) at once discovered the effusion (between the choroid and the retina), which fully accounted for all the symptoms. Formerly the case would have proved very perplexing, and been probably attributed to cerebral derangement.

Mr. BOWMAN said that the system of extirpation was not always adopted at Moorfields. When the disease was confined to the front, the posterior part being comparatively healthy and not gorged with blood, a portion of the globe might be abscised; but if the disease was chiefly behind, and there was an enlarged condition of the vessels of the deeper tunics, excision he believed was best for the patient, and afforded the most rapid means of cure.

A paper by Dr. MAROET was then read,

#### ON THE ANALYSIS AND IMMEDIATE PRINCIPLES OF HUMAN EXCREMENTS IN DISEASE.

The object of this communication is—1. To describe an easy and very practical method of analysis to be applied to feces in the diseased condition. 2. To show that the method of analysis in question is essentially anatomical or mechanical, and as free as possible from chemical reactions. 3. To show that in three instances of disease where the bile was prevented from flowing into the duodenum, the feces yielded a quantity of crystallisable fatty acids (margaric and stearic acids), which immediate principles are known to be absent from healthy evacuations, except in certain cases depending on a peculiar diet. A few words may suffice for describing the analysis. The evacuations are exhausted with boiling

alcohol, and the solution strained through muslin. On cooling, a precipitate or deposit occurs in the fluid, which is separated from the mother liquor by filtration. This deposit, after it has been washed with boiling alcohol, is found in healthy cases to consist of stearate and margarate, or soaps of lime and magnesia, with or without earthy phosphates,—these compounds existing in the evacuations under examination in the form of immediate principles. The alcoholic washings or solution obtained from the deposit yielded, in cases of retention of bile, considerable quantities of free margaric and stearic acids. The clear original alcoholic extract being mixed with milk of lime, containing a considerable excess of water, is converted into muddy fluid, when a distinct precipitate will be noticed. After having collected this precipitate in a filter, washed it with water, and dried it on the water-bath, it is to be exhausted with a mixture of alcohol and ether. The clear extract thus obtained deposits on standing, in all healthy cases, impure crystals of excrete; a substance easily purified and prepared, perfectly colourless, by repeated crystallisations in alcohol and filtration through animal charcoal. I have previously described the characters of excretive in communications to the Royal Society, published in the *Philosophical Transactions* for 1856 and 1857. Diseased excrements do not always contain excrete, as it was absent in those cases referred to in the present communication, where it was searched for. The lime precipitate exhausted with alcohol and ether, is now to be mixed with water, and decomposed by means of hydrochloric acid; chloride of calcium is formed, and an insoluble substance remains floating in the liquid; this I have found very abundant in some diseased cases, and also in a few exceptional instances after a vegetable diet, it consisted of margaric and stearic acids mixed with a considerable proportion of oleic acid. Finally, by concentrating the filtrate from the lime precipitate on the water bath, and decomposing the residue with sulphuric acid, certain organic acids soluble in water are obtained, possessed of a very pungent odour, and whose properties have not yet been investigated; the castings of carnivorous animals yield in this stage of the analysis butyric acid, a substance not present in healthy human evacuations. It must be remembered that the animal body contains a number of organic acids forming known soluble salts with lime, and consequently the examination of the filtrate from the lime precipitate in diseased cases is not to be neglected. The above description, although necessarily most incomplete, gives a rough sketch of the processes I recommend for the analysis of fæces; it has been put to the test for the examination of a very great number of human evacuations, and found to yield constant results in health; it is, therefore, perfectly adapted for the investigation of the composition of diseased excrements. I now wish to draw the attention to the circumstance that chemical reagents have been used as seldom as possible in these analyses, in order to avoid the decomposition of immediate principles or of compounds, such as they exist in the body. Alcohol and ether, with and without the application of heat, are the principal means employed. It is not impossible, however, to determine immediate principles by chemical analysis; and a remarkable instance of the aid obtained from chemistry in these investigations, is the fact, that by the analysis of the mass deposited in the original alcoholic extract of fæces on cooling, I have been able to ascertain that it contains phosphoric acid, fatty acids, lime, and magnesia, exactly in such proportions as are required for the substances to combine in the form of earthy phosphates and earthy soaps. These compounds had, therefore, previously existed in the intestines in the form of immediate principles.—Dr. Marcet then gives the detail of three cases in which he carried out his examinations.

In answer to Mr. SPENCER WELLS,

Dr. MARCET said he did not think it possible to employ the fatty products of the fæces in the manufacture of candles, or make other industrial applications of the stearates, those products not being present to any extent in a healthy state except when a very large quantity of vegetable food had been taken.

**DEATHS OF OCTOGENARIANS.**—In the *Times* obituary of Tuesday there was a list of 12 elderly persons, recently "gathered to their fathers," whose united ages amounted to no less than 1,006 years, thus giving an average of 83½ years to each. The lowest age was 80, and the highest 90; three of the deceased persons were 64 years of age; three, 83; two, 82; one, 81; one, 80; one, 89; and one was 90.

## THE PATHOLOGICAL SOCIETY.

TUESDAY, JANUARY 19.

Dr. WATSON, President, in the chair.

AFTER some preliminary business,

Dr. PRAGOCK read for himself and Mr. HUTCHINSON a report on Mr. ORRÉ's specimen on

### SUPPOSED ABSCESS IN THE HEART.

The report stated that the abscess was an encysted one in the cavity of the pericardium, and did not involve the muscular substance of the organ. The pericardial layers were everywhere else adherent, evidently from the effects of a long past attack of inflammation. The abscess cyst was at the posterior part of the apex of the organ, and was about capable of containing a pigeon's egg. It would be manifestly erroneous to term it an abscess of the heart.

### Mr. CHRISTOPHER HEATH next showed a specimen of ANEURISM OF THE INNOMINATA OPENING INTO THE TRACHEA.

A man, aged 38, was admitted under Dr. Fincham's care, into the Westminster Hospital, in July, 1857, having been ill for nine or ten weeks with what he called "spasms." His pulse was then feeble and intermittent, and not perceptible at the right wrist; right arm colder than left, and somewhat numbed. Complained of pain in the cardiac region, shooting into the right arm, and was unable to lie flat in bed; he had also slight uneasiness on swallowing. There was a systolic murmur audible over the upper third of the sternum, in the carotids, and over the right infra-clavicular region, which was diagnosed to depend upon disease of the arch of the aorta or the innominata.

He was re-admitted on December 8, when the pulse was found to be imperceptible at the right wrist, and very nearly so at the left. There was a slight projection of the sternum, at a level with the second costal cartilage, and of the sternal half of the right clavicle, pressure producing an increase of pain in both those situations, which he described as shooting up the right side of the neck to the ear, and down the right arm. He was quite unable to sleep when lying down, and felt an obstruction to the passage of a large morsel of food at the top of the sternum. A loud bruit was heard over the sterno-clavicular articulation, and for some distance along the right carotid, and there was slight distension of the right external jugular vein.

On December 23 he first complained of a harsh, teasing cough, and on the 30th the expectoration was slightly stained with blood.

January 6.—Being then much exhausted with pain and want of sleep, he brought up about 3 p.m. a considerable quantity of florid blood, and this continued until he died, at 10 p.m., having expectorated about a porringer and a half full.

*Post-mortem.*—The tumour was found to be caused by an aneurism of the innominate artery pressing against, but not implicating, the bony structure of the clavicle and sternum. On opening the trachea a small ragged opening was found in its upper part, communicating with the aneurism. The arch of the aorta was dilated, and extensively diseased, and on opening it, it was found that fluid would pass into both the carotids, but into neither of the subclavian arteries, the right being obstructed by the clot in the aneurism, but the left obliterated close to the aorta, apparently by disease of long standing. It is remarkable that the pulse on the left, although weak, was so distinctly perceptible that no obstruction of the main artery on that side was suspected. The right pneumogastric and recurrent laryngeal nerves were stretched over the tumour caused by the aneurism.

Mr. HEATH also showed, for Dr. TODD, specimens from a case of

### CANCER OF THE SPINE.

A man, aged 50, came under Dr. Todd's care on December 28, 1857. Six weeks before had had great pain in the calf and part of the thigh of right limb, but did not suffer from cramp. After a fortnight the pain shifted to the left leg. At the end of the third week the pain ceased, but was replaced by a feeling of numbness in both legs, and loss of power in the left. About a fortnight before admission into the Hospital he began to pass his motions under him, and

soon afterwards was unable to expel his urine from the bladder, after which it was always drawn off by a catheter. On admission, there was complete loss of voluntary motion in both legs. Paralysis of the detrusor muscles, of the bladder, and of the sphincter ani. There was also loss of sensation in the feet, but considerable reflex action on the application of sudden cold. The muscles of both sides were completely relaxed, but there were occasional twitchings of the legs. No tenderness over the spine or deformity. Dr. Todd diagnosed rapid softening of the antero-lateral columns of the cord, more or less involving the posterior. On January 15 it became evident that the muscles of respiration were becoming involved, breathing being carried on almost solely by the diaphragm. He sunk gradually, and died on the 16th.

**Post-mortem.**—The spinal cord was found softened over a space extending from the second to the eighth dorsal vertebra, and the last dorsal vertebra was found hollowed out, as if in a carious condition. On opening the chest and abdomen a large mass of cancerous disease was found deposited opposite the last dorsal vertebra, and a similar one opposite the seventh and eighth dorsal. The liver also contained two large masses of cancerous matter replacing its proper structure, and the bronchial glands were infiltrated with the same matter. It is remarkable that the membranes were perfectly healthy, except in close proximity to the softening, and there were no masses of cancerous matter within the spinal canals. It is necessarily, therefore, a question whether the softening was the result of inflammation or of cancerous infiltration, on which point the microscopic appearances gave no reliable information. **Microscope.**—Softening of cord. Large cells containing oil globules of varying size. Large mother cells, containing nucleated cells, mixed with nerve fibres and vesicles. **Liver.**—Large compound cells; numerous small cells; no fibres.

Mr. NUNN exhibited the  
**ILIAC ARTERIES FROM A CASE OF TALIPES PARALYTICUS.**

The subject from which the specimen had been obtained was the same as that of which the dissected limb had been brought before the Society during the previous session by the late Mr. Lonsdale. The common iliac artery of the left was smaller than that of the right side in the proportion of 3 to 5, the external iliac being also smaller in the proportion of one to three. The left was the affected limb, and had been much wasted. The femur of the same limb was also exhibited, it being of interest as illustrating perfect union of an old fracture. The acetabulum was shallow and ill developed.

Mr. Wm. ADAMS remarked that the proportion of the diminution in size of the arteries on the paralysed side from the healthy one were pretty exactly those noted by previous observers. Very few facts had, however, been recorded in demonstration of the law.

(To be concluded.)

## MEDICAL NEWS.

**APOTHECARIES' HALL.**—Names of gentlemen who passed their examination in the Science and Practice of Medicine, and received Certificates to Practise, on Jan. 14:—

DEVAROUX, DANIEL, Bromyard, Hereford.  
FINCH, WILLIAM CORBIN, Salisbury.  
PRITCHETT, HENRY, York.

### DEATHS.

**BODDY.**—On the 10th inst., at Beaconsfield, Walter T. Boddy, M.D. St. And. 1860; M.R.C.S. Eng., and M.S.A. 1842. Aged 36.

**BROHIER.**—Jan. 7th, at Belvidere, St. Saviour, Jersey, Henry Brohier, M.D., Paris, 1821; B.A. 1820, aged 64; universally esteemed and regretted by all who knew him.

**HODGSON.**—On 18th inst., in Spital-square, Joseph Hodgson. Aged 57.

**LEGENDRE.**—M. Legendre, the author of several well-known works, and Physician to the Sainte-Eugénie Hospital, has just died at an early age, after a few days' illness.

**MOORE.**—Nov. 17th, Dr. Thomas Moore, Assistant-Surgeon Bengal Army, aged 39; massacred *en route* from Cuttack to Sumbulpore.

**NEW STDENHAM SOCIETY.**—The following is the list of officers elected at the inaugural meeting on Monday:—**President**—C. J. B. Williams, M.D., F.R.S., etc. **Vice-Presidents**—Sir Phillip Crampton, Bart., F.R.S.; Thomas Addison, M.D.; H. W. Acland, M.D. F.R.S. D.C.L., Oxford; William P. Alison, M.D. F.R.S.E.; Thomas Mayo, M.D. F.R.S., President of the Royal College of Physicians; J. Y. Simpson, M.D., Edinburgh; J. A. Symonds, M.D. F.R.S.E., Bristol; Thomas Watson, M.D.; W. Sands Cox, Esq., F.R.S., Birmingham; J. H. James, Esq., Exeter; James Paget, Esq., F.R.S.; Samuel Solly, Esq., F.R.S.; T. P. Teale, Esq., F.L.S., Leeds. **Council**—Robert Barnes, M.D.; William Brinton, M.D.; John J. Bristowe, M.D.; Andrew Clarke, M.D.; W. T. Gairdner, M.D., Edinburgh; C. Radcliffe Hall, M.D., Torquay; Thomas Inman, M.D., Liverpool; George Johnson, M.D.; Charles Murchison, M.D.; John W. Ogle, M.D.; Thomas B. Peacock, M.D.; Richard Quain, M.D.; W. S. Saunders, M.D.; William H. Stone, M.D.; Thomas H. Tanner, M.D.; John E. Erichsen, Esq.; John Hilton, Esq., F.R.S.; George M. Humphrey, Esq., Cambridge; William B. Page, Esq., Carlisle; H. Spencer Smith, Esq.; John S. Soden, Esq., Bath; Henry Thompson, Esq.; T. Jolliffe Tufnell, Esq., Dublin; T. Spencer Wells, Esq.; G. Hilario Barlow, M.D. **Secretary**—Jonathan Hutchinson, Esq. It will be observed that the list of officers is as yet incomplete. It is proposed to allow the Council to fill in the appointments left vacant, when the canvass for members shall be more advanced.

**EFFECTS OF FEAR.**—A Parisian Physician, during his visits made in a hired fly, had received a bottle of real Jamaica rum as a sample, but found, after returning home, that he had left it in the carriage. He went to the office, and informed the manager that he had left a virulent poison in one of the carriages, and desired him to prevent any of the coachmen from drinking it. Hardly had he got back when he was summoned in great haste to three of these worthies, who were suffering from the most horrible colic, and great was his difficulty in persuading them that they had only stolen some most excellent rum.

**THE DENTAL BODY.**—The President of the College of Dentists, as one of the Delegates to the Odontological Society, has retired from office; also the two gentlemen associated with him in that office, two of the Council, and two of the Secretaries, consequently the proposed method of amalgamation is virtually at an end. Still let us hope that a somewhat more acceptable mode of union may be thought of when some new blood is infused into the Council.

**ADVERTISING DENTISTS.**—On Wednesday last, Mr. Bowen May, of Russell-square, made an application to the magistrate for a summons or warrant against a person carrying on the business of a Dentist under a fictitious name, for obtaining money under false pretences. Mr. May stated that the person in question had entered into an agreement to supply a servant of a client of his (Mr. May) with a portion of a set of teeth, called an "upper," with gold plate for £10; that he obtained the money before the work was done, and then sent home the "piece" set in "dental alloy," a combination of silver, platinum, and zinc, which was totally valueless, as it could neither be worn nor sold—that part of the fraud was obtaining the money in a fictitious name, as he had picked up a small boy for the sake of his name, (that of an eminent Dentist,) and thus threw the public off their guard. Mr. Broughton, interposing, said that it was not a case for the Magistrates, but for the County Court. The advocate replied that if his worship would hear the witnesses he had in court, and who would establish the fact to demonstration, that this man had obtained the £10 upon the promise to supply goods to the value, and then had given an inferior article, he felt sure he would grant a summons. He would produce the person imposed on, and a scientific Dentist who would prove that the "piece" could not be worn, and was of no value. He further said, if his worship would grant a warrant that when the case was heard "The Times" and other influential journals would decline this man's advertisements, and thus a public benefit would ensue. His worship said that if such a case could be made out, the man might be given into custody and then he would adjudicate, but he should decline to issue a warrant. Mr. Bowen May left the court saying his client must adopt that mode and give the party into custody.

## VITAL STATISTICS OF LONDON.

## TO CORRESPONDENTS.

*Inquirer.*—Pirogoff's amputation at the ankle-joint was first described in this Journal in 1853. The full account, with drawings, is given in one number of the Surgical Essays of the Russian Surgeon.

*Dr. Cameron.*—Many thanks.

## THE ARTIFICIAL MEMBRANA TYMPANI.

Mr. Wilde has written to Mr. Toynbee to say that in his experience "it is not necessary to leave part of the aperture in the Membrana tympani unoccupied either by the cotton or India-rubber."

*Mr. James* had better consult some text-book on Anatomy and Physiology.

*Mr. Lisars.*—Thanks; the pamphlet shall be noticed.

*A Young Student.*—The term *ectrotic* is derived from *ἐκτρέφω*, I abort.

## BEGGING HOSPITALS.

## TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—This is one of the greatest disgraces to our country. Might not an attempt be made to raise "A General Hospital and Infirmary Rate," like any other government or local rate? A half-penny or penny in the pound would be amply sufficient. Such a rate would provide for the removal of patients from one part of the country to another, when change of air was ordered. It would likewise defray all travelling expenses, etc. "Leviathan Sanatoriums" could be established at several places at the sea-side and inland, having large surgical staffs, ambulances, carriages, invalid chairs, etc. etc., with proper staff of both male and female orderlies and nurses. In a few years the public health by such institutions would, I anticipate, become greatly improved, and the rate could then be discontinued altogether; as there would be sure to be a large surplus fund over and above after meeting every expense at the end of the year; which, when placed out at interest in the funds, would be sufficient to meet all expenses. We should not then hear of Begging Hospitals, and of private individuals leaving their fortunes to such noble institutions, and by so doing "disinheriting" their own relations. A farthing in the pound no one could grumble at; but at all events let us "agitate" for an Hospital rate.

## HARVEIAN SOCIETY.

## TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In your report of the late meeting of the Harveian Society in last Saturday's Journal, I am represented as having "related the case of a gentleman who was accustomed to periodical cupping, and who, by its practice, was made paraplegic." There is a slight mistake here: what I said on that occasion was this; that a gentleman had lately come under my own observation, who had been accustomed to repeated cupping without the sanction of any Medical man, and that I feared he had done himself mischief by thus acting on his own authority, for since then he has become the subject of repeated epileptic attacks. As your report stands at present, I am made unintentionally guilty of bad logic, as well as of imperfect pathological causation.

I am, &amp;c.

WILLIAM CAMPE.

Park-street, Grosvenor-square, Jan. 20, 1858.

*Dr. Todd's* Clinical Lecture on Hemiplegia will appear on the 6th of next month.

*Demonstrator.*—The Master of the Newington Workhouse has been committed for trial on the charge of disposing of bodies for dissection, but he has been admitted to bail.

*Dr. Bond's* letter arrived too late for insertion this week.

*B.* shall receive a note on the subject of the letter.

## DENTAL CARIES.

## TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In the last number of your Journal, page 72, is a letter from Mr. D. Mackenzie, addressed to Dr. J. Smith, in which the writer says, "Were he to refer to the Medical Times and Gazette of October 28, 1853, he would find that I recommended a wash . . . compounded to resemble an excess of healthy saliva."

I have searched for this wash through all the numbers of the Journal for October, 1855, and cannot find it. Would Mr. Mackenzie be so good as to put an accurate reference in your Notes to Correspondents in your forthcoming number? I am, &c.

GEORGE BULLEN.

Ipswich, Jan. 20, 1858.

## THE CORONER'S COURT.

## TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—At a Coroner's Inquest recently held by the Deputy-Coroner for the western division of the County of Middlesex, on the body of an aged female, whose clothes accidentally caught fire, and so burnt the old woman on the face, neck and arms, that she sunk under the effects of the burn, myself, her usual Medical attendant, and her attendant after the accident, was not summoned to the inquest. Upon inquiring whether the omission was accidental or intentional, I received from the Deputy-Coroner the following note:—

(Copy.)

"DEAR SIR,—In cases where the cause of death appears to be perfectly clear, it is not ordinarily our practice to summon Medical evidence at all. I will, however, put it to the jury in the course of the inquest, whether they require to have your evidence, and if so, I will send for you.

Truly yours,

GEO. S. BRENT.

Inquest Room, Jan. 11th, 1858."

If the conclusion of the Coroner is a just one, I should think, where the cause of death appeared perfectly clear, a Coroner's Inquest will in future be considered unnecessary.

At any rate, if the Coroner assumes the evidence of the Medical attendant in directing the jury—it strikes me such must be the case, and the county would, in such cases, save the unnecessary expenses attending Coroner's Inquests in many cases.

I am, &amp;c.

M. D.

West Drayton, near Uxbridge, Jan. 13, 1858."

## COMMUNICATIONS have been received from—

## APPOINTMENTS FOR THE WEEK.

Jan. 23. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's, 2 p.m. Charing Cross, 1 p.m.  
MEDICAL SOCIETY OF LONDON, 8 p.m.  
ROYAL INSTITUTION, 3 p.m.: Mr. Bloxam, "On the Chemistry of the Air."  
GUY'S PHYSICAL SOCIETY, 7 p.m.: Mr. Greenwood, "On Albuminuria."

## 25. Monday.

Operations at the Royal Free Hospital, 1 p.m.; Metropolitan Free Hospital, 2 p.m.; Orthopaedic Hospital, 3 p.m.  
ENTOMOLOGICAL SOCIETY, 8 p.m.  
JURIDICAL SOCIETY, 8 p.m.

## 26. Tuesday.

Operations at Guy's, 1 p.m. Westminster, 2 p.m.  
PATHOLOGICAL SOCIETY, 8 p.m.  
ROYAL MEDICAL AND CHIRURGICAL SOCIETY, 8½ p.m.: Mr. Haynes Walton, "On Vascular Tumour in the Orbit, successfully treated by injecting with Tannic Acid." Dr. Robert Lee, "On the Membrana Decidua which surrounds the Ovary in cases of Tubal Gestation."  
ZOOLOGICAL SOCIETY, 9 p.m.  
ROYAL INSTITUTION, 3 p.m.: Professor Huxley, "On Vegetable Life."

## 27. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m.: Orthopaedic Hospital, 3 p.m.

## 28. Thursday.

Operations at St. George's, 1 p.m.; Middlesex, 1½ p.m.; Central London Ophthalmic, 1 p.m.; London, 1½ p.m.  
ROYAL SOCIETY, 8½ p.m.  
ROYAL INSTITUTION, 3 p.m. Professor Tyndall, "On Heat."  
MEDICAL SOCIETY OF KING'S COLLEGE, 8 p.m.: Clinical Meeting.

## 29. Friday.

Operations at the Moorfields Ophthalmic, 10 a.m.; Westminster Ophthalmic, 1½ p.m.; Great Northern, 2½ p.m.  
ROYAL INSTITUTION, 8½ p.m.: W. K. Grove, Esq. Q.C., "On Molecular Impressions by Light and Electricity."

## EXPECTED OPERATIONS.

King's College Hospital.—The following operations are expected at this Hospital to-day (Saturday), at 2 o'clock:—  
Division of cicatrix following burn, by Mr. Ferguson.  
Westminster Hospital.—The following operations will take place at this Hospital on Tuesday next, at 2 o'clock:—  
Necrosis of femur; forcible extension of knee-joint; dilatation of two strictures of urethra: by Mr. Holt.

Just published, one vol., 8vo, cloth 6s.

**John Scott on the Treatment of DISEASES of the JOINTS and of ULCERS and CHRONIC INFLAMMATION.** A new Edition with an Introduction and a Chapter on the Constitutional Origin and Treatment of the Diseases of the Joints. By WILLIAM HENRY SMITH, F.R.C.S.

Longman and Co., Paternoster-row.

## New Equitable Life Assurance

COMPANY.—Offices, 449, Strand, Charing-cross.

### TRUSTEES.

G. H. Barlow, M.D., Union-street, Southwark.  
James Copland, M.D., F.R.S., 5, Old Burlington-street.  
Sir James Duke, Bart., Alderman, M.P. for the City of London.  
Sir Charles Hastings, M.D., D.C.L., Worcester.  
Richard Partridge, Esq., F.R.S., New-street, Spring-gardens.  
John Probert, Esq., 6, New Cavendish-street.

### DIRECTORS.

Chairman—George H. Barlow, M.D., 5, Union-street, Southwark, Physician to Guy's Hospital.

Deputy Chairman—John Weston, Esq., Hulme-House, Hampton-wick.  
George Chapman, Esq., 23, New-street, Spring Gardens.  
Richard Jebb, Esq., 9, Old-square, Lincoln's-inn.  
Thomas B. Jones, Esq., Holland-road, Brixton.  
J. C. W. Lever, M.D., 12, Wellington-street, Southwark, Obstetric Physician to Guy's Hospital.

W. J. Little, M.D., 34, Brook-street, Grosvenor square, Physician to the London Hospital.

Richard Partridge, Esq., F.R.S., 17, New-street, Spring Gardens, Surgeon to King's College Hospital.

Samuel Richards, M.D., 36, Bedford-square.

Robert Smith, Esq., 20, Endaleigh-street, Tavistock-square.

W. Tyler Smith, M.D., 7, Upper Grosvenor-street, Grosvenor-square, Obstetric Physician to St. Mary's Hospital.

J. Crace Stevens, Esq., 38, King-street, Covent-garden.

### CONSULTING PHYSICIANS.

Benjamin Guy Babington, M.D., F.R.S., 31, George-street, Hanover-sq.

James Copland, M.D., F.R.S., 5, Old Burlington-street.

### CONSULTING SURGEONS.

William Fergusson, Esq., F.R.S., 16, George-street, Hanover-square.

J. Banald Martin, Esq., F.R.S., 71, Grosvenor-street, Grosvenor-square.

### MEDICAL EXAMINERS.

F. J. Farre, M.D., F.I.S., 7, Montague-street, Russell-square, Physician to St. Bartholomew's Hospital.

Thomas H. Wakley, Esq., F.R.C.S., 7, Arlington-street, Piccadilly, Surgeon to the Royal Free Hospital.

By a small annual payment, Life Assurance secures the following provisions:—

1. Policies at death to husband, father, or son, so that widows and children are not left destitute.

2. Settlements secured in marriage contracts.

3. Endowments to children; so that funds are provided for apprenticeships, &c.

4. Security to creditors to provide against the death of their debtors.

5. Security to the debtors themselves; so that at death their estate or business is unincumbered by debt.

6. Capital to meet the loss entailed by the falling in of annuities or reversions.

7. Funds to meet renewals of leases at increased rents.

8. Sums of money payable to the assured themselves on attaining a certain age.

The attention of the Medical profession is called to the following scale of fees payable by the Company on business introduced by the medical attendant:—

Fee of £2 2s. for every assurance of £250 and upwards.

Fee of £1 1s. for every assurance of £100;

and, in addition, a commission of 10 per cent. on the premium of the first year, and five per cent. on subsequent payments.

Prospectuses and proposal forms may be obtained on application to

FREDERICK BIGG, Actuary and Secretary.

449, Strand, Charing-cross.

## Wines from South Africa.—Port,

SHERRY, etc., TWENTY SHILLINGS PER DOZEN. These

Wines, the produce of a British colony, which has escaped the vine disease (the vintage occurring in February may account for the same), are in consequence wholesome, and are warranted free from acidity and brandy, are admitted by Her Majesty's Customs at half-duty, hence the low prices.

A Pint Sample Bottle of each for twenty-four stamps, Bottles included. Packages allowed for when returned.

"We have taken the trouble to try Mr. Denman's wines, and have also submitted them to several of the clergy, and the opinion formed is that they are worthy of being patronized."—Clerical Journal, October 22, 1857.

EXCELSIOR BRANDY, Pale or Brown, 15s. per gallon, or 30s. per dozen. Terms—Cash. Country orders must contain a remittance.

Cheques to be crossed "Bank of London."

J. L. Denman, Wine and Spirit Importer, 65, Fenchurch-street. Counting-house entrance, first door on the left up Railway-place.

## Henry Simpson, 55, Strand, London,

Surgical Instrument Maker to the Royal Naval Hospitals and Royal

Army, &c. &c. Manufacturer of every description of Surgical Instruments, Trusses, Bandages, Artificial Limbs, Splints, Crutches, Enema

and other Syringes, &c. &c. Best quality (only), at the most moderate prices. Manufacturer of all kinds of Cutlery. Prize Medal, 1851.

### SPECIAL NOTICE.

To secure the advantage of this year's entry, Proposals must be lodged at the Head Office, or at any of the Society's Agencies, on or before 1st March.

### MUTUAL LIFE ASSURANCE.

THE WHOLE PROFITS DIVIDED AMONGST THE ASSURED.

## The Scottish Equitable Life Assurance Society.

INSTITUTED 1831.

Incorporated by special Act of Parliament.

The Fund accumulated from the Contributions of Members exceeds ONE MILLION STERLING.

The Annual Revenue exceeds ONE HUNDRED and SEVENTY-SIX THOUSAND POUNDS.

The amount of existing Assurances exceeds FOUR MILLIONS AND THREE QUARTERS.

The amount paid to the Representatives of Deceased Members is upwards of Nine Hundred Thousand Pounds, of which One Hundred and Twenty Thousand Pounds consisted of Bonus Additions.

A Division of Profits is made every Three Years, the next Division being at 1st March, 1859.

### HEAD OFFICE.

26, St. Andrew-square, Edinburgh.

ROBERT CHRISTIE, Manager.

WILLIAM FINLAY, Secretary.

LONDON OFFICE—26, POULTRY, E.C.

ARCHD. T. RITCHIE, Agent.

WESTERN LONDON OFFICE.

6a, James's-street, Westbourne-terrace, W.

CHARLES B. LEVER, Solicitor, Agent.

## S. Bowles, late Windsor & Co., Phial

and BOTTLE MERCHANTS, Dealers in Druggists' Sundries, &c., 37, Bartholomew-close, City. The cheapest house in London for every description of Medical Glass of the best quality.

Samples and Prices forwarded free on application.

## Surgical Instruments, and every Im-

plement necessary for Surgeons and Druggists, can be had (warranted best quality and moderate prices), retail as well as wholesale, from the Manufacturer, JAMES ARNOLD, 35, WEST SMITHFIELD, St. Bartholomew's Hospital, London.

Single Circular Truss, 2s. 6d.; double ditto, 5s.; on Salmon's Expired Patent, 4s. 6d.; double ditto, 9s.; on Coles's Expired Patent, 5s.; double ditto, 10s.; Cotton Net Suspensory Trusses, from 10d.; Elastic Stocking Net bandage, 4d. per yard; Case of Tooth Instruments, £1; Case of Cupping Instruments, £2 13s. 6d.; Case of Pocket Instruments, £1; Brass Enema Syringe, complete in mahogany case, 10s. and 12s.; Case of Dissecting Instruments, Ivory Handles, 15s.; best Bleeding Lancets, per dozen, 18s.

## Crosse and Blackwell, Purveyors to

Ordinary to Her Majesty, respectfully invite attention to their PICKLES, Sauces, Tart Fruits, and other table delicacies, the whole of which are prepared with the most scrupulous attention to wholesomeness and purity. The practice of colouring pickles and tart-fruits by artificial means has been discontinued, and the whole of their manufactures are so prepared that they are not allowed to come in contact with any deleterious ingredient. A few of the articles most highly recommended are, Pickles and Tart Fruits of every description, Royal Table Sauce, Essence of Shrimps, Soho Sauce, Essence of Anchovies, Jams, Jellies, Orange Marmalade, Anchovy and Bloaters Pastes, Strasbourg and other Potted Meats, and Cal's Foot Jellies of various kinds for table use. C. and B. are also sole agents for M. Soyer's Sauces, Relish, and Aromatic Mustard; and for Carstairs' Sir Robert Peel's Sauce, and Payne's Royal Osborne Sauce. The above may be obtained of most respectable Sauce Vendors throughout the United Kingdom; and Wholesale of

CROSSE and BLACKWELL, 21, Soho-square.

## Heigham Retreat, Unthanks - road,

NORWICH.—Private Asylum for the care and recovery of persons of the upper and middle classes suffering under mental derangement. The house is pleasantly situated, stands in extensive grounds, and is provided with every requisite comfort.

Visiting Physician—Dr. Copeman. Proprietors and Visiting Surgeons—Mr. Donald Dalrymple, Surrey-street; Mr. T. W. Crosse, St. Giles', Norwich. Resident Proprietor and Surgeon—Mr. H. Landor. Matron—Mrs. Landor.

Terms may be obtained from the Proprietors, and from Messrs. Bircham, Dalrymple, and Drake, 46, Parliament-street, London.

## Mr. Albert Smith's Mont Blanc, Naples,

Pompeii, and Vesuvius, every night (except Saturday) at 8, and Tuesday, Thursday, and Saturday afternoons, at 3. Places can be secured at the box-office, Egyptian-hall, daily, between 11 and 4, without any extra charge.

## Glamorganshire and Monmouthshire

INFIRMARY and DISPENSARY.—Wanted, for the above Institution, a legally-qualified HOUSE-SURGEON. Salary, £100 per annum, with furnished apartments in the house, coal, candles, and attendance. Testimonials and applications to be addressed to the Committee of the Glamorganshire and Monmouthshire Infirmary, care of Dr. Taylor, at the Infirmary, on or before the 2nd day of February.

Cardiff, January 6th, 1858.

NOTICE.

# West-end Dispensing Establishment.

In consequence of numerous errors which have occurred of late years through the carelessness of inexperienced Dispensers of Medicine, Messrs. CURTIS deem it expedient to assure the Profession and the Public that their method of transacting business precludes the probability of mistake, thus offering peculiar advantages for the Dispensing of Medicines, and fulfilling the best wishes and interests of the Profession and the Public.

# Messrs. Curtis continue to receive

the most satisfactory results from Medical Men in favour of

"PASMA,"

(Or, HEALING POWDER),

THE REMEDY FOR

EXCORIATIONS, BURNS, ULCERS, AND ERUPTIONS; ALSO, A PROPHYLACTIC OF ABRASIONS IN DELICATE, TENDER, AND IRRITABLE SKINS.

Messrs. CURTIS feel called upon to caution Medical Men against spurious imitations, and to inform them that the genuine is not a Metallic Preparation (nor a secret one), the Proprietors having informed the Profession its exact composition.

Messrs. CURTIS also invite the attention of Medical Men to their

NEW PHOSPHATE, or PULV. EBORIS PREPARATA, as prescribed by Dr. Stocker for *Blethete*, &c. &c. (Vide the *Lancet*, Dec. 19, 1857.)

Also to their

EXPRESSED JUICES, LIQUORS, MEDICINAL EXTRACTS, TINCTURES, &c. &c.

CURTIS & CO., Pharmaceutical and Dispensing Chemists, (Wholesale and Retail), 15, Crawford-street, London. Established 1820.

# Great Saving in the Purchase of Six

GROSS of NEW MEDICAL GLASS BOTTLES and PHIALS assorted to suit the convenience of Purchasers, at ISAACS & SON, Medical Glass Bottle Manufacturers.—London Warehouse, 6, Warren-street, Tottenham-court-road.

	s.	d.		s.	d.
6 and 8 oz., any shape, plain, or graduated ..	8	0	per gross.		
3 and 4 oz., ditto ..	7	6	do.		
1 oz. Moulded Phials ..	4	6	do.		
1 oz. ditto ..	5	6	do.		
1 1/2 oz. ditto ..	6	0	do.		
2 oz. ditto ..	7	0	do.		

No remittance required until the goods are received. Packages free. Delivered free within seven miles. Immediate attention to country orders. Post-office Orders payable to S. Isaacs and Son, at the Post-office, Tottenham-court-road, London. Bankers: Unity Bank.

# BROUGHAMS.

Kinder, M'Naught, and Smith, MANUFACTURERS, Warrington, beg respectfully to invite the attention of professional men to their improved Medical Broughams' as under:—

Width of Seat.	Weight.	Price.
3 ft. 5 in. ..	7 1/2 cwt. ..	85 Guineas.
3 ft. 6 in. ..	8 cwt. ..	95 Guineas.
3 ft. 7 in. ..	9 cwt. ..	100 Guineas.

The latter, including a segmental front, with seat for third person.

These Carriages are constructed, by the aid of machinery, of the best material, are of excellent workmanship, and particularly adapted to the wants of medical men, either in town or country. Drawings and other particulars forwarded on application.

# Recent Improvement by Mr. Jeffreys

In the RESPIRATOR. J. E. PERCIVAL respectfully invites the attention of the Profession to an important improvement in the Oral Respirator, which, having a maximum warming power of no less than 40°, can be instantaneously reduced, even without being displaced, to any of five grades down to a minimum of about 15°, and vice versa. So that, in an atmosphere varying between 30° and 55°, air may be respired of one steady temperature of about 70°, or lower if desired.

The Profession are doubtless aware that the name Respirator is being assumed for various defective imitations. The RESPIRATOR may be had of the principal Chemists and Surgical Instrument Makers in town and country. Wholesale Office, 25, Bucklersbury, City. J. E. Percival, Manager.

# Great Reduction in the Prices of New

MEDICAL GLASS BOTTLES and PHIALS, at the ISLINGTON GLASS BOTTLE WORKS, ISLINGTON-PLACE, PARK-ROAD. Warehouse—2, UPPER COPENHAGEN-STREET, BARNSBURY-ROAD, ISLINGTON, LONDON, N.

E. and H. HARRIS beg to submit the following prices for quantities of not less than 6 gross, assorted to suit the convenience of the purchaser.

	s.	d.		s.	d.
6 & 8 oz., any shape, plain or graduated ..	8	0	per gross.		
3 & 4 oz., do. ..	7	6	do.		
1 oz. white moulded phials ..	4	6	do.		
1 oz. do. ..	5	6	do.		
1 1/2 oz. do. ..	6	0	do.		
2 oz. do. ..	7	0	do.		

No remittance required until the goods are received. Packages free. Delivered free within 7 miles. Immediate attention to country orders. Post-office orders, made payable to E. and H. HARRIS, at the Chief Office, London.

Bankers: Union Bank of London.

# Williams and Son's Pure Glycerine

SOAP. Analysed by Dr. Hofmann, F.R.S., and Professor Redwood, Ph.D., strongly recommended by many eminent members of the Medical Profession, and favourably noticed by the following Medical Journals:—

THE LANCET.  
THE MEDICAL TIMES AND GAZETTE.  
THE BRITISH MEDICAL JOURNAL.  
THE MEDICAL CHRONICLE.  
EDINBURGH MEDICAL JOURNAL.  
THE DUBLIN HOSPITAL GAZETTE.

It is suited to all cases of delicate skin (whether arising from disease or otherwise), and is admirably adapted for nursery use. May be had of all respectable Chemists, Perfumers, &c.

SOAP-WORKS, CLERKENWELL, LONDON, E.C.

# PURE SPIRITS FOR THE FACULTY.

# S. V. R. 56 o.p., 17s. 6d. net Cash.

This quotation admits of neither credit nor discount, and is per gallon must be added for packages, to be allowed on their return.

HENRY BRETT and CO., Old Farnival's Distillery, Holborn.

# The Medicated Cod Liver Oils,

comprising

OLEUM MORRHUÆ CUM QUINA.

OLEUM MORRHUÆ CUM FERRI IODIDO.

&c. &c. &c.

# Liquor Pepsinæ.—A Convenient and

efficacious preparation by

SAVORY and MOORE, 143, New Bond-street.

# J. Bradshaw, late Shoolbred

and BRADSHAW, 34, JERMYN-STREET,

Begs to call attention to the various improvements in Patent

ELASTIC STOCKINGS, BELTS, KNEE-CAPS, SOCKS,

and Ladies' and Gentlemen's SPINE SUPPORTERS.

A new description of BELT, invaluable for prevention of Cholera, and the Cure of Rheumatism, Lumbago, &c.

N.B. Every description of INDIA-RUBBER BANDAGE, vulcanized on the newest principle.

Directions for measurement sent by post.

N.B. A liberal Discount to the Profession.

A female to attend on ladies.

# Wines from Cape of Good Hope.—

PORT, SHERRY, MARSALA, MADEIRA, BUCCELLAS, &c., all at 20s. per Dozen—pure and wholesome Wines, free from acidity and brandy, the produce of vineyards at the Cape of Good Hope, where the vines of Portugal and Spain are now being carefully cultivated, and have escaped the disease. Her Majesty's Government allows these Wines to be imported at half the duty, hence the low price of 20s. per dozen. Samples of any two qualities sent on receipt of twelve stamps.

"That wine, equal to any ever produced, can be made at the Cape, all the world has acknowledged."—Times, Nov. 8th, 1856.

The UNIVERSAL BRANDY, 15s. per Gallon, or 30s. per dozen.

W. and A. GILBEY, Wine Importers, Brandy Distillers, &c., 572, Oxford-street, London, W. Cheques to be crossed to our Bankers, the Bank of England.

# Kamala, a Powder obtained from the

Capsules of Rottlera Tinctoria. Recommended as a remedy for Tape-worm; medium dose, two drachms; see Medical Times and Gazette, May 2, and December 19, 1857.

ALLEN and HANBURY'S have a supply of the above-named Medicine, price to Members of the Profession, 1s. per ounce; if by post, 1s. 4d. Tincture of Kamala, dose two to three drachms, price 1s. per ounce.

London: Plough-court, Lombard-street, E.C.

# Pepsine.—M. Boudault begs to state

that he cannot be answerable for the purity and strength of any Preparation sold under his name unless obtained from his sole Agent, Mr. PETER SQUIRE, her Majesty's Chemist, 277, Oxford-street, London, to whom all applications respecting it must be addressed.

Second Edition of Boudault on "Pepsine," with Remarks by English Physicians Edited by W. S. SQUIRE, Ph.D., published by J. Churchill, London, may be also had of the Author, 277, Oxford-street, price Sixpence.

# James's Powder.—Physicians and

other Medical Practitioners having complained of the frequent use of Antimonial Powder, instead of the genuine "James's Powder" prescribed, have represented to Messrs. Newbery, that the price of the powder has greatly led to this fraudulent practice, and has also greatly prevented the more general use of the powder. Messrs. Newbery have therefore yielded to the suggestions of the Profession, and have reduced the price; and, to secure the use of the genuine medicine, recommend that the same should be prescribed as prepared by Messrs. Newbery, from the only copy of the process left by Dr. James in his own handwriting, thus, "Pulv. Jacobi Ver." (Newbery's.) The price for dispensing will henceforth be reduced from 21s. to 9s. an ounce. The genuine has the name, "F. Newbery, 45, St. Paul's, London," engraved on the Government Stamp.

## ORIGINAL LECTURES.

## A COURSE OF CLINICAL LECTURES

ON

## DISEASES OF THE KIDNEY.

By GEORGE JOHNSON, M.D. F.R.C.P.

Physician to King's College Hospital.

## LECTURE III.

I purpose to take as the subject of my lecture to-day two cases of acute Bright's disease, which you have had the opportunity of seeing in the Hospital.

Ann Barbrook, aged 50, was admitted into No. 7 Ward, on the 11th of March. She states that she is unmarried; a cook; of temperate habits; and that she was in the enjoyment of good health until a fortnight before her admission, when she caught cold, in consequence, as she believes, of kneeling much upon cold stones in the performance of her work. The legs soon began to swell, and were somewhat painful. The swelling then extended to the belly, and in some degree it affected the face. She also had pain in the back, and headache.

At the time of her admission the legs and thighs were very oedematous; there was evidence of liquid effusion into the abdomen, and the face was slightly swollen. In short, the case was one of general dropsy.

Now it is sometimes said that cardiac dropsy may be distinguished from renal by the fact that while the former begins in the feet and gradually passes upwards, the latter commences in the face, or, at any rate, affects the face simultaneously with the rest of the body. It is a fact that in cases of very sudden and acute renal dropsy, we often find that the face is swollen at the very commencement of the disease, but in not a few even acute cases, there is no swelling of the face until some days after the lower extremities have been dropsical; and in cases of chronic Bright's disease, the dropsical swelling very commonly begins in the feet and ankles; not unfrequently, too, it is confined to the lower extremities throughout the whole period of the disease. With reference, then, to the distinction between cardiac and renal dropsy you see that the mere fact of the dropsical swelling commencing in the lower extremities is of no value as a diagnostic sign. If we had relied upon this symptom alone we might have supposed that the case of our patient Barbrook was one of cardiac dropsy; we found, however, that the chest had, in every part, its natural resonance; the respiratory sounds were normal; so, also, were the sounds and the impulse of the heart. Here, then, we had evidence that there was no disease within the chest which would account for the dropsy. And, on the other hand, in the condition of the urine we had proof sufficient that the disease was of renal origin. The urine was scanty, pale, of low density, 1010, and contained a considerable amount of albumen. On microscopical examination, it was found to contain small wax-like fibrinous moulds of the kidney tubes (as represented in fig. 3, p. 2), without epithelium, pus, oil, or any of those appearances—to be described in some future lecture—which indicate disintegration and destruction of the secreting cells of the kidney.

In this case, then, as in the case of Herbert, to which I referred in my last lecture, the kidneys were in a *non-desquamative* condition. And as in the character of the urine there was nothing to suggest the previous existence of chronic disease of the kidney, so the history of the patient appeared to indicate a recent and acute attack. We therefore had good ground for hope that we might effect a cure.

Some of you will remember that I made this case the means of demonstrating to you the natural progress of acute renal dropsy when left almost entirely uninterfered with by art. Our patient when admitted had no urgent symptoms which called for active treatment. She had previously taken a sharp purgative, which for two or three days continued to keep the bowels freely open. I therefore ordered her to be kept in bed, on milk diet with beef-tea, and to be dry-cupped on the loins every night; but during the first fortnight of her stay in the hospital I gave her no medicine of any kind. As, however, it was probable she might think that without the use of drugs

we were neglecting an essential means of cure in so formidable a disease as dropsy, we prescribed a pill under the name of *mica panis*, to be taken three times a-day. You see, then, that the only part of the treatment which could be considered artificial was the dry-cupping. I did not feel justified in withholding this useful means of lessening the congestion of the kidney, and, of course, I was prepared at any time to resort to more active treatment by medicines if the necessity arose. Her progress, however, was entirely satisfactory. The urine soon became copious, and less albuminous, and at the same time the dropsical swelling diminished. During the first month of her stay in the hospital the average quantity of urine passed in the twenty-four hours was about eighty fluid ounces; one day it was 112 ounces, and once it was as much as 120 ounces in the twenty-four hours. With so great a flow of urine, the dropsy, of course, must quickly diminish and disappear.

What then is the cause of this copious diuresis, which you will find to occur during the favourable progress of every case of acute renal dropsy? In this case the abundant flow of urine was obviously not the result of diuretic medicine, for none was given. It was, if I may so say, a natural and spontaneous diuresis; and the following is, I believe, the explanation of the phenomenon. During the acute and congestive stage of the renal disease, the constituents of the urine, both solids and liquids, accumulate in the blood, and are then effused into the areolar tissue and the serous cavities. Now, urea is a most powerful diuretic, as is shown by the abundant micturition which follows the injection of this substance into the veins of a dog. As soon, then, as in a case of acute dropsy the congestion of the kidney subsides, and the freedom of its circulation is restored, the retained urea begins to exert its natural diuretic influence; and the resulting copious secretion of urine speedily withdraws the accumulated urinary solids and water from the blood; and then, by the quickened action of the absorbents, from the areolar tissue and serous cavities. In this way the dropsy is removed.

I am sure from my own experience that in the treatment of acute renal dropsy you gain nothing by giving diuretics. Bear in mind that a diuretic medicine, such as squills, or cantharides, or acetate of potash, acts by stimulating the kidney to an increased secretion, while the drug itself is being eliminated with the urine. If then you give such medicines during the early stage of acute renal dropsy, while the vessels of the kidney are gorged, and its circulation nearly stagnant, you impose upon that organ an extra amount of work, without in any degree increasing the eliminative powers of the gland; and if you attribute to the action of your medicine the diuresis which sooner or later follows its administration, you fall into the very common error of mistaking the natural course of a disease towards recovery for the curative operation of drugs.

Returning now to our patient, of whom, however, little more need be said, I find it noted that on the 23rd March she was ordered to take occasionally ten grains of compound colocynth pill, and that she afterwards took the following:—Tinct. ferri sesquichl. m.x., inf. quass. ʒi. ter die.

She continued steadily to improve, the dropsy disappeared from the body and the albumen from the urine, and she left the Hospital well on the 14th May. She might have gone out at an earlier period, but you know that we are extremely careful not to incur the risk of a relapse by allowing convalescents from acute renal disease to leave the Hospital while a trace of albumen remains in the urine.

In the case which I have just now related to you, recovery took place with but little aid from Medical treatment. I have now to ask your attention to the particulars of a patient whose urgent symptoms demanded something more than the usual routine of remedies.

S. M., aged 27, married, and the mother of one child, was admitted into No. 7 Ward on August 4, 1857. She states that for some time past she has been a sufferer from asthma, and that she has had thickness of the voice and hoarseness since the month of April in the present year. During the last three months she has lived badly, and has consequently been losing strength. About three weeks ago, after exposure to wet, she became very unwell, with feverish heat of the skin and throat, and on the following day dropsy commenced in the feet and quickly extended upwards. She then went under Medical treatment, and took purgative medicine, which acted very freely; in spite of this, however, the dropsy increased

the urine became very scanty, and the breathing extremely difficult.

When admitted into the Hospital on the 4th August there was much dropsical swelling of the legs and abdomen, and the face was pale and puffy, but the most urgent symptom was dyspnoea, which prevented her from lying down. She was breathing no less than sixty-two times in a minute, and the pulse was 128. Over the whole of both lungs, from base to apex, there were heard small and large-sized bubbling rhonchi, indicating the existence of much liquid in the air tubes. The urine was scanty, somewhat light-coloured, and contained as much albumen as, when coagulated, occupied one-half the volume of the urine. It deposited a rather copious cloudy sediment, which, on microscopical examination, was found to contain numerous small tube-casts entangling pus-cells. (Fig. 5, *a* and *b*.) Many pus-cells were also scattered free over the field of the microscope.

Fig. 5.

*a* and *b*. Small casts entangling pus-cells. *c*. Larger cast, containing pus-cells. *d*. Pus-cells acted on by acetic acid, and showing the compound nuclei. Magnified 200 diameters.

I beg you particularly to notice that these small pus-containing casts have a diameter which exactly corresponds with that of the free canal which exists within the epithelial lining of the tubes of the kidney, (see fig. 2. p. 1;) in this respect they resemble the small waxy casts which I have before shown you, (see fig. 3. p. 2.) These small casts then indicate that the Malpighian vessels are pouring an exudation into the free canal of the tubes, while the gland-cells which line the tubes remain unchanged. If the pus-casts had been of larger size, as represented at *c*, fig. 5, we should have inferred that the gland-cells of the kidney were being replaced by pus-cells, and our prognosis would have been most unfavourable. I have before alluded to the practical importance of observing the diameter of the various kinds of tube-casts, as a means of ascertaining whether the gland-cells of the kidney are being destroyed, and I shall hereafter give you additional illustrations of the same subject, but I wish now to confine your attention to the case which we have under our consideration.

We had then to deal with a patient whose lungs and kidneys were in a state of engorgement, and a question might arise as to which of these organs was the primary seat of disease. It not unfrequently happens that an albuminous condition of the urine and dropsy occur during the progress of acute bronchitis, especially when the bronchitis is grafted upon emphysema of the lung—was that the explanation of the albuminuria and dropsy in this case? We thought not, for two reasons. First, because we gathered from her history that although she had suffered in some degree from asthma, there had been no urgent difficulty of breathing until exposure to cold had induced a scanty secretion of urine and dropsy. And secondly, the pus-containing tube-casts indicated a more inflammatory condition of kidney than was likely to have been induced by simple congestion consequent on bronchitis. I have frequently examined urine rendered albuminous by a greatly impeded circulation through the heart and lungs, and have usually found in it only the small wax-like fibrinous

casts before mentioned, without either pus or epithelium in notable quantity. The probability therefore was that the kidneys were, in our patient, the primary seat of disease, and that the pulmonary engorgement and the bronchorrhoea were a part of the general dropsical tendency induced by the renal disease.

Then came the question of prognosis and treatment. As to the former, we knew from numerous examples of a similar form of disease that the condition of the kidney was essentially a curable one, but our fear was that the engorged and oedematous state of the lungs would be fatal before any treatment directed to the kidney could take effect. With dyspnoea so urgent, it seemed by no means improbable that a fatal result might occur within twenty-four hours. What then could be done to avert the tendency to death by apnoea?

Obviously it was of vital importance that through some channel or other water should quickly be eliminated from the system. To have given diuretics would have been something worse than useless. I have already told you that the dyspnoea and the dropsy had continued to increase in spite of very free purging before her admission. This circumstance in her history, together with the feebleness and rapidity of the pulse, appeared to forbid the use of elaterium as a hydragogue. I determined, therefore, to make a small incision in each leg, hoping that a copious and rapid drain of liquid from the wounds might in the course of a few hours so far relieve the lungs as to ward off the imminent danger of suffocation, and thus give time for the action of other remedies. I felt that I was justified in adopting this mode of treatment by my experience of the great and speedy relief from dyspnoea which often follows a drain of liquid from the legs in cases both of cardiac and renal dropsy. The remedies to which we resorted then were these: Pil. coloc. c. gr. x. om. n. Ether chloric. m. xx. mist. acacie ʒi. 4tis horis. Cupping to the extent of ʒiii. on the loins, and an incision half an inch long to be made through the skin a little above the outer ankle of each leg.

The relief afforded by these measures, and especially by that last mentioned, was greater than I had anticipated, or dared to hope. A large quantity of liquid rapidly drained from the legs, and in a few hours the dyspnoea was much lessened. The rapidity and the extent of the relief are best indicated by the frequency of the pulse and respiration. On the 4th—the day on which the incisions were made—the pulse was 128, resp. 62; on the 5th, p. 124, r. 54; 6th, p. 100, r. 32; 7th, p. 88, r. 34; 8th, p. 84, r. 32.

Meanwhile the urine became very copious, the albumen rapidly diminished, the dropsy disappeared, and the morbid lung-sounds ceased. On the 13th—nine days after her admission—the pulse was 80, respiration 26, the urine very abundant, with hardly a trace of albumen; the legs had nearly ceased to discharge, and the dropsy was almost gone. On the 18th the urine was reported free from albumen and tube-casts, and the dropsy quite gone. On the 20th we gave her a steel mixture as a tonic, and on the 5th September she left the Hospital well, except that the hoarseness before mentioned still remained, the result as we suspected of previous syphilitic disease of the larynx. We could get no distinct history of syphilis, but some large circular scars on the legs were suggestive of syphilitic rupia having left its indelible mark upon her.

## LECTURES

ON

## THE ANATOMY, INJURIES, AND DISEASES OF THE HEAD,

DELIVERED IN THE

Theatre of the Royal College of Surgeons of England.

By PRESCOTT HEWETT,

Professor of Anatomy and Surgery to the College.

## ON FRACTURES OF THE SKULL.

LECTURE I. (continued.)

AGAIN, we all of us know what it is to have to deal with a fidgetty, irritable patient, and we all of us know that patients in such a condition are much more liable to inflammatory action after wounds, than patients whose minds are calm and well regulated.

Some years back I had under my care a gentleman whose right hand was frightfully lacerated by the explosion of a powder-flask which he was holding. One of his ears was also all but cut off, and on the chest was a large effusion of blood, with extensive abrasion of the skin, caused by the body of the flask, which, striking him obliquely, had passed under the arm. The hand was saved, and, from first to last, every wound went on well; the pulse never rose five beats above the natural. What was the history of this? A healthy condition of body, and a well-regulated mind, which remained unruffled, and singularly calm throughout. Had it been otherwise, would the issue of the case have been such as it was?

Here, then, is another element, and a most important one, too, which we find altogether neglected in the statistics of Injuries of the Head, which we already possess.

But I think I have said enough to prove that statistics such as these cannot serve for our guidance in any question as to operative interference.

What, then, are we to do? Are we to place ourselves under the banner of one of the two great parties—the one recommending operative interference, the other condemning it? Are we to shelter ourselves under the great names arrayed under these banners? Names, it must be said, as great on one side as on the other. Such a course would be the easiest, no doubt, as far as we are concerned. But would it be the safest for our patient?

On the one hand, the use of the trephine is strongly recommended in all cases of compound fracture of the skull with depression and without symptoms, as such accidents give rise, more commonly than not, to intra-cranial suppuration. Here let us mark that it is nothing but the frequent occurrence of this form of suppuration which leads to the immediate operation; the trephine, in fact, is used to prevent the impending mischief. On the other hand, resting upon the numerous cases of a similar nature which have not been followed by suppuration, and which have recovered without any operation, it is argued that the trephine is evidently not always necessary, even in such cases as these; and hence that it ought never to be brought into use, unless symptoms indicative of serious mischief be present. Here there is no attempt made to anticipate the possible mischief; time enough to think of operating when there is no doubt as to the existence of the inflammation. Such are the two great doctrines into the value of which it now becomes our duty to inquire.

The truth will, I think, be found to lie in a middle course. Every case of compound fracture of the skull, with depression and without symptoms, must be judged of separately; and all the various circumstances connected with each individual case must be fairly taken into consideration. If this is done, the conclusion undoubtedly will be that there are among these cases some which demand the immediate use of the trephine, and others which assuredly do not.

Some short time back I was summoned to St. George's Hospital, in the dead of the night, to a young Irishman, who had, in a drunken brawl, received sundry cuts of a hatchet on various parts of the skull. With one exception, all these wounds proved to be superficial. Over the left brow, however, there was a wound, of an inch and a half in length, which led down to the bone: in the bone itself there was a deep cleft, with a narrow piece driven down. Situated immediately over the brow, as the injury was in this case, I did not think it necessary, as there were no cerebral symptoms, at once to resort to an operation. The wound was, therefore, strapped over, and the patient was purged and kept upon low diet for some days. Nothing of importance occurred to interrupt this man's recovery. The wound healed, and he was discharged from the Hospital without an ache or a pain.

Here I did not think of operating, as it appeared to me that the hatchet had acted in an oblique direction, and that the depressed piece of bone was a part of the superciliary ridge which had been chipped off. Had the injury not been in this particular spot, and even here had the hatchet struck the bone in a different direction, I should have acted differently.

There are then regions of the vault of the skull in which depressions of bone, even of a very marked character, do not demand the immediate use of the trephine—the frontal sinuses, the mastoid process, for instance. You will find many cases on record in which dissection has proved the existence of a very extensive fracture and depression of the outer wall of the frontal sinuses, without any injury whatso-

ever of the inner wall. But here let me remind you, however, that this can only occur after a certain period of life. Let us remember that in childhood and in early youth there are no frontal sinuses, and that consequently a deep in-driving of the bone must, at this particular period, involve the inner plate.

Again, when the depression of the bone is slight, and especially when such depression corresponds to the thicker parts of the injured bone, the trephine is, I think, not called for.

A woman, aged 51, was admitted into St. George's Hospital, under the care of Mr. Caesar Hawkins, in January, 1841, with a scalp-wound on the right side of the forehead, leading from the external angular process, two inches directly upwards. Corresponding to this wound the bone was laid bare, the breadth being about one-quarter of an inch; a fissure was easily seen in the course of the wound, and there was also a slight, but perceptible depression. The fracture did not appear to go beyond the wound at its upper part, but it was thought probable that it extended downwards, as there was some bleeding from the left ear, and from the nose; this bleeding was not, however, to any great extent. The wound was bruised, and the patient appeared to have lost a good deal of blood; she was in a state of collapse; had vomited before her admission, and again after it. She had been tossed into the air by a bull, and the fracture had, in all probability, been caused by the fall to the ground. She did not recollect anything of the accident, but was quite sensible when admitted ten minutes afterwards. It was determined that the trephine should not, under existing circumstances, be applied. The wound was, therefore, strapped at once. Inflammatory symptoms soon supervened, with great pain in the head, and intolerance of light. She was bled several times, and put upon calomel until the gums became sore; she then had antimony, and a blister was subsequently applied to the nape or the neck, as there was some drowsiness, accompanied by starting of the limbs. From these symptoms she gradually recovered, but complained of distressing noises in the head, as well as of some loss of sight. The wound, however, healed well, and the scar adhered firmly to the fracture. She remained in the Hospital for a month, and then went out; but she was readmitted in about a fortnight, for a recurrence of the pain in the head, and distressing noise in the ear. Leeches to the temples, blisters to the nape of the neck, and mercury, unto salivation, relieved these symptoms; and she again left the Hospital in about a month. Nothing further was heard of her.

In a large number of the cases of compound fracture with depression, and without symptoms, which have recovered without an operation, you will find that the depression of bone was but a slight one. Experience proves, then, that in the majority of these cases the bone need not be interfered with.

Hence the reason why many Surgeons of the present day who would trephine in other cases, strongly urge that in these cases of slight depression the trephine should not be used. It is true that in such cases we have no means of knowing the exact state of the inner plate, which may be splintered and driven down; but neither do we ever seek to know, in a fissure or in a comminuted fracture without depression, the exact state of the inner plate which here, too, may be injured. And then recollect that in a slight depression of the bone, the outer plate only may be driven in, with crushing of the diploë, and the inner plate remain unhurt.

In the case which I have just mentioned, the injury was followed by severe inflammatory symptoms, but such symptoms frequently arise even when the depressed bone is at once removed.

A lad, aged 15, was admitted into St. George's Hospital, under the care of Mr. Caesar Hawkins, in February, 1839, with a compound fracture of the skull, the broken bone corresponding to the middle part of the right brow, and about an inch above this region. The bone, which was driven in to some depth, measured an inch in length, and four lines in breadth. There were no cerebral symptoms whatsoever. The boy gave a clear account of the accident. In addition to the severe injury of the head, the right ankle was also dislocated. In a consultation with Sir Benjamin Brodie and the late Mr. Babington, it was decided that this was a case in which an operation ought to be resorted to. Mr. Hawkins proceeded at once to cut off a piece of the overhanging bone by means of Hey's saw, after which the depressed bone was ex-

removed. The dura-mater presented a perfectly healthy appearance. Cerebral symptoms, indicative of inflammation, soon made their appearance; repeated bleedings and antimony were had recourse to, and the lad ultimately recovered, notwithstanding some very severe symptoms connected with the injury of the ankle.

And now, let me bring before your notice some examples of compound fracture with extensive comminution and depression of the bone.

This is a class of cases in which it is admitted by most of our authorities of the present day that operative interference is necessary, and so I think it is in the majority of instances; but we shall find that, even here, some peculiar circumstance, attached to each individual case, may, and ought to make the surgeon modify his plan of treatment.

For the purpose which I have at present in view, I shall select some cases in which the general characters of the injury, both as to the situation, as to the nature and extent of the fracture and depression, and as to the symptoms, were as nearly as possible alike, and in which the surgeon was, nevertheless, led to differ widely in his practice.

A gentleman of Magdalene College, Cambridge, was one evening in the year 1839 brought to St. George's Hospital, with a severe compound fracture, occupying the right side of the frontal and temporal regions; the wound was a very large one, and, at the bottom of it, could be seen the bone extensively battered in, and broken into several fragments. He was perfectly collected, and gave a full account of the accident, which had been caused by his horse running away, and violently dashing his cabriolet against the iron railings in Park-lane. He was scarcely stunned, and, altogether unaware of the frightful nature of the injury he had sustained, insisted upon walking to the Hospital to have his head dressed. Finding that he had no symptoms whatsoever, he could hardly be brought to believe that his skull was broken, and much less that the fracture was one of a most dangerous nature. However, he ultimately consented to remain in the Hospital. Mr. Keate saw this gentleman shortly after the accident, and determined upon operating at once. The depressed fragments were so firmly jammed together that it was not without some difficulty that one of the smaller pieces of bone was got out: the opening thus made gave room for the elevator—several large pieces of bone extending under the temporal muscle were brought up to their proper level, and the looser pieces, some of which were large ones, were removed. A large gap was thus left in the bones at the upper and front part of the temporal fossa, but the dura-mater, thus extensively laid bare, did not appear to have been injured. The inflammatory symptoms which followed were successfully met by bleeding, purging, mercury and low diet. But when this gentleman began to go about the room, he for the first time discovered that he had lost the sight of the outer part of his right eye; he could no longer discern objects placed on his right side, but he could see them when they were brought directly opposite to him, and still better when they were carried over towards the left side. The movements of the eye-ball were as free as ever. In the course of time granulations sprang up, and this large wound scarred over; but the right eye still remained in the same condition when this gentleman left the Hospital. Finding that he was no longer capable of much mental exertion, he left College, and subsequently went out as a settler to one of our colonies. In the course of the years which have since elapsed, I have, now and then, heard of him—he was strong and well, but the right eye remained the same as it was when I last saw him.

With this case let us now contrast the following:—

A groom, aged 23, was admitted into St. George's Hospital under the care of Mr. Cutler, in April 1855, with a large scalp wound over the upper part of the left temporal region; the bone was laid bare to the extent of a shilling, but no fracture could be detected. The man having been kicked on the head by a horse a few minutes previously, had been stunned, but was already fast recovering his consciousness. Extensive diffuse cellular inflammation of the scalp supervened; incisions were made, and a large quantity of blood and pus let out. During the whole of this time this patient was somewhat incoherent in his manner, answered questions but imperfectly, and was very irritable; but at the end of a fortnight all these symptoms had subsided, and he was so far well, that he was allowed to go about the ward. On the 10th of May phagedæna suddenly made its appearance in the

wound, and soon exposed a large portion of the bones of the temporal fossa; and then was laid bare an extensive fracture, with depression, the existence of which had never even been suspected. It was at this time that my attention was called to the case by Mr. Phipps, the House-Surgeon, and on carefully examining the parts I found that a piece of bone, of an oval shape, about two inches in length, and more than an inch in width, was smashed in. The piece thus driven in was itself cracked into several fragments; the depression was extensive, more so, however, at the upper end and back part, where it was at the least the third of an inch in depth. The ridges of bone around were very rough and prominent. There was no pain about the head; in fact, the man felt perfectly well, and was exceedingly calm in his manner. The depressed bone was not interfered with. Granulations springing up from the surrounding parts soon covered over the exposed bone, the wound contracted and progressed rapidly, and the patient was again allowed to go about the ward. After some little time, however, he began to complain of some slight irritation and pain in the wound. This continued for a few days, and then, one morning, a piece of loose bone was detected imbedded in the granulations. The bone was removed without any difficulty. Measuring an inch in length, and the third of an inch in width, it included the whole thickness, and on its inner surface a groove for a large arterial branch was seen running across it. From this time the progress of the case was uninterrupted, and the patient was shortly afterwards discharged from the Hospital.

Here, then, are two cases presenting general characters strongly resembling each other; but how different was the treatment! If it was thought right at once to remove the depressed fragments in the first case, why was not this also done at once, so soon as the depression was detected, in the second case? Time was everything in these two cases. The different periods at which the fracture was detected became the guiding principle. In the first case, the depressed bone was not allowed to remain, for fear of the inflammatory symptoms which it would in all probability have given rise to. In the second, the depressed bone having been accidentally allowed to remain for a whole month without producing any mischief, it was thought that the parts had by this time got accustomed to the presence of the depressed bone, and that in consequence no harm would now arise from it.

Such were the reasons why the bone was removed in the first case, and not removed in the second.

But let me lay before you two other cases in which time again became the guiding principle in the different plans of treatment which were adopted.

A blacksmith, aged 23, was admitted into St. George's Hospital, under the care of Mr. Cutler, in April 1844, with a scalp wound, exposing a fracture. The wound, about an inch and a half in length, ran obliquely across the middle part of the coronal suture; the fracture itself was a little less in length, and half an inch in width. Of an oval shape, the fractured piece was broken, not only in its circumference, but also perpendicularly along its centre, where it was deeply driven in, so that the two fragments sloped towards each other. At the time of his admission this man was perfectly sensible and collected, and merely complained of pain, not of a severe character, at the crown and back part of the head: the pulse was 60, and labouring; the right eyelid drooped, but this, he said, existed before the accident: the right pupil acted somewhat sluggishly; the left was quite natural. The accident, which had happened the evening before, was caused by a quoit, which was pitched upon his head, a distance of about seventeen yards. He was knocked down, and stunned for some three minutes, but he soon rallied, and returned home, having lost a large quantity of blood from the wound. A Surgeon who saw him strapped the wound up, and sent him at once to bed. During the night, according to the wife's account, he was restless, so much so that he could hardly be kept in bed; there was great aching pain in the head, especially at the back part, and he rambled when asleep. He had been in the habit of drinking hard in former years, but of late had been very steady. After a consultation of the Surgeons, a small trephine was applied at the upper part of the fracture, and partly over the sound bone; the depressed portion was removed; the inner table was splintered, and several separate fragments were picked out; coagulated blood was found in the diploë, the dura mater did not appear to be injured. Inflammatory symptoms soon made their appearance; bleeding

and calomel were resorted to, notwithstanding which the symptoms went on increasing, and the patient died comatose on the second day after the operation. At the examination of the body, the outer surface of the dura mater, corresponding to the seat of the injury, was found covered with clots of blood and some lymph, but the membrane was throughout uninjured. The sub-arachnoid tissues at the upper part of the left hemisphere were extensively infiltrated with sero-purulent fluid. At the upper surface of the left hemisphere, the cerebral substance was bruised in one or two places; and towards the back part of the right hemisphere there was a small quantity of blood in the sub-arachnoid tissues. All the ventricles were enormously distended, and filled with a clear transparent serum; the lining membrane of these cavities was throughout rough, and as if sprinkled with white sand; the septum lucidum was exceedingly thin, but otherwise healthy. Old and firm adhesions existed in both pleural cavities; the lungs were gorged with blood, and red frothy serum. The muscular structure of the heart was very soft, and easily lacerated; the cavity of the left ventricle dilated, and its walls thin. The aortic valves were thickened, and two of them united. The liver, kidneys, and intestines were healthy. The spleen was small, and reduced to a semi-fluid pulp.

Again, contrast this case with the following:—

A stableman, aged 32, was admitted into St. George's Hospital, in June 1852, under the care of Mr. Tatum, with a suppurating scalp-wound, exposing a fracture. The wound was near the right frontal eminence; the broken piece, about an inch in length, was of an oval shape, and cracked not only in its circumference, but also perpendicularly down its centre, where it was depressed, the two fragments thus sloping towards each other; the depression was of no great depth. There was also another short line of fracture, which passed off to the right side; and here, too, there was a depression, which was of an angular shape. The man was perfectly sensible, and had no pain in the head so long as he kept quiet; the pupils acted naturally, the tongue was clean, but the pulse was remarkably slow, and it appeared as if the mouth was slightly drawn to one side. The following was the history of the case. Seven days before this patient's admission into the Hospital he had been kicked on the head by a horse, and knocked down. He was stunned for some minutes, but soon got up again; and he went to a Surgeon, who strapped the wound, and told him to go at once to some Hospital, as he was very seriously hurt. This he did not do, but went home, and kept his bed for five days, purging himself, and living low. He then tried to resume his work, but could not, on account of pain and giddiness in the head, and the profuse discharge from the wound. At a consultation of the Surgeons it was decided that no operation should be resorted to in this case, as the depression had already existed so many days without producing any marked cerebral symptoms. The man was kept in bed, purged, and put upon low diet. After some eleven or twelve days he was perfectly free from all headache, and felt as well as he had ever done. He was then allowed to go about the ward. At the end of nearly a month the wound had all but scarred over, a small piece at the top being the only part which was suppurating. At this period, being perfectly well, and without an ache or a pain, this patient was sent home, the Hospital being then overcrowded; and, as he was not heard of afterwards, it was concluded that all had gone well with him.

Here, then, are two more cases, as alike as possible in their general characters, in which time again became everything,—the different periods at which the fractures were seen being the guiding principle as to the difference of treatment.

Where we should operate, then, at once, if we saw the patient immediately after the accident, we ought in a precisely similar case not to operate, if we only saw the patient several days after the injury, provided the depressed bone had during that period given rise to no symptoms indicative of intracranial irritation and inflammation.

THE Director-General of the Medical Department has issued orders for several Staff-surgeons to proceed at once to Yarmouth, in order to make the necessary preparations for the reception of the invalid troops who are now on their passage home from India.

## ORIGINAL COMMUNICATIONS.

### EXPERIMENTS AND OBSERVATIONS ON THE ACTION AND SOUNDS OF THE HEART.

By GEORGE B. HALFORD, M.D.

Lecturer on Anatomy, Grosvenor-place School of Medicine, &c.

"Ut motum cordis soli Deo cognitum fuisse, pene opinaber." Such were Harvey's words when speaking of the heart's action. So rapid were its movements, that further on he says, "Ita ut modo hinc systolen, illinc diastolen; modo e contra; modo varios, modo confusos fieri motus, nec existimarem cernere. Unde animas mihi fluctuabat; nec quid vel ipse statuerem, vel aliis crederem, habebam."

I make the foregoing quotations from the writings of a great observer and thinker, in order to show that once or twice looking at the heart will not suffice for comprehending or even recording what is seen. Hence partly, no doubt, the many varied statements we have of what takes place during the action of this organ, added to the strange fact, that all experimenters hitherto, that is, so far as I am acquainted with their writings, have first removed the pericardium and its contained fluid (so indispensable to the heart's perfect action), and then made their observations; and even this applies to those made by Cruveilhier on a case of ectopia of the heart, for the organ was destitute of pericardium, had no support, but by its own gravity made its fixed point where in the natural heart there is most movement, viz. at its connexion with the aorta and pulmonary artery. He seems to have forgotten, in his laudable anxiety to portray nature, that what he was beholding was a *lusus nature*, not destined, because not perfected by the Almighty, for more than a few hours' fruitless and irregular struggles, which, however, were hit off, and handed down as a fac-simile of the heart's normal action. I doubt not for one moment the accuracy of M. Cruveilhier's observations; but they referred to an imperfect, and not to a perfect machine.

In bringing before the Profession the results of my own investigations, I confess they are far from perfect; they are, however, an honest record of observations frequently made, with a constant anxiety to exclude all sources of error; for no subject in physiology has perhaps been more besmeared with the cobwebs of fancy than that which is now engaging our attention.

In the *Lancet*, Feb. 8, 1834, is to be found a most ingenious paper by Mr. Bryan, "On the precise nature of the Movements of the Heart." It is purely theoretical, Mr. Bryan never having seen the heart act until he witnessed some of my experiments in 1856. I shall extract his concluding remarks with diagram, rather than clothe his ideas in my own less simple language.

After considering what must be the physical state of hollow bodies alternately distended by and contracting upon a fluid, he says: "From what has been advanced, I have been led to believe that the heart moves as exemplified in the following diagram:—

Let fig. 1 represent the heart; *a*, ventricles; *bb*, auricles contained in the pericardium, *c*; suppose the ventricles to have arrived at their extreme distension; the instant contraction

FIG. 1.

commences the auricular valves are closed by the blood; but no important alteration to the size or form of the ventricles takes place until the pressure of the blood contained in their cavities becomes greater than that in the arteries, when the basilar portions sink towards the apex, as from the line below *b* (on the right) to the dotted line below *t*, occasioning partial, or perhaps total, obliteration of their cavities. While this depression of the base of the ventricles is taking place, the auricles *bb* swell into the space *ii* receded from; thus rendering it unnecessary for the pericardium, and conse-

quently the parts in contact with it, to close in upon the contracted ventricles. During the diastole of the ventricles, the reverse of this movement takes place, *i. e.* the bases of the ventricles rise into the spaces *i*, from which the auricles withdrew."

When we shall have proceeded further upon our inquiry, I think we shall find that, with some little modification and extension, the above will represent the theory of the heart's action.

The following observations, Nos. 1—9, were made by me in 1855, with the assistance and in the presence of Mr. Waters, Lecturer on Anatomy, Liverpool; Mr. Webster, House-Surgeon to the Infirmary, and Mr. Friar, now of the H.E.I.C.'s service. We examined the heart's action most attentively for hours, evening after evening, and I have repeated the observations since then at least twenty times. The subjects of the experiments were large dogs, and the proceedings as follow: chloroform was first administered to produce insensibility, then the trachea divided, and the nozzle of a bellows inserted into the lower portion, and artificial respiration maintained; the anterior portion of the thorax, *viz.* sternum, cartilages of ribs, and part of the ribs themselves, according to the depth of the thorax, removed or turned upwards. In this process it was necessary occasionally to drop some chloroform into the valve of the bellows, otherwise the animal became conscious, and disturbed the operators. In this manner the heart was kept acting for a long period, often so long as to make me and others tired of observing, and the animal was destroyed forthwith; at other times, however, the heart soon ceased acting, and constantly, if the chloroform was given too rapidly, it ceased suddenly, and, on opening the thorax, was found distended. Only in one case, that of a rabbit, have I ever succeeded in making a single fibre of the heart contract after death from the inhalation of chloroform, so perfect was the paralysis; this applied to auricle as well as ventricle, and to the most powerful stimuli, including galvanism; whereas when the heart had ceased to beat from other causes, such as failure of respiration, etc. I often and often made it resume its work, to the re-establishment of the circulation, by the application of galvanism.

**Observation 1.**—When the heart is thus exposed, the movements of the whole viscus, and alternately of its separate parts, can be studied through the more or less transparent pericardium. (Should the pericardium be loaded with fat, it can easily be dissected off without piercing the membrane.) The artificial respiration being properly and rhythmically kept up, the facility and smoothness of the heart's action strikes the observer, any impulse or beat of the heart not entering into the mind. The point of the finger coming in contact with the ventricles, immediately dispels the deception, and the *apparent* blow is distinctly felt. A stethoscope, lightly applied, is raised against the ear, and the first and second sounds are distinctly heard.

**Observation 2.**—When the pericardium is removed, and its contained fluid consequently lost, the heart's action becomes immediately tumultuous; the contractions appear more forcible, and the sounds are much louder; and this is the character, more or less intense, of its action ever after. The pericardium, therefore, regulates the heart's movements.

**Observation 3.**—The first sound occurs during the contraction of the ventricles, and the second immediately follows it; that is, whilst the auricles are being filled with blood and no muscular action is going on.

It is necessary now to bear in mind, that the ascending portion of the arch of the aorta and the commencement of the pulmonary artery must be looked upon as heart when speaking of the movements of the latter; for they are equally contained within the pericardium.

**Observation 4.**—During the systole or contraction of the ventricles, the base of the heart approaches the apex; the latter at the same time is pressed downwards, backwards and from right to left, describing part of a circle: the ventricles assuming a contracted globular form descend, describing also part of a circle, but passing forwards and from right to left. There is also a forward movement of the left ventricle above the apex from left to right. These minor movements must be seen, they cannot well be described; but the facts of importance to be remembered are, that when the ventricles contract, their bases descend towards the apex, and the latter is not tilted forward so as to give any blow to the thoracic walls,

but is pressed down wards, its extremity being directed backwards and from right to left.

**Observation 5.**—The ventricles contracting, the auricles simultaneously receive blood and then occupy part of the space within the pericardium previously taken up by the ventricles in their relaxed distended state.

**Observation 6.**—With each contraction of the ventricles and descent of their bases, the pericardial portions of the aorta and pulmonary artery become suddenly greatly elongated and distended; and as suddenly, by their elasticity, react upon their contents, becoming of uniform calibre, but visibly distending the sinuses of Valsalva. The *venæ cavae* are similarly distended during the contraction of the auricles.

**Observation 7.**—The finger and thumb spanning the diameter of the ventricles are perceptibly further separated during the contraction of the ventricles, and approximated during their relaxation.

**Observation 8.**—The same *apparent* blow is felt over every part of the ventricles during their contraction, but more forcibly over the centre. The impulse at the ribs is most probably given by the fibres just above the apex.

**Observation 9.**—The apex is the most fixed part of the heart. Great pains were taken to ascertain whether the eye were deceived or not. A piece of string was stretched tightly across the thorax, and a pin thrust through it into the substance of the heart. The string acting as the fixed point, the oscillations of the pin corresponded to the movements of the part into which it was inserted. Thus when inserted about the centre of the sulcus separating the ventricles anteriorly, the head of the pin moved upwards during contraction of the ventricles, and downwards during contraction of the auricles, that is, in a reverse direction to that of the heart and the pin's point inserted into it. In this situation the pin moved longitudinally along a line equal to —, whereas, when inserted into the apex the distance did not exceed —. The same was tried over other parts of the heart, and always with the same result, *viz.* that the apex was more fixed than any other part.

A careful consideration of these observations shows that the heart's action is extremely simple; that there exists a reciprocity or compensation between the auricles and ventricles, and that, although the chambers of the heart are continually receiving and discharging their contents, these actions are so regulated that the bulk of the contents of the pericardium is always the same. For instance, when the ventricles contract, the loss of the bulk of the fluid they have ejected is made up, or compensated for, by the bulk of the fluid pouring into the auricles, and by the increased bulk of the pericardial portions of the aorta and pulmonary artery. This is shown in fig. 2,

FIG. 2.

FIG. 3.

where *a* represents the ventricles in their contracted state, *b* the distending auricles; (they do not become fully distended until the aorta and pulmonary artery have, by their elasticity, reacted on their contents, and have become of diminished calibre, the auricles still filling after the second sound is heard); *d d* the pulmonary artery and aorta greatly distended and lengthened; for observe, that the bases of the ventricles, from which these vessels spring, are lower than in fig. 3, where *a* represents the distended lengthened ventricles; *b b*, the auricles immediately after their contraction; *d d*, the pulmonary artery and aorta of diminished calibre with the semilunar valves shut down; *c c*, the pericardium of the same form in both diagrams.

This uniform shape of the pericardium is however departed from at the instant of the ventricular contraction, the change of form causing the impulse, which has erroneously been

attributed to the tilting forward of the apex, whereas it may be caused by any portion of the ventricles in contact with the thorax or diaphragm. Were there no opposing column of blood pressing upon the upper surface of the semilunar valves, there would be no blow or impulse caused by the ventricular systole. How much this impulse is augmented and communicated to surrounding parts where diseased valves obstruct the circulation, is too well known for me to enlarge upon here.

Do not let us then forget, in our physical examination of patients, that any part of the ventricles being in contact with the chest-walls will give, during contraction, an impulse.

We must now turn our attention to what is taking place in the interior of the heart simultaneously with the external conditions we have been noticing.

The cavities of the auricles and ventricles being at one time continuous with, at another separated from each other, by what means and at what time are these changes effected? In short, what are the functions of the auriculo-ventricular valves, chordæ tendinæ, and muscoli papillares? Also, What share does the blood take in these actions?

To determine these points I lately adopted the following method. A bullock's heart was obtained, and the auricles cut away nearly as low down as the auriculo-ventricular openings; the cavities of the ventricles were well washed out, and the coagula carefully removed. A vulcanised india-rubber tube of like diameter with the pulmonary artery was then attached, by one extremity, to the vessel, and by the other, to a common forcing pump; water was then thrown into the pulmonary artery, and the semilunar valves tightly shut down, gentle pressure being maintained, in imitation of what takes place during life. The right ventricle, being empty, was in the same state as when the auricle is about to inject it. On pouring water into the ventricle the flaps of the auriculo-ventricular valve rose upon the surface of the fluid, until (the ventricle becoming fully distended) the valve formed a perfect septum between it and the auricle. The left side of the heart was tested in the same manner, and with results perfectly the same, notwithstanding the greater thickness of the valve, the larger size of the muscoli papillares, and the stronger chordæ-

quotes some experiments by Fick. He says, "These peculiar structures are best shown by pouring in water from the pulmonary artery and aorta, until it reaches to a point in these vessels, which is somewhat higher than the region of the auriculo-ventricular valves." This, however, is a very different proceeding from that adopted by myself; the principle is different; nevertheless the true action of the valve is thus stated by Valentin further on: "The slightest pressure suffices to close the auriculo-ventricular valves—a very weak contraction of the walls of the ventricle—indeed, the mere force with which the blood is expelled from the auricle, and rebounds or is rejected by the elasticity of the ventricular walls, completely suffices for this purpose." I was entirely ignorant of anything of the kind having been previously done by Fick; suffice it to say, the thing was not only new to me, but to such men as Billing, Carpenter, Lane, Richardson, Leared, and others, and is not to be found in our standard works on Anatomy or Physiology, where, as is well known, the action of these valves is very differently stated. Ignorant, then, of any but hypothetical speculations as to the time and manner of the closure of these valves, I was led, by experiments, to treat of the matter as follows:—The auricles contracting on the blood, the force of their contraction is transmitted by the blood in all directions, separating the flaps of the valves, distending the ventricles, and (the semilunar valves being shut down) pressing as much upwards and backwards, as downwards and onwards. The force, not being sufficient to raise the semilunar valves, is expended in distending the ventricles, and raising and closing the auriculo-ventricular valves.

This simple, yet beautiful demonstration, is of great importance in solving the problems which have been engaging our attention.

Let the fact of there being a perfect septum between auricle and ventricle, previous to the contraction of the latter, be taken in connexion with the fact (as stated in Observation 4, and as shown in fig. 2,) of the descent of the bases of the ventricles during their systole, and we arrive at an important conclusion respecting the functions of the muscoli papillares. Seeing then that the valve forms the perfect septum as above, when the ventricle contracts as from *a*, fig. 3, to *a*, fig. 2, these muscles also contract in proportion as the base of the ventricle descends, and their tendons (chordæ tendinæ) being inserted into or connected with the under surface of the flaps of the valve, from apices to circumference, thus maintain the proper tension of the valve till the whole of the blood is expelled from the ventricle.

The auriculo-ventricular valve thus forms a perfect septum between the auricle and the ventricle as soon as the latter becomes distended, and is kept in this position during the whole ventricular systole by its own proper muscles, (muscoli papillares,) which, by contracting simultaneously with the descent of the base of the ventricle, prevent the eversion of the valve into the auricle.

The following table has been drawn up from the foregoing experiments and observations, and, if carefully studied, will greatly facilitate the comprehension of the heart's action, the time, and, as will be shown further on, the causes of its sounds.

FIG. 4.

FIG. 5.

tendinæ. Fig. 4 represents the right auriculo-ventricular, and fig. 5 the left auriculo-ventricular valves closed without the least pressure on the sides of the ventricles.

An account of this last experiment was given in the *Medical Times and Gazette*, December 26, 1857, since which Dr. Brinton has kindly informed me that the action of these valves had been previously shown to be passive. I find Valentin

#### Analysis of One Complete Action of the Heart.

Time occupied, say, one second.

Rhythm.	Time.	Order of Occurrences.	Muscular Action taking place.
Last part of pause.	↓	Auricles contracting. Ventricles distended with blood by the force of the auricles. Auriculo-ventricular valves closed.	Contraction of auricles.
First sound and impulse.	↓	Ventricles contracting on their contents; tension of the auriculo-ventricular valves and chordæ tendinæ; blood passing into and increasing the calibre of the aorta and pulmonary artery. Auricles relaxed, permitting the flow of blood into them from the vena cava and pulmonary veins.	Contraction of ventricles.
Second sound.	↓	Ventricles relaxing; auriculo-ventricular valves and chordæ tendinæ no longer tense; small quantity of blood passing into ventricles. Auricles filling with blood; calibre of the aorta and pulmonary artery diminished by the elastic reaction of their coats on the contained blood, producing forcible closure and tension of the semilunar valves.	None.
First part of pause.	↓	Ventricular fibres, auriculo-ventricular valves, and chordæ tendinæ, fully relaxed. Auricles distended with blood. Here the requisite condition of both auricles and ventricles is arrived at for a new set of actions.	None.

N.B. The above Table shows the contents of the pericardium, from the apex of the heart to its connexion with the aorta and pulmonary artery, always to be the same.

(To be continued.)

SERIES OF CASES ILLUSTRATIVE  
OF  
DISEASES OF THE ABDOMEN,  
AND ESPECIALLY OF THE DIAGNOSIS AND TREATMENT OF  
ABDOMINAL TUMOURS AND INTUMESCENCE.

By CHARLES J. HARE, M.D. Cantab., L.R.C.P.

Assistant-Physician to University College Hospital, etc.

MOVEABLE KIDNEYS—THEIR DIAGNOSIS AND  
TREATMENT.

(Continued from p. 87.)

**Case 4.**—The following case is one of considerable interest and importance, especially in connexion with the one (No. 2) above given, as showing the tendency in certain cases to permanent cure:—

Mrs. S. was under my care as an out-patient at University College Hospital, and complained of dull, aching pains, and dragging sensations in the loins, and other symptoms, which induced me to examine the abdomen. I then found that both her kidneys were moveable to a considerable extent, and I had the opportunity, on several occasions, of showing the case to the students as a well-marked example of the affection.

My friend, Dr. Gibb, recently informed me that the patient subsequently went under his care for an uterine affection, and mentioned to him that I had attributed some pains which she suffered from in the region of the kidneys, to a moveable condition of those organs. Dr. Gibb examined her abdomen, and found the kidneys in the state I had mentioned. He has since very kindly, at my request, furnished me with the following interesting particulars of the progress of the case:—

"Mrs. Stubbs, aged 45, mother of several children, first came under my care in 1854 for an uterine affection, and at the same time complained of much uneasiness in her left lumbar region, which she attributed to her moveable kidneys. I discovered them to be moveable, as described, but the left was more so than the right. Her health improved, her uterine affection was cured, and she became pregnant. During the early months of her pregnancy she suffered uneasiness, and sometimes pain, from what she felt to be the slipping up and down of the kidneys, especially of the left one. This wore off as gestation advanced, and on the 5th of May, 1855, I confined her of a girl. The labour was easy and natural, and on examining her some time after, the kidneys appeared to be less moveable, that is to say, their arc of motion was diminished, and she suffered no inconvenience from them. Her health was good, and she became again pregnant, and did not suffer this time from the kidneys, although she felt soreness in the left groin and side, but not in any way connected with these viscera. I attended her on the 22nd of May, 1857, and confined her of another girl, and the examination I made at the time and a little after convinced me the kidneys were not now, if at all moveable, seeming to have got back to their normal position and situation, most likely from being kept permanently so during her last pregnancy."

**Diagnosis.**—In very stout individuals, or when from any cause the parietes are particularly rigid and unyielding, the detection of a moveable condition of the kidneys, even when present, may be very difficult or even impossible; but under ordinary circumstances such is by no means the case. Nor when the presence of a moveable tumour, such as I have described, has been determined, is the diagnosis of its true nature a matter of great difficulty. The physical signs (mentioned at page 8) are of themselves almost sufficient to enable one to come to a positive conclusion on the subject; the chief errors having occurred when practitioners have been unaware of the occasional occurrence of this moveable condition of the kidneys. Under such circumstances the kidney has been mistaken for the spleen, "an abscess," some enlargement of the liver, or for a tumour of a malignant character; while I have long felt assured that some of the so-called "phantom" and "anomalous" tumours, (a) tumours, of which descriptions have been published, have in reality been kidneys presenting this unusual mobility.

Where the right kidney is enlarged and fixed in position, it is now and then very difficult to make an accurate diagnosis between it and some form of enlargement or tumour of the liver, but this organ never presents any mobility, such as does the moveable kidney. In several instances the condition of the right renal organ has been associated with enlargement of the liver, but the diagnosis is not then necessarily rendered more difficult, as the margin of the liver can generally be made out by palpation and percussion, and the kidney is found to slip readily beneath it. An enlarged gall-bladder is sometimes very moveable, but the position which it occupies is different from that of the organ under consideration, being usually more oblique towards the left iliac-fossa; the lower end of the enlarged gall-bladder is also more globular; it feels less hard under pressure, and sometimes fluctuation in it can be detected; besides, though the gall-bladder may be very moveable, it is the distal end only of it which is so, the other being attached to the liver. On the left side the spleen is the organ most likely to be confounded with the kidney; but if it reached as low as this organ it would be much larger than the kidney is, and when enlarged it is never, as far as I know, so mobile as is the so-called moveable kidney; the spleen is also more superficial and usually so much so as to be close to the parietes and dull on percussion, while the kidney (of its normal size) is covered more or less by intestine. It must be remembered, however, that in exceptional cases a coil of intestine may get between the abdominal parietes and the enlarged spleen, and so give rise to a resonant stroke-sound over that organ; while, on the other hand, if the moveable kidney be detrued downwards, and kept in front, it gives rise, *pro tempore* at least, to dullness on percussion. An ovarian tumour differs in its attachments; it is not so limited to one side of the abdomen, if, at the same time, it extends high up towards either hypochondrium; in other words, if an ovarian tumour extend high into the abdomen, it has always a considerable transverse diameter. A collection of feces in the colon is different in form and feel, nor will it slip into the hypochondriac region like the kidney. A cancerous or tuberculous mass growing from the omentum or mesentery, or a floating tumour in the peritonæum, is most likely to be confounded with a moveable kidney; but the loose tumours are extremely rarely of a kidney size, and a careful attention to the shape of the moveable kidney, and the extreme smoothness of the surface, will generally sufficiently solve the diagnosis, while the detection of the hilus of the kidney, which in favourable cases is quite possible, will place the matter beyond a doubt; it will be remembered, also, that as the kidney is detrued downwards, it assumes (as shown in the woodcuts) more and more of an oblique direction, the hilus looking more upwards, owing to the peculiar attachment of the organ. The absence of the kidney in its normal position, and the consequent depression there (when this occurs) are likewise important guides in forming an opinion; besides which the absence of any general cachexia, or of the symptoms of other disease, and the fact, sometimes ascertained, that the tumour since its first discovery has remained perfectly stationary as regards size, etc., will give some help in coming to a correct diagnosis.

**Sex, etc.**—I have been able to procure more or less complete accounts of twenty-three cases of moveable kidneys. Of these, a very ample account of one was kindly given me by Dr. Gueneau de Mussy; ten are recorded by Rayer (b) as having occurred in his own practice or in that of others; one is described by Nélaton (c), and another by Velpeau (d); a case is mentioned in the *Gazette Médicale de Paris*, 1846, p. 993; and one also by Mr. Adams (e) of St. Helen's-place; my friends, Dr. Rankin and Dr. Priestley, have given me some facts connected with two other instances of the affection; and six cases have occurred in my own practice. I have also met with indirect reference to other cases (f). Of the above 23 cases, 20 occurred in females and 3 only in males; of these 3 exceptional cases, one is quoted by Rayer, from Aberle, and the other two came under Rayer's own observation, and, curiously enough, both occurred in the persons of medical men. The ages at which the patients

(c) *Gazette des Hôpitaux*, 1854, p. 346.

(d) *Gazette des Hôpitaux*, 1853, p. 285.

(e) *Medical Times and Gazette*, 1857, vol. i. p. 661.

(f) Cruveilhier, *Anatomie Pathologique*, I. 722; Rokitanaky (*Syd. Soc.*) ii. 187. Dr. Simpson, of Edinburgh, *Med. Times and Gaz.* 1857, vol. i. 263; Prof. Oppolzer, *Med. Times and Gaz.* 1857, vol. i. 675.

(a) This view has also been suggested by Dr. Priestley in some interesting notes on "Hysteric Tympanitis," *Medical Times and Gazette*, 1857, vol. i. p. 262.

came under observation varied much; the youngest was an unmarried girl, aged 18, but in her case the mobility of the kidneys was comparatively slight; another, in whom the mobility of the right kidney was considerable, was 22. A case is mentioned by Rayer as having occurred in a "very old" woman; but out of 18 cases in which the ages were recorded, 10 occurred between the ages of 30 and 51. With regard to the relative frequency with which the two kidneys are affected, in one of Rayer's cases (Obs. v. p. 786), the mobility of the two kidneys was equal, though in that particular instance the left kidney was situated rather lower than the right one; in 4 other cases (Velpeau's, Nélaton's, the one in the *Gaz. Méd. de Paris*, and one of my own) the left kidney was the more moveable, but in the remaining 17 (g) the right kidney was solely or chiefly affected. In 5 of these 17 cases the left kidney was stated to be in the "normal position," or "not affected;" in 5 others both kidneys were moveable, though the right one was decidedly the more so. I am inclined to think that this number (5 in 17) does not represent the actual frequency with which both kidneys are to be found affected in the same subject, for in the 17 cases of mobility of the right kidney, no mention whatever is made of the condition of the left kidney in 6; and in another case (Rayer, p. 786) the position of the left kidney could not be "exactly determined." As of the above 5 cases of partial mobility of the left kidney when the right one was considerably (or at least, chiefly) affected, 4 occurred under my own observation, it is probable that, if the exact condition of both organs had been in all cases recorded, the occurrence of mobility in the two kidneys would have proved to be of more frequent occurrence than is shown by the above analysis. Oppolzer mentions that he has met with "cases in which it was observable in both kidneys, and that in a remarkable degree."

*Pathology, Causes, &c.*—This condition of the kidneys may be either congenital or acquired. Where these organs are situated permanently low down in the abdomen an abnormal origin of the renal arteries has been almost always met with; but in the cases under consideration, though the vessels have been found lengthened, their origin has been at the usual position, and I do not think that some lengthening of the vessels is a necessary proof of the mobile condition of the kidneys having been congenital. It is well known how readily the vessels of the ovaries, for example, accommodate themselves to the altered position of these organs when, from adhesion to a pelvic tumour they are removed perhaps to a distance of many inches from their natural position. The condition is sometimes associated with an enlargement of the liver, which may tend to push down the kidney. A large calculus in the pelvis of the organ will sometimes drag down the kidney, but no condition of this kind is at all essential to the detraction of the organ, for in almost every instance in which a post-mortem examination of such cases (the patients dying of other disease) has been made, the kidneys have been healthy, as stated by Oppolzer, Rayer, etc. The latter author mentions that the moveable condition of the kidneys is sometimes coexistent with a displacement of the intestine or of the uterus (though it does not seem clear how the latter cause could produce such an effect), and that "frequent pregnancies, efforts to carry or lift heavy weights, have appeared in some cases to be the cause of this displacement of the right kidney, which, in other instances, has been inexplicable." Emaciation in those who have been stout appears to be one cause of the mobility of the kidneys. Oppolzer observed that while the organs themselves were healthy there was a deficiency in the cushion of fat, and an extension of the renal vessels; while Mr. Adams, with reference to the case he records (*loc. cit.*) remarks, "The only peculiarity remarkable was that the kidney appeared bound down in its situation more loosely than usual, and the old lady, from having been very fat, had become somewhat thinner, and her integument appeared very lax throughout." Rayer mentions a case in which the peritonæum, instead of passing only over the anterior surface of the kidney, enveloped it at every part except at the hilum, and thus formed for it a true mesentery nearly two inches in length; and another example is alluded to by Dr. Priestley as having been observed by Dr. Simpson (h) in which "the peritonæum

was found reflected over the posterior surface of the kidney, giving it thus a mesentery, and allowing it very considerable motion on the right side of the abdomen."

*Treatment.*—Owing to mistakes in the diagnosis of affections of this kind, patients have been subjected to courses of treatment not only useless, but painful and injurious, while they have also been rendered very anxious by not finding the "tumour" disappear. Besides various other kinds of "active treatment" submitted to, one patient came under Rayer's care, with the abdomen, especially the right flank, covered with leech-bites, and another had had a moxa applied. Patients suffering from this affection should avoid long-continued standing, or much exercise, especially of a severe character, such as running or jumping, riding on horseback, or travelling over rough roads. Straining at stool should also be prevented as much as possible; the bowels should be regulated, and any obvious indication for the improvement of the general health should be followed out. In two or three of the cases I have seen the patients have been somewhat anæmic, and a course of steel medicines has appeared not only to have improved the general condition, but to have aided in relieving the dragging pains of which they complained. Warm baths often give great temporary, if not permanent relief, and a large belladonna plaster spread on leather has proved useful; but this might perhaps be partly due to the support it yielded. But the greatest and most efficient relief is obtained from the use of an elastic abdominal support, provided this be made so as to fit thoroughly well; if not, it sometimes rather aggravates than relieves the pain: and one difficulty lies in preventing its slipping too high up on the abdomen, when it acts somewhat like a belt round the waist, and may even tend to detract the kidney downwards. Dr. Gueneau de Mussy has informed me that he ordered the lady who was under his care with this affection to have the bowels well opened every evening, and then in the morning before rising (while the kidney, therefore, is in its most normal position) to slip over the lower extremities, and so move it upwards till it encircled the abdomen, an elastic circular bandage or support; applying underneath it, opposite the right antero-lumbar region, a hair pad. The lady soon became accustomed to the pressure, and is now almost free from pain, although she has resumed her former mode of living, taking considerable exercise, and mixing much in society. I think these suggestions as to the time and mode of applying the support of much practical importance.

## A CASE OF TRAUMATIC TETANUS SUCCESSFULLY TREATED.

By WILLIAM H. DAKERS, L.S.A.

House-Surgeon to the Ardwick and Ancoats Dispensary, Manchester.

Henry Wilding, aged 32, machine glazer; married; of a sallow complexion; of intemperate habits, and an inveterate smoker. Admitted March 10, 1857.

The ring finger of his right hand presented a contused, lacerated appearance, and he was ordered to poultice it.

March 19.—The finger is in an unhealthy-looking, sloughy condition, with the extreme phalanx partly laid bare. He complains that his belly pains him very much. He protruded his tongue with a tremulous movement, and complained of a dragging sensation at its root. Upon close questioning I ascertained that the first appearance of uneasiness about the neck presented itself on Monday the 16th inst. He cannot open his mouth more than an inch. Tongue white and loaded; pulse natural. Dressed the finger with Cer. resinæ and a few drops of creosote. Ordered him Pil. Plummer, five grains three times a-day, and the following mixture:—

℞ Sod. sesquicarb. ʒss., æth. chloric. ʒss., julep. ammon., mist. rhei co., inf. cascarril. aa part. aq. a ʒviij. M. ʒj. 4tis h. s.

20th.—Requested Mr. Ledward to see him, and by his advice I amputated the extreme phalanx; not, however, for the trismus, but on account of the unhealthy condition of the finger and the bone exfoliating. While under the influence of the chloroform the muscles of mastication did not relax, but the facial muscles and the muscles of the neck twitched convulsively. His bowels are now open.

Ordered—℞ Pulv. lobel. infl. ʒss., pulv. capsici, gr. iv. M. st. s.

(g) In one instance out of the twenty-three it is not mentioned which kidney was the mobile one.

(h) Medical Times and Gazette, 1857, vol. i. 26.

℞ Hyd. chlorid. gr. vi., pulv. jalap. ʒj. M. 3tis h. s. post pulv. supra.

℞ Pil. Plummer. gr. v., 3tis h. s.

℞ Quin. et ferri citr. ʒij., tinct. lobel. ʒij., inf. quassia: ad ʒviiij. M. ʒj. 4tis h. s.

21st.—Cannot open his mouth at all. The calomel purged him a little. The lobelia did not make him vomit; has passed a restless night, and only dozed a few minutes at the time. Stump looks well. RepARATION active. Ordered him a warm bath, and a large linseed-meal poultice to be applied round the neck.

2 p.m. Can swallow, but with difficulty.

3.30 p.m. Mr. Harrison saw him with Mr. Ledward and myself; his gums are slightly affected, and the mercurial fetor of breath is perceptible. At Mr. Harrison's suggestion I applied a poultice to the finger, and rubbed in the following ointment along the whole course of the spine.

℞ Aconitina, gr. iv., axung. ʒi. M., ʒi. 2 dies horis infric.

10 p.m. Continue with the iron and quinine. Pulv. Doveri ʒi has.

22nd, 10 a.m. Discontinued the mercurial—salivation being fully established; he has taken in all 16 grs. of calomel.

2 p.m. Ordered a turpentine enema with three drachms of tinct. lobel. in it. This brought away a large quantity of filthy dark matter, resembling faeces mixed with pitchy matter, with an exceedingly offensive smell.

No effect having been produced by the aconitina (which I had procured in Manchester), I concluded it was bad. I therefore telegraphed to Messrs. Morson of Southampton-row, London, who sent me down some pure aconitina by mail train.

10.30 p.m.—Greater difficulty in swallowing; feels very poorly; is thoroughly nauseated by the lobelia. Complains of intense pain down the back, with severe shooting pain from the chest round to the spine. Gave him Pulv. Doveri ʒi.

23rd. 3. 30 a.m.—The aconitina having arrived, I had more of the ointment rubbed in.

10 a.m.—Complains of his mouth watering, and his tongue, and all down his back feeling numb. I ordered the ointment to be rubbed in every four hours instead of every two hours. Passes his urine with great difficulty.

10 p.m.—Rep. enema sine lobel. Pulv. Doveri ʒj. st. s.

24th.—Ol. ricini ʒij. Pulv. Doveri ʒi. has.

25th.—Cannot open his mouth: has "risus sardonius." Ordered Ext. cann. Ind. res. gr. iʒss 4tis h. s. Discontinued the aconitina ointment.

26th. Requested Mr. Dumville, Consulting Surgeon to the Institution, to see him, who advised a continuation of the same remedies. Opisthotonos being fully developed, I applied a blister to the whole length of the spine.

27th.—Bowels obstinately constipated. Ol. ricini ʒij. with ol. tigllii mʒij. Continue with the iron and quinine without the lobelia. Increased the dose of ext. cann. Ind. res. to four grains every three hours.

28th, 10 a.m.—He now presents a fearful spectacle: the eyes are protruding, the countenance horribly distorted, the alæ nasi distended, the corners of the mouth drawn up, exhibiting the tetanic grin; his belly is like a deal board for hardness, and he rests on his head and heels.

Gave him ʒj. doses of ext. cann. Ind. res. every three hours. Ol. ricini ʒij., ol. tigllii mʒj. st. s.

Is seized with opisthotonos each time he attempts to set the voluntary muscles in action.

4 p.m.—Can open his mouth a little and can swallow, but says his belly is very painful.

30th.—Fits get stronger and more frequent; they are induced by the merest trifle—the opening or shutting of the door or window, or the sight of a strange face is sufficient to induce one. Complains of intense pain "*when the stretching bouts are agait.*"

Continue with the ext. cann. Indio. resin., ol. ricini ʒij., ol. tigllii mʒj. st. s.

31st.—Bowels are purged. At Mr. Ledward's suggestion I gave him the following draught:—

℞ Tinct. aconiti, P.L. mʒ., tinct. conii, mʒv., acid. hydrocyan. Scheeli, mʒ., aquæ q. s. Ft. haust. 2dis qq. h. s.

April 1st.—Is much better. Bowels are much purged.

10 p.m.—Can open his mouth better. Says he has had no pain in his belly since he has been purged.

4th.—Diarrhoea ceased. No pain in the belly; can swallow well, and can open his mouth wide. Finger looks well,

rather painful; granulations healthy. Continue with the mixture three times a day.

5th.—When I saw him to-day he was eating a beefsteak, and apparently relishing it.

17th.—Came up to the Dispensary. Finger nearly healed up. Continue with the iron and quinine without the lobelia.

20th.—Discharged cured.

I have here given the history of the case as it fell under my notice. I leave the Profession at large to make their own comments upon it, merely remarking, that after exhibiting such a catalogue of remedies, it would be impossible to say to which of them his recovery is to be ascribed; but were I to have a similar case, in the present state of knowledge, I should feel inclined to treat it in a similar manner.

Ardwick and Ancoats Dispensary, Manchester.

## MEDICAL SKETCHES FROM EGYPT.

WRITTEN DURING A JOURNEY ON SERVICE FROM ENGLAND TO INDIA.

By FREDERICK ROBERTS, Esq.

Staff-Surgeon.

I visited this morning the Military Hospital and Medical School of Cairo. The Arab name of the Hospital is "Casn-el-ane," or House or Castle of Ophthalmia; or, according to another conjecture, "Casn-el-Eyn," after the mosque of El Eyn, close by. It is situated on the way to Old Cairo. I presented my card to Professor Diamanti, a Roman, who at the time was engaged in delivering a *lecon* to his Egyptian pupils—sitting in Turkish fashion on mats, and taking notes in Arabic from an interpreter, who received the letter in French from the Professor of Therapeutics. The Director-General and chief of Surgical Clinique, and Professor of Surgery, is M. Reyer, who was absent this day on account of sickness. The Professor of Ophthalmology is M. Hossenoff, an Egyptian, who received his professional education at Vienna, and where, from his Russian-sounding name, as he facetiously remarked to us, he was accordingly often taken for a native of that country, however little his complexion lent a probability to such a presumption. In consequence of the absence of M. Reyer, I was accompanied round the wards and building by Professor Diamanti and M. Fousi, an Egyptian gentleman, who is assistant to M. Reyer.

This Hospital, which is nearly a square in figure, contains an interior area planted with trees, which afford an agreeable shade to the patients. There is a wide corridor between two lines of lofty and airy *salles*, which are provided with iron bedsteads with boards, in place of canvas stretchers, and mattresses and linen sheets. The institution is made to contain eight or nine hundred patients. There were present this day about four hundred sick soldiers and nearly two hundred civil patients. They are well found in diet and everything else, I was assured by an European, M. Diamanti. Indeed, so greatly does the present Pasha pamper the soldier, that he lodges them in some of the best palaces, which are allowed to be much abused by them. The lecture rooms and laboratories were all complete, but had the air of neglect about them. In the dissecting-room was a subject waiting a *sectio*. In the corridors were unopened cases of the anatomical wax preparations of Azan of Paris; and in the museum were the same, as well as preparations made out of the human body. I observed three perfect specimens of exhumed running ibis, with white body and dark blue wings and tail, in the museum, which contained chiefly the indigenous specimens of natural history. The library was small, but comprehensive, and included none but French books. There were three volumes of Hunter's works in French.

*State of Public Health.*—In consequence of the rigid rules of the Council of Health, mortality has greatly diminished of late years. The classes who still suffer from an unusually high rate of death is the very young population and women; as mothers will not see doctors either for themselves or children. Their prejudices against educated doctors are left more unmolested than those of the male population, who are more amenable to sanitary discipline. The Council of Health is established on very decided principles here, and is in relation with those of other countries of Europe. It is presided over by Clol Bey, who now-a-days passes his time between Cairo

and Alexandria. He had retired from the Egyptian service for a time, and was recalled into activity by the reigning Prince, Said Pasha.

There is no Medical journal published in Egypt for the maintenance of Medical literature, but there is communication with the Paris Medical press. The state of public health is, nevertheless, constantly before the eyes of the authorities. Great amelioration in disease, especially ophthalmia, has been produced by instituting compulsory vaccination. At least it is so far compulsory that parties concerned are punished when an individual at death is found unvaccinated, as I understood from M. Diamanti. The strictness in exacting measures both for public and private hygiene among all classes, is supposed, not without plausibility, to have caused the immunity from plague for seventy-two years—since 1835. The prevalence of purulent ophthalmia is also greatly reduced. There was no case among many of diseases of eyes equal to what I have seen in Europe. I saw the worst and only case of it in the Hospital, and which was nothing but ordinary chemosis, with some discharge. There is considerable alternation of temperature in the twenty-four hours, which M. Diamanti considered unfavourable to phthisical patients. He says also that people (natives) suffer not infrequently from rheumatism in the country, on account of the inequality in the temperature of the day, and that of the night.

**Surgery.**—I saw several cases of fracture of the lower extremities, including three of the femur, treated with straight splints at the side, extension and counter-extension being made at either end on the long splint. In compound fractures the many-tailed bandage was in use; and in simple cases a couple of strong, straight splints, more than half an inch thick, cushions, and a little slight bandaging constituted the setting apparel. I saw no double inclined plane in use in any of the cases. I had no reason to believe that this branch of surgery was not successful, but from the scientific principles adopted, simple, at the same time good material employed, I should presume it to be attended with happy results. I did see one case of a fracture of both bones of the forearm united rather crookedly, but with retention of the perfect motions of the various joints: Fractures of the tibia were treated with the straight, thick splint, apparently with prospects of success. In a case of compound fracture of the thigh, charcoal was used to deodorize the wound.

To inquiries about the use of the starch and gypse bandages, I was told that they were both used occasionally, although there were no cases actually treated by these methods. Sentin's modification of the starch bandage was not used.

**Amputations.**—I saw nine or ten cases of amputation of the upper and lower extremities. There were two circular, and the remainder flap operations. Even in the flap cases sutures were not used, but simply adhesive plaister, as sutures are found to become sources of abscesses in the stumps in this country. In addition to the plaister, the rest of the dressing was charpie and bandages. All the cases were doing well, and bore no signs of pyæmia or gangrene, which I was assured was rare in the practice of the hospital. In one case of amputation below the knee hæmorrhage had taken place, and the femoral had been tied. The injuries requiring amputation, and the fractures had all been produced in mere working on the railway.

Stone in the bladder was a common disease under treatment, and several cases had undergone operation. There were a great number of cases of hydrocele also. Some had been treated by simple incision, and others with injections of iodine. Both M. Diamanti and M. Fousi informed me that diseases of the testicles were very frequent in the country.

**Circumcision.**—I saw a few cases of this operation which had been performed with a common razor (not I presume that scalpels were rare, but probably from prejudice). The prepuce was very neatly held together with a few small wire tenacula. In two cases the operation had been performed in young soldiers for religious purposes. On the same account the operation is common in the very young and very old among the poor population.

**Diseases of the Eyes.**—The Professor of Ophthalmology, M. Hosenoff, was not present when I was taken round the ophthalmic wards, and I lost some interesting details upon these diseases on that account. The Professor, however, offered to meet me at the hospital the next day, but an obliga-

tion to prosecute my journey precluded the possibility of my doing myself that pleasure. (The ophthalmic wards were fine, lofty, and airy rooms, furnished with blinds, which threw not too obscure a light on the rooms. Cataract was very common in the hospital, as well as in the country. Operations for the diseases were frequent in the hospital. I saw one or two cases of plastic surgery of the eyelids neatly done.)

Ophthalmia, as before observed, is much less prevalent in Egypt at the present day than formerly. Its causes are considered by M. Diamanti to be more mechanical than meteorological. The theory of cold and warm humidity (so tenaciously defended at the ophthalmological congress at Brussels by M. Anagnostakis, of Athens) does not appear to be tenable as an exclusive cause of the disease in Egypt or Greece, inasmuch as this humidity of different temperatures is equally as prevalent in the desert, where there is no ophthalmia scarcely, as in the towns and villages. Unless the wind is very high there is no dust in the desert, but a most refreshing cool breeze wafts over it when the thermometer is even upwards of 90° in the shade. Indeed, the European inhabitants of both Cairo and Alexandria build houses in the desert to obtain cooler residences than the cities afford. There is always more dust also in towns, where there are high buildings, which create strong currents and irregular blasts of air. In Egypt the privies, even in private houses, are open and numerous, and emit ammoniacal and nitrous gases, which are deemed irritating causes of ophthalmia in the country.

Cairo.

## THE LONDON PRACTICE OF MEDICINE AND SURGERY.

### THREE CASES ILLUSTRATING THE USE OF THE ÉCRASEUR IN THE REMOVAL OF UTERINE POLYPI.

#### Case 1.—ST. GEORGE'S AND ST. JAMES'S DISPENSARY. SUCCESSFUL REMOVAL OF A LARGE INTRA- UTERINE POLYPUS.

(Under the care of Dr. PRIESTLEY.)

Mrs. B., admitted as a patient at St. George's and St. James's Dispensary, under the care of Dr. Priestley, complained that she had suffered from severe and protracted menorrhagia, large clots passing occasionally from the vagina. She was exceedingly anæmic, and had the usual symptoms arising from loss of blood.

On examination by the vagina, the os uteri was found dilated, and the uterine cavity formed a continuous canal with the vagina, a smooth ring indicating the line of demarcation between the two. Inside the uterus, and with its lower extremity reaching down to the smooth ring indicating the os uteri, was found a firm rounded tumour, the size of an orange. Its attachment was posterior and near the fundus uteri. It had no suspending narrow peduncle, but was sessile, with a base of attachment as broad as the tumour itself. A doubt was at first entertained, from its peculiar form and relations, whether it might not be an inverted uterus. The history did not confirm this, however, and the uterine sound, passing easily upwards four or five inches along the anterior surface of the tumour, left no doubt that it was an intra-uterine polypus.

When the relations of the tumour were accurately ascertained it was proposed to postpone its removal for some little time, in the hope that the uterus would make an effort to expel it, and thus form an elongated peduncle, which might be divided with less risk. Hæmorrhage recurred, however, to such an alarming extent that interference became imperative. On the 3rd of July, therefore, Dr. Priestley, assisted by Mr. Spencer Wells, proceeded to excise the mass. The instrument employed was the double-action écraseur, kindly lent for the purpose by Dr. Savage, and which was curved in form, to adapt it to the axes of the pelvis. The patient being placed on the left side, the polypus was first

seized with the vulsellum, and while by means of this gentle traction was made downwards, the chain of the *écraseur* was passed first over the vulsellum, and then over the polypus up to its attachment in the cavity of the uterus. Great care was necessary in pushing up this chain along the genital passages, as, from the irregular form of its divisions, fear was entertained of lacerating or abrading the vagina or uterus.

The base of the tumour being at length reached, the chain was gradually tightened, and in about a minute and a half no further resistance was encountered; the polypus was found loose in the uterine cavity, and was removed by the vulsellum. Scarcely any hæmorrhage followed. A small clot, perhaps half an ounce in weight, was removed, and a piece of sponge placed in the vagina. When the sponge was removed the following day, it was scarcely stained with blood, showing that no after-hæmorrhage had ensued. Little pain was complained of during the operation, and except that diarrhœa supervened on the fourth day, there were no unfavourable symptoms. A week after the operation the patient was convalescent, and made an uninterrupted recovery. She is now well, and has had no recurrence of the hæmorrhage; the uterus being nearly of its normal dimensions.

The advantages of the *écraseur* were particularly manifest in this case. The urgent symptoms of the patient necessitated immediate interference, and the broad attachment of the tumour rendered an operation by excision little less formidable than a so-called enucleation. Removal by a sharp cutting instrument would have threatened severe hæmorrhage, not readily controlled by plugging, when the uterus was so flaccid and dilated; while separation by ligature in the ordinary way would, on the other hand, have exposed the patient to all the dangers arising from such a mass slowly putrifying in the vagina.

Dr. Priestley suggests that it might be advantageous to replace the usual hinge-jointed chain of the *écraseur*, which is managed in such cases with difficulty, by a silver wire, or small linked curb chain. Dr. H. R. Storer, of Boston, U.S., has successfully excised the hypertrophical cervix uteri, by an *écraseur* furnished with a silver wire; and Dr. P. believes that a wire or curb chain would be passed more easily round a tumour in the uterus or vagina, and that tightened by the *écraseur* it would act efficiently in cutting through the substance of a tumour or polypus.

## Case 2.—SAMARITAN HOSPITAL FOR WOMEN.

### LARGE MUCOUS POLYPUS REMOVED WITHOUT HÆMORRHAGE.

(Under the care of Dr. SAVAGE.)

A woman, aged 45, was admitted into the Samaritan Hospital, under Dr. Savage, for obstinate menorrhagia, which had resisted all the usual remedies. Frequent examinations had been made by various practitioners, on the suspicion of polypus, but no such tumour, or any tangible cause for a menorrhagia so rebellious could be made out. Dr. Savage, believing he could put something within the os uteri, which was large enough to admit the forefinger, directed that it should be dilated by sponge-tents. In a few days a large polypus could be felt protruding from the os. It was seized with a pair of ring forceps; very slight traction sufficed to draw the tumour further out, so as to disclose its place of attachment and size of its pedicle. The size of the polypus was that of a large pear, and that of its pedicle not much less. The patient was placed on her left side, in the ordinary position of delivery. The chain of the *écraseur* was carried up as high as possible, and the entire polypus came away, without the least hæmorrhage, in about six minutes. The patient complained of no pain whatever during the operation.

Dr. Savage remarked, that uterine polypi would be the triumph of the *écraseur* system. He could not imagine a more efficient or safer instrument than the double-action *écraseur*—M. Mathieu's latest improvement—for bloodless operations. The position of the patient, on the left side as in delivery, was found the most convenient. The chain certainly did require a little careful manipulation. It is flexible only in one direction, and when loose gets into embarrassing short curves, but the forceps fixed on the polypus acted as a capital director, and, thus guided, the single forefinger eventually carried the loop to its destination, ascertaining

at the same time that nothing wrong was included. For uterine purposes the *écraseur* is longer, and has a curve, giving it a still more ungainly and unpromising look; however, it followed the chain with the utmost facility, quite into the uterus, the tumour in this instance being constructed where any form of ordinary ligature could only have been applied with extreme difficulty, if at all.

No chloroform was administered. The patient was frequently asked whether she felt any pain. The polypus might, of course, have been cut through in a much shorter time than ten minutes, but its feel was suggestive of vascularity, and notwithstanding the urgent recommendations of some Surgeons of the plan of excision without ligature, the probability of hæmorrhage is by no means a settled question. The handle of the *écraseur* was worked only at half-minute intervals, so as not to throw a chance away. All hæmorrhage ceased from the moment the polypus was removed, and the patient rapidly recovered without a bad symptom.

## Case 3.—UTERINE POLYPUS— GREAT HÆMORRHAGE—SUCCESSFUL USE OF THE ÉCRASEUR.

This case occurred in the private practice of Mr. Worthington, of Lowestoft, and is described by that gentleman as follows:—

Mrs. —, a widow lady, aged 50, naturally of robust habit, from the town of Leicester, became fearfully blanched and prostrated by frequent and sudden discharges of blood from the uterus.

It was during a fit of syncope, arising from a sudden gush of blood from the uterus, that I was hastily called to see her.

I was informed she had been under medical treatment for the last two or three years, but no uterine examination had ever taken place. On introducing my hand into the vagina I at once detected, as the source of hæmorrhage, a large fleshy pedunculated polypus, of pyriform shape, growing from just within the cervix, on its anterior part, and descending into the vagina.

At the end of a few days the patient had sufficiently recruited to warrant me in proposing its removal, which I conceived, after consultation with Dr. Webb and Mr. Spencer Wells, might be advantageously accomplished by means of the *écraseur*. No difficulty was encountered in passing the loop of the chain over the tumour, so as to encircle its neck. This having been accomplished, the chain was gradually tightened, and at the end of half an hour, pausing from half to one minute, the tumour was lying loose in the vagina.

Nothing could be more satisfactory in its result. By the combined agency of chloroform the operation was rendered painless, and what was of still greater importance, owing to the anæmic condition of the patient, bloodless. Upon the most careful examination not a teaspoonful of blood escaped during the process.

The advantages accruing from the use of the *écraseur* in this case when compared either with excision or strangulation by ligature was strikingly manifest. Had the former been adopted the patient might have been exposed to hæmorrhage, dangerous to life, however slight. Had the latter been substituted, a putrid mass must have been left slowly to escape, which would necessarily have retarded recovery.

A speedy restoration to health took place; at the end of three weeks the patient was sufficiently recovered to enable her to return home to her friends.

## THE CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST. ILLUSTRATIONS OF THE TREATMENT OF THROAT AFFECTIONS.

(Cases under the care of Drs. PEACOCK, BENNETT, and BIRKETT.)

(Continued from page 88.)

THE following is a good example of the class of cases often met with in which the liability to recurrent attacks of catarrhal aphonia is associated with tendency to phthisis. These cases have no claim whatever to the designation of "laryngeal phthisis," which ought to be always restricted to those in which the existence of actual tubercular ulceration

of the mucous membrane of the larynx is diagnosed. The loss of voice in them is evidence only of a general susceptibility of the mucous lining of the air-passages, and has only the same relation to the phthisical diathesis that the liability to slight bronchitis and to colds in the head have when they occur under like conditions.

*Case 7.—Catarrhal aphonia, recurring every winter for nine years.—Phthisical tendency.—Treatment by tonics, cod-liver oil, and local applications.—Recovery in three months.*—Martha Snelling, a domestic servant, aged 21, was admitted on December 19, 1853, under the care of Dr. Risdon Bennett. She spoke in a low soft whisper, and stated that she had lost her voice without intermission for three weeks past. For nine successive winters she had been liable to it, and seldom recovered until the warm weather returned, never, indeed, even in summer, regaining a strong voice. The attacks, she said, always began with a bad cold. Her aspect was anæmic and delicate, and she had a troublesome cough. The pharynx was pale and relaxed. The cough was troublesome, and attended by a good deal of mucous expectoration. The catamenia were reported scanty, and the pulse was somewhat quickened. Ordered:—A draught containing quinine and iron three times a-day, a five-grain aloes and myrrh pill every night, and the weekly application of the nitrate of silver solution to the larynx.

The application of the solution was repeated on the 29th, and on July 9, 16, and 23. On the last-mentioned date the note states, "Voice much better; aspect delicate, and eye decidedly phthisical; much expectoration of phlegm, but no hæmoptysis; expiration harsh and prolonged over the right apex."

On Feb. 13 the note is "The voice is now much clearer than when she came, but still husky." On the 20th, as she was still losing flesh, the cod-liver oil in two-teaspoonful doses thrice daily was ordered. In addition to a continuance of the nitrate of silver to the larynx, the strong solution of iodine was now painted on the outside of the throat.

The oil suited remarkably well, and she gained strength fast. Counter-irritation by means of the iodine solution was had recourse to several times, both to the throat and over the upper part of the sternum. On April 3 her voice had for some time been clear, and her general health was so much benefited that she was allowed to discontinue treatment and discharged. The same tonic mixture had been persevered with throughout.

We have noted in a previous part of this report that external counter-irritation does not appear to be of much benefit in the hysterico-catarrhal form of aphonia, and that the mopping of the glottis itself with the nitrate of silver solution is a preferable practice. In the phthisical forms of chronic laryngitis, on the contrary, derivative counter-irritation is, according to the evidence before us, of great use, whilst the application of caustic to the part itself has often appeared to irritate rather than otherwise. We have often heard Dr. Peacock in particular remark that he had never seen much benefit derived from the employment of the latter in this form. The following case shows the good effects of the iodine paint.

*Case 8.—Laryngeal hoarseness, of three months' duration, with phthisis.—Cure of the hoarseness by a single application of the iodine solution.*—Harriet Martin, aged 32, a married woman, residing at Sydenham, was admitted on August 7, 1853, under the care of Dr. Birkett. She had suffered from the ordinary symptoms of phthisis for nearly a year, and had been persistently aphonic for three months. The loss of voice had begun during a severe cold, had soon become complete, and had never since been in any degree relieved. On making a great effort she could produce a husky voice. No paroxysms of dyspnoea had ever occurred, nor had there been any difficulty or pain in swallowing. On inspecting the throat the epiglottis was seen to be thickened, congested, and roughened. She had taken many emetics, but no form of counter-irritation had yet been applied. Although decidedly of phthisical aspect, and losing flesh, she was still moderately stout. The solution of iodine was ordered to be freely painted on the throat externally, and she was to take the cod-liver oil and a demulcent cough mixture three times daily.

On her second attendance she could speak almost clearly, and stated that her voice had been regained on the third day after the application of the iodine. The latter had caused most severe pain, and the part was still very sore. After this

it was not found needful to employ any other local treatment, since her voice remained, excepting a slight huskiness at times, quite clear. Constitutional treatment, by the oil and an expectorant mixture, was persevered with for three months, when she was discharged, much relieved in all respects.

It may be here remarked that the use of a very painful counter-irritant is much better than of a mild one, in almost all forms of chronic laryngeal thickening. The practice of this Hospital affords very frequent examples of how often after sinapisms, or even blisters to the throat, have failed to produce material benefit, the application of the solution of iodine will at once clear the voice. Not unfrequently, as in the above case, a single employment of it will suffice, though generally, in order to effect a cure, it is required two or three times, with intervals of about a fortnight. The solution used is a saturated one of iodine with iodide of potassium in alcohol; and if painted two or three times over the same surface may be made to vesiccate most severely. The pain caused, as the writer knows from personal experience, and has been assured by many patients, far exceeds that of a mustard plaster or a blister. It usually lasts for an hour or so, and leaves much soreness for several days. Although the application will produce general vesication, yet it never raises large bullæ, and the loss of serum is trifling. Its effect is indeed that of a typical counter-irritant. The mode of applying it at the Chest Hospital is usually to paint a surface about the size of a large watch-face on each side of the throat, on a level with the thyroid cartilage. The subjoined cases are in further proof of the efficacy of this remedy.

*Case 9.—Chronic laryngitis, with extreme hoarseness of seven months' duration.—Incipient phthisis.—Cure after a three months' treatment by iodine counter-irritation and tonics.*—Thomas Jones, aged 45, a cheesemonger, was admitted under the care of Dr. Birkett. He was extremely hoarse, and scarcely able to articulate so as to make himself understood. No stridor, and no pain in swallowing. The hoarseness began after a catarrh seven months before, and had continued without intermission ever since. He was pale and thin, but there were no signs of advanced pulmonary disease. There had been very little expectoration, and no hæmoptysis. He had been under much previous treatment, but without benefit. The application of the iodine paint to the throat was ordered, and was made very freely. A quinine and sulphate of iron mixture was prescribed to be taken three times a-day.

On the third day after the painting, very manifest improvement in the voice had taken place. The application was continued with fortnightly intervals to the seventh time, the tonic mixture being also persevered with.

On August 24, (six weeks after admission,) he was allowed to leave for a fortnight in the country. The note states that at this time the voice was much improved, but still not clear. He had gained in flesh and strength.

He was discharged on October 14, (fourteen weeks after admission.) He was able at this time speak loudly, and at times as clearly as ever he could. After much talking he again became hoarse, and usually the voice had a very slight huskiness. He speaks with a greater effort than prior to the attack. The improvement had been most marked after each successive application of the iodine.

*Case 10.—Chronic laryngitis (tuberculo-catarrhal), with extreme hoarseness.—Phthisis.—Great benefit from the use of iodine counter-irritation, and tonics.*—William Brown, a carman, aged 47, was admitted under Dr. Birkett's care on June 1. He was considerably emaciated, and of almost icteroid aspect, having been losing flesh for eight months, with much attendant cough and expectoration. For five months his voice had been gradually getting more and more hoarse. The sputa had twice been tinged with blood. The hoarseness was extreme, and the attempt to speak, as shown by the way in which the head was thrown forwards, etc., was difficult and painful. There was much soreness of throat, and some pain in swallowing. The dusky complexion manifested that the entrance of air into the chest was greatly impeded, while the state of cachexia attending it made the suspicion of tubercular deposit very probable. The mucous membrane of the posterior pharynx was much thickened and mamillated.

For relief of the pharyngitis, the first treatment adopted was the application of the nitrate of silver freely to the fauces, at the same time a blister being applied to the sternum, and a tonic mixture, with opium and expectorants, ordered. The

note a few weeks later states that the soreness of the throat and the cough had been much benefited, but that the hoarseness had remained stationary.

It was, therefore, on July 6, after a five weeks' use of the remedies named had failed to effect anything for the chronic laryngitis, that the iodine paint was first employed. A week later the voice was already much improved, and after eight successive paintings the hoarseness was almost gone.

On Sept. 14, the man is described as almost well, his voice being nearly clear. Nine applications of the iodine had now been made. He soon afterwards ceased to attend, and was lost sight of.

The following case afforded one of the most marked examples of the efficiency of the iodine treatment which we recollect to have witnessed.

*Case 11.—Chronic catarrhal laryngitis.—Aphonia of eighteen months' standing.—Rapid cure by the iodine treatment.*—Alfred Oliver, aged 32, a watchmaker, was admitted, under Dr. Risdon Bennett's care, on June 16. He was a well-nourished man, but of pale complexion. His voice was a hoarse whisper, which became slightly ringing on effort to raise it. He stated that the affection had commenced with a severe cold eighteen months before, and that he had never since had his voice. A great variety of treatment had been adopted, but without benefit, excepting that on one occasion he had been much relieved by the use of a tartar-emetic ointment to the throat. No paroxysms of dyspnoea had ever occurred, nor was there any pain or soreness in swallowing. No history of syphilis could be obtained. The Surgeon who had previously attended him, and who took a great interest in the case, stated that he had given him a long course of iodine internally, and had also used blistering to the throat, without obtaining any permanent results. Dr. Bennett ordered the application of the iodine solution, and prescribed a draught, containing tincture of squills and iodide of potassium (gr. iij.), to be taken three times daily.

The application was made very freely, and over a large surface. It produced intense pain which lasted several hours. On the third day afterwards, the man could speak almost clearly, and better than he had ever been able to do for eighteen months before.

Three applications of the iodine were subsequently made on different parts at intervals of about four days. Several slight relapses took place, and the voice continued for some time a little husky. On July 7 the note states, "The voice is now nearly as clear as natural; he can speak out loudly, but occasionally there is a slight degree of roughness. The solution is not to be further used."

On August 7 he was discharged, not having suffered any degree of relapse whatever since the last date.

That the satisfactory result in this case was due rather to the external than the internal medication seems probable, both from its rapidity, and from the fact that similar remedies had previously been employed internally without advantage.

*Case 12.—Acute laryngitis, afterwards lapsing into the chronic form, with evidence of much obstruction.—Mercurial and iodine treatment.—Great benefit.*—Samuel Watts, aged 53, was admitted under Dr. Risdon Bennett's treatment, on June 29. He stated that up to the preceding October he had been quite well, and that he then caught a severe throat affection from being out on a cold foggy night. On arriving at home he felt very ill and at once sent for a Medical man, who told him "that he had croup." He was confined to bed for two months, and not expected to recover. Since then he has slowly improved in health, but has never regained his voice.

His state on admission was as follows:—Breathing difficult, so much so as to oblige him to walk very slowly. Voice exceedingly hoarse, and attended by a distinct laryngeal twang, which was much increased on forced effort and during cough. He complained of much sense of obstruction in the throat, and had some difficulty in swallowing. He was still moderately stout, and had no symptoms of pulmonary disease. It did not appear that he had ever been salivated for the original affection. Dr. Bennett prescribed a squill pill with a grain of blue, to be taken every night, and a draught containing squills and a minute dose of tartarised antimony three times a-day, and also directed the free application of the iodine paint.

No improvement was noticed after the first painting, and a second more severe one was made on July 6.

On July 13 the note is, "Breathes more easily, and can speak and walk better, but still has pain in swallowing."

On the 20th the iodine was again applied, the note on that date being, "Much better, but voice still metallic."

27th.—Voice much softer, and increased in loudness, never, however, quite clear. It has lost its ringing character. He states that he can walk twice as fast as he could. Feels better, and is gaining flesh.

September 14.—Now "feels as well as ever he did in his life." The solution has been applied three times since last note, and the saline mixture has been exchanged for one containing quinine and iron. He states that the sense of obstruction in his throat has been entirely removed, and that whereas it took him two hours to walk from his home to the hospital before the treatment, he now accomplishes it in twenty minutes.

October 26.—He is discharged to-day, being quite well in all respects, excepting a liability to slight thickness of voice at times.

(To be continued.)

## THE ROYAL OPHTHALMIC HOSPITAL.

### SUDDEN FAILURE OF SIGHT DURING LACTATION. —OPHTHALMOSCOPIC EXAMINATION.

(Case under the care of Mr. CRITCHETT.)

Cases of functional amaurosis in connexion with asthenia lactantium are not very infrequent. Feeble mothers not rarely are compelled by the threatened loss of eye-sight to desist from suckling. In these usually both eyes are affected. There have commonly been premonitory symptoms, such as muscæ, and with the restoration of health the affection is mostly in a good degree recovered from. Quite distinct from these, though acknowledging the same cause, are certain cases of far greater infrequency, in which during lactation, usually soon after delivery, the sight of one eye is suddenly and permanently lost. On Tuesday last a woman, aged 26, presented herself amongst Mr. Critchett's out-patients at the Moorfields Hospital, affording a good example of the latter. She stated that she was now within two months of her confinement, and that having lost the sight of one eye after a former one, she was anxious for advice as to any precautionary measures, and more especially as to whether or not she ought to again attempt to nurse her infant. She was very tall, and though of florid complexion, yet of much delicacy of aspect. It appeared that after her second confinement, in January of last year, she had been very weakly indeed. Suddenly, one morning during the seventh week, she found that she had lost the sight of the right eye. For more than a week she was totally blind with it, but afterwards a slow improvement took place, and she is now able to perceive large objects dimly. Her medical attendant insisted upon the infant being weaned when the amaurosis was discovered, and she gradually afterwards regained her health. There had never been any pain in the eye-ball, and the other eye had always retained its function perfectly. On hearing this history Mr. Critchett observed, that in this class of cases, according to his experience, the cause of the failure of sight was almost always extravasation of blood either on or behind the retina. He had seen numerous examples of its occurrence soon after delivery or during an exhausting lactation. In the present case the unassisted eye could discover nothing in the affected organ different from its fellow. The pupil was round and mobile, and the globe had a normal degree of tension. Atropine having been used, the pupil dilated to a large size, with some little improvement in sight. With the ophthalmoscope it was seen that a filmy coloured membrane of considerable size floated in the lower half of the eye, at a little distance from the retinal surface. Only one half of the entrance of the optic nerve could be seen, the other being covered from view by a crescentic patch of what was probably extravasated blood. The condition thus closely coincided with what had been expected. The woman was of course advised not to think of nursing again, and also that after her expected delivery the greatest attention should be paid to the speedy restoration of strength by the early use of liberal diet, etc. The theory of the connexion between general debility and loss of nervous function is much more easily given than that of that between debility

and the local extravasation of blood. Why such extravasation should occur by preference in the eye is also not very easily explained. The clinical fact, however, seems well established. Such cases are of course from the first hopeless as to complete cure, though, as the above proves, a certain degree of improvement may not unfrequently result.

## HOSPITAL NOTES.

### LARGE POPLITEAL ANEURISM, TREATED BY PRESSURE AND AFTERWARDS BY LIGATURE.

An interesting case of aneurism is now under Mr. Birkett's care at Guy's Hospital, which exemplifies a class in which the compression plan often fails. For success that method evidently requires a certain amount of vigour on the part of the patient, and of good coagulating power on the part of the blood. We have had to record many instances of failure in feeble, poor-blooded persons, and the following adds another to the list. A labouring man, giving his age as 36, but looking much older, was admitted with a very large popliteal aneurism in the right ham. He stated that he had continued at work until the previous day, and did not think that the tumour had existed for more than six weeks. The contents of sac appeared to be wholly fluid blood. The pressure treatment was commenced, and persevered in with some interruptions, for twelve days, but without producing any appreciable alteration in the contents of the sac. The integuments on the outer side of the tumour had, however, become discoloured, and Mr. Birkett was apprehensive that ulceration of the sac was impending. It was accordingly determined not to delay longer the placing of a ligature on the femoral artery. This was done at the usual site. The ligature came away on the ninth day, and the wound healed well. It is to be noticed that the diminution in bulk of the tumour appeared to be solely by absorption of fluid blood, and not by any process of solidification. The sac, indeed, although much smaller, is still soft, and contains much fluid blood. The man's general health has much improved since the operation.

### MALIGNANT TUMOUR NEAR THE BREAST AT AN UNUSUALLY EARLY AGE.

When malignant growths occur to persons young in years, it is well known that they are usually either of the medullary or melanotic form, very rarely scirrhous, and with still greater rarity epithelial. In some instances, however, and especially in or near the mammary gland, a form of very dense medullary is met with which approaches closely to the characters of scirrhus. Of this the following is an example:—A delicate, pale-faced girl, aged 23, unmarried, was admitted into St. Bartholomew's, under Mr. Lawrence's care, with a tumour the size of an egg situated in the outer and upper part of the left breast. The skin over it was ulcerated in several parts, and was tense, thin, and shining. Hemorrhage had several times occurred from the ulcerated spots. None of the axillary glands could be ascertained to be enlarged. There was no history of hereditary tendency to malignant diseases. She attributed the tumour to a blow she had received on the part about a year previously. Mr. Lawrence excised the mass, which was found not to be connected with the mammary gland itself. On making a section of it, its lower part was found of great firmness, almost as much so as if true scirrhus, while in its upper were several cysts, containing a bloody fluid. The wound slowly healed, and the woman's recovery was somewhat tedious.

### EXCISION OF THE ANKLE-JOINT.

This operation was performed last week by Mr. Hussey, at the Radcliffe Infirmary, Oxford. The patient was a countryman, aged 26, suffering from disease of the ankle-joint, the origin of which he attributed to a sprain. The malleoli, with the ends of the tibia and fibula, were removed with cutting pliers, and the articular surface of the astragalus was cut away with a gouge. No tendon was divided, and no vessel needed tying.

### COLLODION AND CASTOR-OIL AS AN ARTIFICIAL CUTICLE.

The mixture has been used of late with success in King's College Hospital, as an application to burns and abrasions, to

form a sort of artificial cuticle. It has been used at the suggestion of Dr. Savage, at the Samaritan Hospital, in two cases of vesico-vaginal fistula, now there under the care of Mr. Spencer Wells. In one of these cases there is a recto-vaginal fistula also. In both the excoriation of the labia, perineum, and thighs, from the constant dribbling of urine and the consequent smarting, has been very distressing. Extreme cleanliness, careful drying of the parts, and the use of simple ointment, afforded but little relief. The mixture of one part of collodion to two parts of castor-oil was therefore used, and gave the most marked relief. It causes some smarting for a few minutes after its application, but it then forms a smooth, elastic coating or varnish, which resists the action of the urine for many hours, and effectually protects the excoriated skin from the irritating fluid.

SATURDAY, JANUARY 30.

## MIDWIFERY MALPRACTICE AT MAIDSTONE.

IN our number of the 16th of January we alluded to an investigation which was in progress before a Coroner's jury concerning the death of a woman who had been attended in childbirth by two practitioners, one of whom was unqualified, and the other had been in practice before 1816. The inquiry has now terminated in a verdict of manslaughter against both the practitioners alluded to, namely, Mr. Baldwin and Mr. Ayerst; but the latter, who is an aged man, appears to have had but little connexion with the unfortunate proceedings which resulted in the woman's death, having taken no active part in the operations which were performed.

From the evidence adduced at the Inquest it appears that the woman was advanced about four or five months in pregnancy, and that she was suffering from retroversion of the uterus. It is very difficult to determine the exact nature of the symptoms or of the appearances presented at the period now referred to, because almost the only evidence on these points is that given by Baldwin himself, who does not seem to have had any very clear notion of the anatomy of the parts, and who, moreover, was interested in not giving any testimony to criminate himself. From all we can learn, however, we conclude that the uterus was retroverted, the bulk of the organ filling the cavity of the pelvis, and the os uteri pushed up behind the symphysis pubis. The woman seems to have suffered from retention of urine, caused by the pressure of the retroverted uterus upon the neck of the bladder; but with this exception, her sufferings were not remarkable, and although there can be little doubt that she was seized with the pains of premature labour, there is no very definite information upon this point.

Under these circumstances, the woman's sister applied to Mr. Fry, a surgeon of repute in Maidstone, and having described the symptoms, she received for the patient some medicine, consisting of a little opiate with some diuretic. Mr. Fry himself visited her on the same afternoon, and found

her in a room standing before the fire. She said she was easier since she had taken the medicine, and that her chief difficulty was in passing her water. This visit was made about four o'clock in the afternoon of the 28th of December last, and at about eight or nine o'clock the husband applied to Mr. Fry to come again and see his wife, but that gentleman was engaged and could not see him; and although the man appears to have called a second time, Mr. Fry was unable to attend to him. Here we must remark that it was a most unfortunate circumstance that Mr. Fry made no examination of the uterine organs on his visit; and his inability to attend the patient when he was sent for was still more unfortunate, for the result was, that the husband, in his natural anxiety for the safety of his wife, having failed in his endeavour to procure legitimate assistance, may have been, and probably was, forced to accept such services as he might find to be available.

Mr. Baldwin, therefore, comes upon the scene, and upon his arrival he was duly impressed with the serious nature of the case, and indeed expressed his anxiety to have nothing to do with it, as he thought it would terminate unfavourably whoever undertook it. But the mother of the patient urged him to stay, which he at first declined, but eventually he consented to remain if further advice were procured. Accordingly Mr. Ayerst, the other person implicated in the proceedings before the Coroner, was sent for, and he attended; and in conjunction with Baldwin he undertook the management of the case. We are now told that Mr. Ayerst advised the use of instruments, and that Baldwin went and procured them.

At this point the doubts and difficulties of the case begin to arise, because it is not at all clear why the use of instruments should have been recommended. Supposing the case to have been one of retroversion of the uterus, it seems to be little short of insanity to employ the forceps for its rectification; and another serious question arises, whether the clumsy use of these instruments did not cause the rupture of the womb, of which the woman soon afterwards died. Here, however, the evidence is incomplete, for while the Medical witnesses express a very strong opinion that the rupture was produced by the instruments, Baldwin, on the other hand, endeavours to show that the rupture existed before he was called in. The great improbability of such an occurrence was strongly insisted upon by the Medical witnesses, none of whom had ever known of a case of ruptured uterus in the fourth or fifth month of gestation, and we believe that the majority of the Profession will join in the feeling of incredulity thus expressed. Still it must be admitted that there is no positive evidence to contradict the assertion of Baldwin, that he found a rupture on his arrival. In his own voluntary statement made before the Coroner he alleges that he found the uterus forced down and impacted, and tilted either backwards or forwards; that he could not find the os uteri, but opposite the symphysis pubis he found a partial rupture of the walls of the uterus, and was fearful of replacing that organ by the least exertion of force, lest he should produce a further rupture. On the arrival of Mr. Ayerst, he states that he informed that gentleman of the existence of the rupture, and was advised by him to have recourse to instruments; that he accordingly brought them, and under Mr. Ayerst's directions applied the forceps, or rather one blade. "I could not," he says, "make the other enter; and not understanding anything of the case, I did not like to use them any further. Mr. Ayerst then said I was to try the perforator, and I inserted the perforator through the rupture, where I felt something soft, like the membrane containing the liquor amnii, which then escaped; and I then put in the blunt hook, and extracted the fetus feet foremost. I put my hand upon the abdomen, and found it very much distended, but it soon subsided; and upon

bringing my hand down, I found the womb *through the vagina* (?), and into the world. I called the attention of Mr. Ayerst to the circumstance, and he replaced it; and having introduced a piece of sponge into the vagina, applied a bandage to retain it in its place."

It cannot be a matter of surprise that the patient soon died after this treatment; and on the post-mortem examination of the parts, it was ascertained that the os and cervix uteri were perfectly natural, a large bougie being easily passed through the os into the cavity of the uterus. At the back part of this organ there was a rent two inches long, and there was a corresponding rent in the vagina; these lacerations being attributed by Mr. Gorham, one of the Medical witnesses, to the improper and unnecessary use of instruments, although, according to the statement of Mr. Baldwin, the lacerations existed before the instruments were applied. Mr. Gorham further expressed his opinion that there was nothing in the case to induce him to believe that it would not have done well under proper treatment; that he was not aware of any instance where instruments had been used at so early a period of gestation; and that their employment, under the circumstances described, was unjustifiable and cruel, the woman having lost her life most probably in consequence of the interference.

Our own opinion of the case is, that it exhibited gross mismanagement, and was a very proper subject for judicial investigation. Supposing the case to have been one of retroversion of the uterus (which we believe it to have been); attended with difficulty of making water and retention of urine, the proper method of treatment would have been to relieve the bladder by the introduction of the catheter, and by manual efforts to replace the uterus in its right position, and the labour would then, no doubt, have terminated favourably. The introduction of the forceps, the perforator, and the blunt hook, appears to have been perfectly indefensible.

We are unwilling to enter further into the details, because two persons have now been committed to take their trial on the charge of manslaughter in connexion with the woman's death, and any further remarks we may have to offer will come with more propriety after the trial has taken place.

But in the meantime we must again express our surprise and indignation that the Legislature should still permit persons without any Medical qualification to practise upon the ignorant and the unwary, to the great discredit of Medical science, and the great injury of the public. A person who introduces a pair of forceps, a perforator, and a blunt hook into a woman's uterus, without knowing the use of those instruments or the anatomy of the parts to which they are applied, is in our eyes quite as much guilty of a crime as a person who robs a passenger upon the highway. These remarks will not prejudice the prisoner Baldwin, because, judging from experience, we anticipate that his ignorance will rather be an argument in his favour than otherwise.

#### THE WEEK.

THERE are few classes of the London population who suffer more from street nuisances than Medical men. In many neighbourhoods the morning consultations with patients are interrupted—the sounds of the heart and lungs are inaudible through the din of brass bands and organ-grinders—and in the evening, study or writing are out of the question—while quiet for patients is unattainable. The Belgians have petitioned Parliament on the subject, and the Paddingtonians have appointed a committee to communicate with other parishes to obtain the assistance of the Legislature. The resolution carried at the Paddington meeting,—“That in the opinion of this meeting the noises from itinerant musicians,

newspaper vendors, bawlers and hawkers, daily and nightly occurring throughout the streets of this parish, are intolerable nuisances, and demand the immediate intervention of the authorities,"—is undeniably true, and we heartily wish success to the committee in their endeavours to abate the nuisance.

Dr. George Buchanan, of Glasgow, has just published a pamphlet on the Anatomy Act, and the facilities for the study of Practical Anatomy in Glasgow, which contains a very interesting account of the difficulties under which teachers and students laboured before Mr. Warburton's Act was passed. One passage we must quote, as it contains some practical details of the adventures our London students will probably engage in before long, if subjects cannot be procured in a more legitimate manner. It appears that there were no professed resurrectionists in Glasgow, so that the onus of supplying the dissecting rooms rested with the teachers and students. The mode of procedure of these gentlemen is thus described by Dr. Buchanan:—"The grave of a recently buried body was carefully observed and marked during the day, and a band of a sufficient number—usually four or six—was made up. The party, provided with a dark lantern, an old carpet, a sack, and shovels and pickaxe, took the advantage of the first dark, cloudy, perhaps windy night, in order that their proceedings might be the better concealed. Sentries were posted to give notice of any alarm which might get up, and the principals entered the graveyard by climbing the wall, at a distance from the gate. The grave was then opened to about half its extent, and by dint of hard labour, about one-third of the coffin-lid was exposed. The strongest of the party now entered with the lantern to perform the most difficult part of the whole, and over the open grave was thrown the carpet above mentioned, for the double purpose of concealing the light and deadening the noise of the working. The coffin-lid was wrenched open by a short crow-bar, and, by sheer force, was broken off where it remained covered with earth. The noose of a strong rope was now put round the neck of the body and handed up to the others outside, who soon pulled up the corpse to the surface. It was then wrapped up in the sack, and carried off to a convenient place, and the grave was filled up and covered, great care being taken to leave the surface as near as possible in the same condition in which it was found." Joking apart, it is quite evident that if the teachers do not bestir themselves, stir up Sir George Grey, and make Sir George stir up the Inspector of Anatomy, the teaching of practical Anatomy and operative Surgery in London will soon become a thing of the past, and our lecturers will be reduced to teach from plates and diagrams, and demonstrate the operations of surgery on dead dogs.

If anything were wanted to confirm the accuracy of the view we have taken of the case of Mr. Symes and the Poor-law Guardians at Bridgewater, it would be supplied by the fact that a testimonial has been presented to Mr. Symes, signed by 624 of the poor inhabitants of the town, conveying to that gentleman the assurance of the confidence they repose in him, and the kind regard in which he is held.

The *Gazette des Hôpitaux* contains a short account of the wounds received in the murderous attack on the Emperor Napoleon on the 14th instant. Most of the wounds were light, but many persons had a great many wounds, one as many as twenty-seven, and these became very irritable after a few days. One person died with a large piece of shell in

the abdomen. The bombs or grenades were filled with fulminating mercury, instead of gunpowder, and to this cause M. Larrey attributes the number and slightness of the wounds, the power of the fulminating powder being so great as to shiver the grenades to atoms, instead of bursting them into large pieces as gunpowder does.

It appears from the last weekly return of the Board of Health that scurvy still prevails to an extent not inconsiderable in our mercantile marine. The Merchant Seamen's Act requires that after a certain number of days at sea, half an ounce of lemon-juice should be given to each man daily, but this is not at all strictly attended to. At the Dreadnought Hospital-ship there have been several cases lately, not only from ships from India, but also from coasting vessels. Scurvy is almost unknown in our navy and convict ships, and it is the fault of the owners and captains if it appear in merchant vessels. We may observe, however, that as lemon-juice is only kept with difficulty, it would be well to allow these vessels to take citric acid and potass instead, which experience in the navy has shown to be quite as effectual as the fresh lemon-juice in preventing scurvy.

The Treasurer of the Medical Benevolent Fund has lately put forward an urgent appeal for pecuniary aid; an appeal which we earnestly hope will not be made in vain. The principles on which the Medical Benevolent Fund is administered differ very widely from those of most other charities: the working expenses are very small, the relief afforded is prompt, the proceedings are carried on without publicity, and canvassing is wholly superseded. The Committee meet at stated intervals in a Committee-room granted to them free of expense, by the kindness of Mr. Churchill; urgent cases of distress are immediately relieved by a pecuniary grant as far as the funds will permit; the names of the recipients of such bounty are known only to the Committee; and the fatigue, anxiety, uncertainty and expense of a canvass for votes are entirely avoided. There are seventeen annuitants of the Fund, six of whom are also provided with comfortable homes at Chippenham; but besides these cases, relief is annually afforded to such urgent cases as are brought before the notice of the Committee. As a proof of the beneficent operation of the Fund, the Treasurer has published a paper containing the minutes of the proceedings of the Committee at their meeting last November, with the details of the cases, though without the names, then relieved. The twelve cases thus recorded exhibit a heartrending picture of the miseries endured by some of our unfortunate Professional brethren, their wives and children, and we deeply sympathise with the regret expressed by the Committee that the grants afforded were so inadequate to the necessities of the applicants. We hope that the opening of the new year may usher in a greater degree of prosperity than the Medical Benevolent Fund has yet attained, and that, by the kindness and liberality of the Public as well as of the Profession, the sphere of its operations may be extended so as to embrace a much more numerous class of deserving objects, and to confer greater benefits than it has hitherto been able to bestow from its limited resources.

The Manchester and Salford Sanitary Association have published an annual Return of Mortality in the Townships within the Borough of Manchester and Salford for the year ending September 30, 1857. In this interesting document, it appears that the deaths from all causes in these localities show a slight increase (.06 per cent.) upon the return of last year; but a diminution of .43 per cent. as compared with

1855. The deaths from Fever, Scarlatina, Measles and Small-Pox are specially enumerated, and are found to have diminished in the proportion of 12·57 per cent. in 1855, to 8·8 per cent. in the last year: the deaths from Fever have slightly diminished, but those from Scarlatina have considerably diminished, namely, from 7·84 per cent. in 1855 to 3·82 per cent. in 1857. But the deaths from Small-Pox, we regret to find, have considerably increased, being in 1855 ·08 per cent. and in the last year 1·16 per cent., a result no doubt attributable to the great laxity of the present system of conducting vaccination. Mr. Royston, the Deputy Treasurer of the Association, has published upon a separate Chart, a tabular statement of the variations of Scarlatina in the different towns included in the Manchester and Salford districts, extending from March 1854 to September 1857, and marking the highest and lowest points reached by the epidemic in the several localities in the respective months. The total deaths from Scarlatina during the period in question amounted to 2672, or at the rate of 5 per cent. per annum on the total mortality. Great praise is due to the Association and to Mr. Royston, for the able manner in which these tabular statements have been drawn up.

### REVIEWS.

*On the Introduction of the Sponge-armed Probang into the Larynx and Trachea.* By HORACE GREEN, M.D. LL.D. 8vo, pp. 14. New York: 1857.

*Lesions of the Epiglottic Cartilage.* By HORACE GREEN, M.D. LL.D. 8vo, pp. 28. New York: 1857.

Dr. Green is well known to the Profession as the advocate of topical applications in diseases of the larynx and trachea. Much scepticism, nevertheless, prevails as to the possibility of reaching parts so vigilantly guarded against intrusion. It is the object of the author in the first-named pamphlet to prove that the probang can really be introduced, and this he has undertaken in the face of high authority in favour of a contrary opinion. Trousseau declares the introduction of the sponge probang into the larynx to be impossible even in the dead subject. Mr. Erichsen, who has given the subject much attention, admits that the sponge may be passed into the glottis in the living subject, but not between the vocal chords. Names of eminence might certainly be cited on the opposite side, and we have long been of opinion that the operation is in some cases quite practicable. We say *some*, because we have more frequently found the sensibility of the parts so exalted as altogether to preclude it.

In proof of his position the author gives a detailed account of certain experiments performed in the presence of several Medical men. The following is a summary of the most important of these experiments.

A sponge probang having been introduced into the larynx, a second one was passed rapidly into the œsophagus.

In cases of stricture of the œsophagus in which the sponge probang could not be passed below the stricture, the instrument was passed into the trachea some inches further.

A catheter was introduced several inches into the trachea, and a lamp was extinguished by the patient blowing through the tube.

In a case of cut throat, Dr. Green was successful in causing the probang which had been passed through the larynx, to appear at the opening in the trachea. It should be stated that in several similar cases Mr. Erichsen constantly failed in effecting this.

A piece of wire was passed upwards through a fistulous opening in the trachea, the result of operation—while the sponge probang, charged with a solution of nitrate of silver, was passed downwards through the larynx. The meeting of the sponge with the wire was distinctly felt, and the latter was found to have been blackened by the caustic.

The pamphlet on "Lesions of the Epiglottic Cartilage," more correctly of the epiglottis, contains some curious statements. These lesions the author divides into—

1st. Erosions or abrasions of its mucous membrane.

2nd. Ulcerations of the membrane and of its glands.

3rd. Œdema, or infiltration of its areolar tissue.

Speaking of the first of these, Dr. Green says:—

"On depressing the tongue in such cases, by means of the ordinary bent spatula, or 'tongue depressor,' so as to bring the epiglottis into view, this cartilage has been found frequently inflamed, vascular, and its superior border marked at one or more points by distinct erosions. In much the largest proportion of cases, these erosions make their first appearance in the left superior edge of the epiglottis. Next in frequency they will be found occupying its centre; and occasionally, but very rarely in comparison with the two preceding locations, they have been observed on its right border. These erosions are not readily detected at first by the inattentive observer; as they are quite small, are only slightly depressed, with a pallid base, sometimes a little reddened, and with whitish linear edges."

No explanation of the preference exhibited by these lesions for the left side of the epiglottis is attempted. An essential distinction is drawn by the author between erosion and ulceration of the mucous membrane of the epiglottis. He states that he has never observed the one to pass into the other.

Louis regarded erosion simply as the first degree of ulceration. He speaks only of the latter, while from his descriptions it is plain that he had noticed the appearances said by Dr. Green to be caused by erosion. It is worthy of remark that Louis regarded the laryngeal ulceration so common in phthisis as the result of the passage of tuberculous matter over the mucous membrane. In this way he accounted for the greater liability to be affected of the posterior part of the larynx and inferior surface of the epiglottis.

Œdema of the glottis, Dr. Green says, is always confined to the lingual surface of the epiglottis: "there being no areolar tissue whatever interposed between the membrane and this cartilage on its laryngeal face, consequently in Œdema of this organ the infiltration of fluid must take place on the lingual surface."

The treatment mainly relied on in all the foregoing cases, is the topical application of nitrate of silver, either in the solid form, or as a strong solution. Apropos of treatment; there is an amusing anecdote of homœopathic practice related by a gentleman who consulted Dr. Green for ulceration of the larynx, and had been for a long time under the care of an homœopathic practitioner. "Finding that no effect was produced on the disease, he finally informed Mr. B. that such was the peculiar character of his disease, that it could not be influenced by homœopathic notions, and that the nature of the disease must be *changed*. He therefore advised Mr. B. to *contract syphilitic disease*, and await its secondary effect—the occurrence of ulcers of the throat; that these would eradicate his present disorder, and that homœopathy, in turn, would find no difficulty in expelling from his system the syphilitic disorder."

Whether or not Mr. B., who "is still living, and will bear testimony to the above statement," acted as directed by the knavish or ignorant, but, in any case, immoral globulist, is not stated.

We extract some interesting physiological and anatomical remarks:—

"With those physiologists who have been accustomed to consider the integrity of the epiglottis as being essential to the perfect act of deglutition, this may be an interesting inquiry, How far are the functions of this organ interfered with by the lesions we have described? Ordinarily, neither erosions nor ulcerations of the border of the epiglottis will increase, to any extent, the difficulty of deglutition. Two cases have come under my notice, in each of which the epiglottis of the patient was entirely destroyed by œdema and ulceration; and yet, in both instances, these patients, after a few weeks, could swallow, either solids or liquids, without the slightest inconvenience. In both these instances the destruction of the epiglottis was caused by ulceration, following extensive œdema of this organ; a condition which supervened upon a constitutional syphilitic taint. In the first instance I did not see the case until the epiglottis was nearly destroyed by ulceration.

"What, then, is the special function of the epiglottis if its presence is not absolutely necessary to the integrity of deglutition?"

"The arytenoid muscles are the especial constrictor

muscles of the glottis, and most physiologists have asserted that these muscles receive their nerves from the superior laryngeal; but M. Longet has demonstrated that they are supplied with filaments from the recurrent nerve, and that the mucous membrane covering the lips of the glottis, or the supra-glottic vestibule, in which is located that exquisite sensibility which is disturbed by the smallest drop of fluid, or the contact of any foreign body,—that this space receives its filaments from the internal branch of the superior laryngeal nerve.

"These two nerves communicate freely with each other, but they have no connexion with the epiglottis, consequently the application of irritants to this body will have no influence upon either the motor or sentient nerves, peculiar to the larynx. But when the irritation of the sensitive mucous membrane at the entrance of the glottis occurs, it is quickly transferred to the constrictor muscles of the larynx. It is therefore not correct to state, as many anatomists do, that the epiglottis itself 'closes completely the opening of the larynx' in deglutition."

Dr. Green certainly appears to have satisfactorily proved his position, that it is possible to introduce a sponge-armed probang into the larynx. As to the beneficial results to be thus obtained from the application of solutions of nitrate of silver, there can be no question. The pamphlet on Diseases of the Epiglottis may be read with much advantage. It forms a sequel to the author's other writings on the Treatment of Diseases of the Larynx and Trachea.

*The Effect of Climate on Tuberculous Disease, being (with additions) the Essay for which the Fiske Fund Prize was awarded to EDWIN LEE, M.D. With an Appendix of Corroborative Observations and Notices of several Places of Winter Resort.* Pp. 223. London: 1858.

THE curability of consumption is a problem which has engaged the attention of the Medical Profession for a great number of years, and it cannot yet be considered as definitely solved. Dr. Edwin Lee, however, tells us that its curability can no longer be reasonably questioned, although the proofs which he adduces in support of this assertion are somewhat feeble. In fact, he does not quote cases or statistics in which the existence of the disease has been accurately determined in its origin, its progress, and its cure in the living individual, but he merely records the necroscopic observations of Laennec, Cruveilhier, and others, who have described certain scars often found in the lungs of the dead, and which are assumed to be the evidences of preceding tuberculation. That this is possibly the case may be admitted, but the connexion of these scars with the positive evidence of tubercles in the living body remains yet, we think, to be proved. Dr. Lee affirms that the chief obstacle to the curability of consumption is to be found in the incompetency of British practitioners to detect the malady in its early stages, owing to the neglect which exists in teaching auscultation and percussion to Medical students in this country. As Dr. Lee thus severely criticizes the diagnostic skill of his Medical fellow-countrymen, we might reasonably expect that he would furnish us with a few hints as to the means of a better and more accurate exploration of the chest than is at present practised; or at any rate, that he would relate a few cases coming under his own observation where the physical signs were duly recorded, and the progress of the disease was carefully watched. But we can find no such information in the essay before us, which consists of a great number of quotations from other authors, principally French, on the influence of climate in producing disease; together with some general judicious remarks upon the effects caused by different localities upon Tubercular Phthisis. In the conclusions drawn by Dr. Lee, and presented in a tabulated form at the end of the essay, we should be inclined to join; and it is clear that he has taken great pains in collecting together much valuable information; but, as we have just remarked, we should feel better satisfied if the cases on which the conclusions have been drawn were more clearly defined and explained.

When we have stated that Dr. Edwin Lee's essay adds nothing to our existing knowledge of the pathology of Tubercular Phthisis, our chief objections are expressed. In other respects Dr. Lee's book is very readable, and the precepts it contains are drawn from considerable experience of books and localities. The volume concludes with a few notices of some

of the most frequented places of winter resort, which portions are written in Dr. Lee's usual agreeable style, and though necessarily discursive, they contain much information upon a variety of points likely to be interesting to the invalid who is travelling in search of health.

*The Hygiene of the Turkish Army.* By J. N. RADCLIFFE, M.R.C.S. Eng., late of the Staff of H.H. Omar Pasha. Pp. 60. London: 1858.

IN these pages we find a great amount of information upon the clothing, diet, and habits of the Turkish soldiers, derived from the personal observation of the author while he was attached to the Turkish army. In many respects it is shown that the Turkish soldier is better cared for by his Government than his British comrade; and in particular, it appears that he receives more solid food, and is prohibited from the use of alcoholic liquors. On the other hand, the personal habits of the Turks are very objectionable, and their negligence of the ordinary rules of cleanliness and propriety must have fostered the continuance of disease during the Crimean war. Indeed, not only the Turkish army, but the French and Sardinian also, contrasted most unfavourably with the British during that memorable contest; and the evidence of the senses alone was sufficient to distinguish the British camp from those of their allies. The physical condition of the Turkish soldier is considered by Mr. Radcliffe to be very favourable to the services in which he is engaged, his robust and mature frame and his temperate habits enabling him to encounter a degree of fatigue and privation which are too often fatal to the undeveloped bodies of the British recruits, of whom our army in the East was in great measure composed. The state of Medical education among the surgeons of the Turkish army appears to be very low; and the Medical and surgical treatment of the sick and wounded soldiers is conducted in a very inefficient manner. The Turkish medical men are usually educated at Constantinople or at Alexandria; but those who are attached to the army are Germans, Hungarians, Italians, Frenchmen, and others, some of whom have been well educated in their respective countries; but some have received very little education, and many none at all, being mere adventurers without any qualifications. The supply of instruments and drugs is also most inadequate, owing to the well-known dishonesty and ignorance of the commanding officers, to whom, and not to the Medical staff, is most improperly entrusted the charge of furnishing those appliances.

## PROGRESS OF MEDICAL SCIENCE.

### Selections from Foreign Journals.

#### ON THE GLYCEROLE OF ALOES IN LICHEN AGRIUS.

By M. CHAUSIT.

"THE rational study of diseases of the skin teaches us that they are usually dependent upon a general condition, the modification of which is indispensable for the removal of symptoms that are merely the external sign of this. Therefore, it is always right to say that the employment of general and internal means plays the principal part in the treatment of these diseases. Nevertheless, repeated observations have enabled me to appreciate a point, secondary, perhaps, but yet of importance in practice, viz. that in many cases there is a local condition which exercises a real influence on the progress of the eruption, and calls for local treatment. Thus, in *lichen agrius*, and especially when it is seated in certain spots, the affection becomes complicated with a symptom, due perhaps to conditions peculiar to the tissue of the parts affected, and which tends to maintain and even aggravate the disease. I mean those excoriations and fissures which are especially met with on the skin of the dorsal surface of the joints of the phalanges, of the wrists, and at the bends of the principal joints of the body. If these in some cases are the natural consequences of the progress of the disease, they result usually from manual habitudes, progression, or from certain external impressions—in a word, from the motions themselves involuntarily produced in these regions, by which

the skin becomes thickened and rugose, loses its natural suppleness, and easily tears and breaks under the influence of the incessant tractions to which it is subjected. So true is this, that I have been able to remove this condition whenever it has been possible to render the part affected immovable, without causing too much trouble and constraint to the patient, which, however, is rarely the case in practice."

The author cites a case in point, of a washerwoman, who had suffered for about six weeks from lichen, complicated with painful fissures confined to the last two fingers, and surrounded by an inflamed skin with violent pruritus. After trying the various topical applications during three weeks, the fingers were kept immovably extended upon a small splint. In four days the bleeding chaps had completely healed, and the hypertrophy and redness of the skin had much diminished; and eight days later all traces of the eruption had disappeared.

The author was led to the employment of *aloes* for the treatment of these troublesome ulcerations, from having observed the remarkable power of the tincture in expediting cicatrization in veterinary practice; and in this paper he relates four cases of *lichen agrius* treated by its agency which yielded in a few days. The following is the formula he recommends:—Tincture of aloes, four to eight parts; heat until the alcohol is completely evaporated, and then gradually add thirty parts of glycerine. This forms a liquid of a mahogany colour, which never becomes turbid or deposits, and which should be applied by means of a pencil. In order to be certain that the good effect really resulted from this application, in a case in which lichen affected both hands, he applied it to only one, and in this hand alone did the improvement take place. The proportion of the tincture must be determined by the effect intended to be produced, and especially by individual conditions whether of the tissue, seat, or nature of the points affected. But in any case local accidents (such as the production of impetigo when used too strong) which the glycerole may give rise to do not prevent the successful results of its application. The author has employed the glycerole with great advantage in a case which seemed to depend especially on constitutional condition, the eruption amending on the healing of the ulcers. Even supposing the latter effect alone produced, the relief of the attendant suffering is a great point gained. Numerous cases have shown that the efficacy of the application is much more decided in *lichen agrius* than in *lichen non agrius*. It was probably due to the essentially "cicatrizing virtue" of the aloes that two cases of *syccosis* of the upper lip, with painful and bleeding cracks at the base of the nares, were relieved by an aloes ointment, composed of one part of tincture to ten of lard. Encouraged by his success the author extended the application of the glycerole to the excoriations from *eczema*, which are analogous to the fissures in lichen, in the condition of their production and the influence they exercise in perpetuating the eruption. In two cases of obstinate *eczema* of the ear, prompt relief followed, and in one of *eczema* of the breast the same effect was produced, but was followed by an angioleucitis from too large a proportion of aloes having been employed. Affections of the *acne* type have also been treated, and thus far with success, although, as the cases are still under treatment, nothing yet can be decisively stated.

The action of the glycerole of aloes essentially differs from that of topical applications employed as astringents or slight caustics, such as lead, zinc, tannin, nitrate of silver. It is a tonic, and in this point of view offers great advantage; and it is prompt in its effect, a few days, at most five or six applications, sufficing to procure the cicatrization of old obstinate fissures, which not only constitute a painful symptom, but become the cause of further extension of the disease. The immediate local effect is that of a smarting sensation, which is not always present, and generally passes off in a few minutes. The glycerine has nothing to do with these favourable results, for in several cases it had been previously employed alone without effect, and comparative experiments point to the same conclusion. It is remarkable that after the employment of this application the tissues have a great tendency to return to their normal condition. The tension and renitence promptly disappear, as does also the thickening of the skin, this tissue recovering all its suppleness, and, indeed, in some cases, acquiring a greater degree of this than it formerly possessed. —*Gaz. des Hôp.* 1857, Nos. 60, 62.

## ON THE TREATMENT OF NÆVUS BY VACCINATION.

By M. NÉLATON.

In a recent clinical lecture M. Nélaton observed, that to reap the benefit of this excellent means of treating nævus, it is indispensable that certain precautions should be observed in putting it into force, the neglect of which has often been the cause of the failures practitioners have complained of. Thus if we vaccinate with the point of a lancet, scarcely does the instrument penetrate beneath the epidermis, when a considerable flow of blood takes place, which carries with it almost all the virus, leaving the operation imperfect. To obviate this inconvenience we should select the finest insect pins, and charging their points with virus taken directly from a child's arm, they should be thrust into the nævus, and allowed to remain there, the flow of blood being thus completely prevented. They should be implanted at short intervals, of half or one centimetre from each other. In a few minutes, when we believe that the tissue has become sufficiently impregnated by the virus, the pins should be withdrawn. The pustules undergo their ordinary development, each puncture becomes indurated and inflamed, and a vaccinal eruption covers all the tumour. The peculiarity in the action of the vaccine virus is that it acts more deeply than most of the caustic modifying agents at our command. The action is propagated to the subcutaneous tumour, and we obtain a cure exempt from all the dangers attendant upon the application of caustics, and without the production of a cicatrix, which in many situations might prove of great inconvenience.

Another mode of vaccinating nævus has been adopted by M. Nélaton in two instances. The first of these was an unvaccinated infant, sent to him by M. P. Dubois, on account of a subcutaneous erectile tumour in the parotid region. He passed in four needles transversely, traversing the tumour through and through, and then passed two vertical pins in the same manner. These six pins were left in for twenty-four hours, and then replaced by threads. The six setons were left in for eight days, and then the vaccine virus was so applied as not to implicate the edges of the wound, which would have given rise to twelve vaccine pustules. The adjoining integuments were to this end protected by very minute fistulalachrymalis canulas slid over each thread. The threads were then impregnated to a certain extent with the virus, and passed through the canulas into the depth of the erectile mass. At the end of four days there came on considerable inflammatory swelling, which lasted as long as the natural period of the vaccine evolution. The tumour then became very hard and compact, the vessels being obliterated. The cure remained permanent, no cicatrix resulting; one of the orifices had been inoculated, and a vaccine pustule was produced. With a little attention, even this slight inconvenience might have been avoided.

We may therefore state that vaccination is a valuable means of treating erectile tumours; but as it requires that the patients have not been previously vaccinated, it is always a good precaution before vaccinating an infant to inquire whether there is not some small erectile tumour in some part of its body.—*Union Méd.*, 1857, No. 63.

## ON THE TREATMENT OF LEAD COLIC.

By M. LEGROUX.

M. Legroux' communication is in the form of a Report on a paper by M. Girard of Marseilles. Lead-colic had been of rare occurrence in that city until 1853, when some metallic works being established, in the working of which lead was incidentally produced, 52 out of 260 work-people became affected within a month. Of these 39 came under M. Girard's care; and of this number one died of cerebral symptoms after his third attack of colic; 2 continued to suffer from paralysis of the wrist; and 7, who had had repeated attacks, exhibited serious symptoms. The others were only slight cases. All manifested changes in the gums, these being fungous and bleeding in some, and showing the blue line in others. The same treatment was observed in all, with the effect of rapidly dissipating the colic. This consisted in the exhibition of a pill containing two drops of croton oil and a senna clyster, and giving a pill every two hours, formed of extract of belladonna and opium, of each 1 grain, divided into 4 pills. The croton oil was continued a day or two, even if the pain were relieved; and the narcotic pills were continued for several days, with the occasional interposition of a purgative. One or two

sulphureous baths terminated the treatment, a few days sufficing for the cure.

M. Girard directs attention to a symptom observed in these cases, which he believes that he is the first to note, viz. a *souffle* furnished by the carotid arteries, and which he supposes to arise from the anæmic condition induced by the absorption of the molecules of the lead, of which the colic is but an epiphenomenon or neuralgic complication. This anæmia he attributes to the fluidifying power of the lead on the globules of the blood; and obstinate constipation with colic is a consequence of such anæmia. Purgatives rapidly relieve this condition, but as long as the anæmia persists relapse may take place, so that the great point is to restore the normal condition of the blood.

M. Legroux observes, that although the carotidean *souffle* may not have been noticed, the existence of anæmia, of which such *souffle* is an usual sign, has been long known and described. M. Girard in directing attention to the necessity of relieving the anæmic condition, has overlooked the principal fact, that a poison has to be eliminated. Tonics, iron, etc., are of no avail for this purpose, while the poison once removed from the blood, the anæmia ceases almost spontaneously. If the treatment adopted by M. Girard proved so rapidly efficacious, it arose from the fact of most of the cases being very slight; and even then relapses must be expected, for a long time is usually required to thoroughly purify the economy even in the simplest cases. The baths with which M. Girard terminated his treatment, are the means with which he ought to have commenced it. Observing, on the one hand, the facility with which cures are announced as rapidly obtained by purgatives and narcotics, and on the other the frequency of the occurrence of relapse, M. Legroux takes the opportunity of laying down the curative indications in *lead poisoning*. This term should be employed in preference to that of *lead colic*, which only indicates one symptom of a serious, deep-seated, general affection, which persists in spite of the temporary cessation of such symptom. It localises in the intestinal canal pain, which perhaps really has another seat, as indicated by the term *rachialgia*. It confounds together affections of the intestines of a most different nature, in consequence of their having pain as a symptom in common; and when this pain is relieved by some simple medication, a cure is supposed to have taken place because the colic has ceased. The patient leaves the Hospital apparently cured, and does not remain long before he is obliged to repair to another, suffering from accidents of a severer character than in the first instance. The colic had been suspended, but the intoxication persisted; and it cannot be too often repeated that the patient must not be considered cured as long as any lead remains in the economy, and that its complete elimination generally requires a long time.

The first indication to be fulfilled is the neutralisation, and especially the elimination of the lead deposited on the surface of the skin and the mucous membranes, or incrustated in their tissue. The black colouring of the skin due to the sulphuret of lead, produced by the agency of sulphureous baths, may often be reproduced three or four times, at more or less prolonged intervals. It has been observed on taking the sixth or seventh bath even, after five or six weeks' treatment. It is then only partial, and is seen especially round the nails. What is observed on the skin, likewise, may be seen on the mucous membranes in the form of altered condition of the edge of the gums, and of the slate colour of the large intestine, notwithstanding repeated purgation. When a patient suffering from lead-poison is brought to the Hôtel Dieu, M. Legroux orders him to be put into a sulphur bath and well brushed with soap. The soap does not suffice without the brush for the detachment of the sulphuret of lead. The patient does not go to bed until after this depuration, so that particles of lead collected on the surface may not become deposited in the pulverulent form, and afterwards be drawn into the mouth during the act of inspiration. In the same way the clothes pulled off should be changed, or thoroughly cleansed. While in the bath the hair, often matted together by the salts of lead, should be especially cleansed. The shoes are also placed in the bath and soaped. These operations are repeated several times at some days' interval, and that even if the last bath has not given rise to any black colour, experience having proved that after disappearing from the skin, the sulphuret may be reproduced there by the fifth or sixth sulphureous bath, and that even when it has not shown itself in the third or fourth. The

depuration of the mucous membrane of the digestive canal is accomplished by more or less strong purgatives, which indeed constitute the base of all modes of treatment—those even in which the curative power is attributed to neutralising agency or narcotics. Purgatives carry off the molecules which are lying free in the canal, and they induce exhalations and secretions of all kinds, by the aid of which the poison incrustated in the mucous membrane becomes detached, while that which has been introduced more deeply by absorption becomes eliminated. But one or two purgations will not effect complete depuration; and we must often repeat them during one or two weeks, recourse being still had occasionally to the same means during convalescence.

In respect to neutralising agents, M. Legroux regards sulphuric acid, sulphureous waters, and alum as useless, if not mischievous; but he thinks the persulphate of iron may be of some utility, given in subordination to purgatives. We have seen how long a period is required to produce complete cleansing of the skin, even with the aid of soap and the brush; and it may be supposed that a still longer time is necessary for the depuration of the intestinal canal. How often it has happened that patients cured to appearance have fallen ill again after some days of convalescence! It is by no means rare to find in workers in lead, who have undergone the Charité purgative treatment even two or three times, just when the cessation of all pain, and the return of strength and natural colour seemed to announce a certain cure, pallor return, the appetite lost, and a relapse taking place. All the lead had not been eliminated. It had remained latent in the economy, incorporated with the tissues or circulating in the blood. The elimination of the absorbed lead is a slow and difficult process, requiring frequent recourse to evacuates and sulphureous baths. M. Legroux has had no personal experience with the iodide of potassium, but it has proved of benefit in the hands of his colleague, M. Guillot.

At least two or three weeks are required for the internal and external depuration in lead poisoning; and supposing that within this space of time we have succeeded in eliminating all the poison, at least as long a period is required for the strengthening of the economy, purgatives and sulphureous baths still being occasionally required during this latter period. We must not consider a patient cured until a considerable time after the disappearance of all pain and of the icteroplombic colour, and when the strength and digestive functions have become quite re-established. Even then the patient should not expose himself to renewed poisoning, for one or two days' work often suffices to induce a relapse; so great is the predisposition which each intoxication leaves after it, perhaps in consequence of the economy still retaining a portion of the poison, and hence becoming more speedily saturated on renewed exposure.

M. Legroux concludes with observing that he has repeatedly had occasion to put these views into practice. He has tried every remedy proposed for the affection, and among other purgatives croton oil, which has obtained something like the reputation of a specific in this disease. It is, however, nowise superior to other purgatives, while it induces more irritation of the digestive canal. Of all means of treatment, he has found the well-known "La Charité" the best; for it is generally well borne, even when, as in obstinate relapsing cases, it has to be repeated two or three times. To this we have only to add effectual cleansing of the skin, and strengthening medicines, in order to fulfil every indication.—*Union Méd.*, 1867, Nos. 94, 95.

## PROVINCIAL CORRESPONDENCE.

### IRELAND.

DUBLIN, January, 1868.

THE important subject of the proper ventilation of public buildings was recently brought by Dr. John K. Barton before a meeting of the Royal Dublin Society, presided over by Dr. Churchill. Dr. Barton's paper gave rise to much discussion, and elicited the expression of a variety of opinions as to the best methods of accomplishing the object proposed in it. It is certainly much to be desired that public attention should

be directed to the quality of the "air we breathe," the purity of which is at least as important as that of the "water we drink," for it is a lamentable fact that the atmosphere of many of our crowded churches especially, is often so impure as to be injurious to health. For these reasons I consider that although his observations applied rather to Hospitals and Workhouses, Dr. Barton has done well in bringing the above-mentioned important question under the consideration of the mixed and highly influential meeting assembled on the occasion alluded to, in the Society's Board-room. In the course of his observations, Dr. Barton alluded to the recent proceedings at the London Lying-in Hospital, as strikingly illustrating both the importance of sufficient ventilation, and the determined opposition often made to its adoption, not only by servants, but by those who ought to be better informed.

At the same meeting Captain Maguire, R.N., presented to the museum of the Society a number of human skulls obtained by him in the Arctic regions while in command of the Plover, and mentioned that there never was any difficulty in removing such specimens, as the Esquimaux attach no importance to the preservation of the remains of their dead.

Mr. Moore, curator of the Society's beautiful Botanic Gardens at Glasnevin,—ground rendered classical by having been the constant resort of Swift, Addison, Tickell, and Delany,—exhibited a number of plants, whose unusual condition at this period of the year was indicative of the extreme mildness of the present season. Among the most striking of these were specimens of hawthorn in full blow, smelling as sweetly as that ornament to our Phoenix Park generally does in May, and potatoes from the open border forming tubers. Mr. Moore handed in a catalogue of the plants he had observed in a state of premature advancement, to serve as a permanent record in the Society's Journal of the unusual mildness of the winter of 1857-8. I may mention that the mean temperature of the month of December in Dublin was  $47^{\circ}180'$ ; the lowest point the thermometer fell to was  $33^{\circ}$ ; the highest it reached was  $57^{\circ}$ . The wind blew sixteen days from the south-west, nine days nearly due south, two days south-east, and four days west. The amount of rain which fell during the month was only 0.360 of an inch. With the exception of influenza, which has been prevalent, the season has not been unhealthy.

A meeting of the Irish Medical Association, open to the Profession, was held at the Royal College of Surgeons, on Wednesday, the 20th of January, for the purpose of taking into consideration the provisions of the Bill recently introduced into Parliament by the Right Honourable Henry Herbert, and the Attorney-General for Ireland, for the amendment of the Irish Poor-laws and of the Medical Charities Act of the 14th and 15th of her present Majesty; and also for the purpose of appointing a deputation to wait on the chief Secretary on the following day. The resolutions adopted were to the effect that the best interests of the poor, and especially of the sick poor, as well as of the rate-payers, would be best maintained by increasing, instead of diminishing, the influence of the Medical Profession in the administration of the Poor-law; and that the meeting, therefore, entirely disapproved of the clause providing for the substitution of non-medical persons for the present Medical inspectors. That the relieving officers should be empowered to cancel any Dispensary tickets issued to persons disentitled to gratuitous relief. That provision should be made to secure a continuance of salary to the Medical officer when actually incapacitated by illness, and that a substitute should be paid from the rates. That legal provision should be made for extraordinary services, which the dispensary and workhouse Medical officers are called on to render during the outbreak of alarming epidemics. That a minimum scale of salary should be adopted; and that inasmuch as the discharge of dispensary duties is necessarily attended with great expense,—say £50 per annum,—the minimum salary should be £100 a-year. That as great injustice is done to Medical officers by their being obliged to undergo a new election on the re-distribution of dispensary districts, a distinct provision should be made securing permanency of appointment. Lastly, it was resolved that the vaccination clause in the Medical Charities Act is unsatisfactory to the Profession and inefficient in practice, and that it requires amendment.

An adjourned meeting was held at the College on the following day, for the purpose of hearing the result of the interview with the Chief Secretary. Dr. Whistler stated that the

deputation had been courteously received by Mr. Herbert, who entered into all their representations, and evinced a great desire to do them justice in every possible shape. At the same time Dr. Whistler proposed that petitions to both Houses of Parliament, embodying the above resolutions, should be adopted; and his motion having been agreed to, the meeting broke up.

The Council of the Royal College of Surgeons in Ireland have announced that they will, on the first Monday in May, 1859, provided the essays sent in to them shall possess sufficient merit, proceed to award the first Carmichael prize of \$200 for the best essay, and the second Carmichael prize of \$100 for the next best essay, which may be sent to them, in accordance with the instructions of the late Mr. Carmichael, set forth in their announcement; on the state of the Medical Profession in its different departments of Physic, Surgery, and Pharmacy in the United Kingdom, at the time of writing the essays; the state of the Hospitals and Schools of Medicine, Surgery, and Pharmacy; and the state and mode of examination adopted by the several licensing Colleges or Corporations in each department; the writers to include in their essays suggestions for the improvement of the Profession in general, and to consider the best mode of rendering the examination as practical as possible.

## GENERAL CORRESPONDENCE.

### ACTION AND SOUNDS OF THE HEART.

[To the Editor of the Medical Times and Gazette.]

SIR,—In your No. of December 26, 1857, I see a notice of some experiments by Dr. Halford, intended to explain the action of the auriculo-ventricular valves of the heart and the mechanism of its first sounds. They seem to have been witnessed by a number of distinguished men, who do not however appear to be aware that Dr. Halford has been anticipated both in his theory and his method of illustrating it by Drs. Baumgarten and Hamerick some ten years ago. In 1847 a paper by the latter of these gentlemen appeared in the *Prager Viertel-jahreschrift* on this subject, and was transferred to the pages of the *Monthly Retrospect of the Medical Sciences*, at that time edited by Drs. A. Fleming and W. T. Gairdner, from which publication I will make a brief extract of the author's views, as the majority of your readers will probably be unable to put their hand upon either that or the original work. Dr. H. asserts that the auriculo-ventricular valves are closed by the counter-pressure of the ventricular blood suddenly developed by the contraction of the *auricles*, that the cavities of the auricles and ventricles during the heart's diastole are distended by the continuous current from the veins; whilst at this period the valves are to be found floating in the blood in the form of a funnel: that the object of the auricular systole is to induce such an amount of tension in the contents of the ventricles, and of course in the blood surrounding the funnel-shaped arrangement of the valves, as to cause their rapid closure; and that in this way only can regurgitation be prevented.

Dr. Halford states that his views can be illustrated in the following manner: If the heart be removed from the body and the auricles cut away, (it is better however to operate with one only,) the artery obstructed by ligature, or by filling it with wax, and the cavity of the ventricle filled with a saline solution, the valve is found lying in the position above described. If then a stream of water be directed upon the valve from the height of a foot, so as to imitate the sudden contraction of the auricle, the valve is seen to close with great rapidity. If however an attempt be made to imitate the ventricular systole, by squeezing the ventricle with the hand, a large portion of its contents regurgitates before closure is effected. Dr. Halford thinks that this closure is not due to the operation of the musclic papillares, but that it is much facilitated by the small specific gravity of the valves, which enables them to float upon the surface of the blood; though, as the editors of the *Retrospect* remark, the specific lightness of the valves cannot play an essential part in the phenomenon, as is indicated in the cases of prone animals, and of a man standing upon his head. Dr. Halford further states that the mechanism by which the valves of the arteries are closed is similar to that of the auriculo-ventricular valves. Immediately

upon the contraction of the ventricles, the pressure of the blood, attained in the large arterial trunks acting equally all directions, effects the closure of the semilunar valves. Their complete closure occurs contemporaneously with the end of the ventricular systole. When the ventricular diastole begins, the arterial retraction commences, and the wave of reflux from the large arteries falls upon the valves already closed, and thus is produced the clear second sound. There is no regurgitation, which would necessarily be the case, to a certain extent, if the valves were shut only by the returning wave of blood. Dr. Halford also thinks that the first sound is produced by the vibration of the tense auriculo-ventricular valves, acted on by the blood propelled against them during the systole of the ventricles, and by the vibration of the chordæ tendinæ.

As the small specific gravity of the valves is assumed to facilitate their closure, anything which can render them specifically heavier, as fibrinous deposits, in the case of debilitated individuals whose blood is of low specific gravity, may be conjectured to interfere with their action. It is in such cases that the reestablishment of an improved condition of the blood removes the murmur, as in typhus fever, severe pneumonia, etc. On similar principles the bruits observed in chlorotic patients may perhaps be explained.

The editors of the *Retrospect* state that they have witnessed these experiments of Dr. Hamerick, and testify to their accuracy. The paper, I may also add, contains several deductions from these observations, which, however, as they are not directly involved in the question at issue, it is unnecessary to quote. I trust, however, that I have cited enough to show that Dr. Halford's theory and experiments, whatever other merit they may have, at least have not that of novelty, though they may possess that of originality as far as he himself is concerned. At any rate, as the question of the mechanism of the first sound is an important one, he is entitled to credit for drawing attention to these views, and for attempting to invalidate the generally received, but probably incorrect explanation of the phenomenon.

I am, &c.

FRANCIS T. BOND, B.A. M.B. Lond.

Queen's College, Birmingham.

#### MR. SYME AND HIS COLLEAGUES.

[To the Editor of the Medical Times and Gazette.]

SIR,—As you have thought proper to publish a contradiction of my statement, that the letter of Dr. Christison, from which you quoted, was returned to him at his own desire, for the correction of an error which he had discovered it to contain, I beg to transmit a document that should remove any doubt upon this point.

In regard to the other representations of your correspondent, my silence will not occasion any surprise to those who are acquainted with the position of their author, or the subject to which they have reference.

I am, &c.

JAMES SYME.

2, Rutland-street, Edinburgh, Jan. 26.

"MY DEAR SYME,—When my letter was read, for the first time, before the Committee of the Town Council and our Medical Faculty, I mentioned some corrections which were necessary, asked leave to correct the letter accordingly, and at once obtained permission to do so.

"The original letter was therefore returned, with the corrections in a postscript.

"Whatever may have been the impressions of others about the letter having been withdrawn, I did not propose to withdraw it, I was not asked to do so, and I would not have consented to withdraw it, had this been asked.

"I am, yours always,

"Monday, Jan. 25, 1858."

"R. CHRISTISON."

#### THE "SQUATTING UTERUS."

[To the Editor of the Medical Times and Gazette.]

SIR,—I am in the habit of meeting occasionally a condition of the uterus which I have known for the last three years, and which, for want of a better term, I have named to myself the "squatting uterus;" but I trust that, after reading my

description, you will kindly assist me to some more appropriate denomination. It is where the body of the uterus is too flabby and atonic to support the fundus under the weight of the superincumbent viscera; it therefore bulges out in every direction, as the fundus sinks nearer to the os uteri, —producing a variety of symptoms, which I will now enumerate.

The patient complains of pain, which is occasionally sharp, at the symphysis pubis, increased by standing, exercise, constipation, or distended bladder; it is usually also aggravated by the passage of solid feces, and after emptying the bladder. The pulse is feeble, the bowels generally confined and unhealthy, and there are the ordinary dyspeptic symptoms which belong to this condition.

After a while the catamenia usually become more profuse, until each period assumes the form of passive menorrhagia. As her strength gives way, these various discomforts increase; she has constant pain in the region of the anus, as from piles; occasionally it is of a bearing down character, rendering defecation very painful.

On examination per vaginam, the uterus is found large, globular, and very tender; the cervix short, hard, and painful, or sometimes scarcely any cervix at all, the os uteri presenting a thick cushiony opening, which is acutely tender. The uterine sound passes the full length of two and a half, or sometimes three inches, and as soon as its progress is arrested by the fundus, or, in other words, as soon as the fundus is raised to its full extent, a remarkable change is perceived in the lower parts of the uterus; the hard and tender cervix becomes instantly soft and natural to the feel; it is much smaller, and is no longer tender to the touch. Before the uterus had been elongated by raising up its fundus with the sound it had the shape of a flattened orange, bulging out from the os, or shortened cervix, so as to occupy more room than ordinary in the direction of its horizontal diameter, as if its sides, not being able to support the weight of the fundus, had yielded, and assumed this bulging form. The swollen os, the hard tender cervix, sometimes so hard as almost to justify the suspicion of malignant disease; the enlarged, bulky, and tender uterus, its inferior segment overhanging and bulging beyond the cervix to an unusual extent, are the immediate effects of this atonic condition of the uterine walls, which, unable to support the weight of the fundus (and I may also add the weight upon the fundus), give way, and allow the fundus to sink down upon the os. The feeble returning circulation of the parts beneath (os and cervix) is thus obstructed; they become painful and swollen. The uterus, as I before observed, assumes the form of a flattened orange, and presses more or less on the bladder and rectum; hence we invariably find that the patient has a frequent want to empty the bladder, from the pressure of the uterus upon it not allowing more than a small quantity of urine to accumulate without producing uneasiness; and from the same cause she frequently complains of sharp pain behind the symphysis pubis after emptying the bladder, from its sides being pressed against each other. Constipation produces pain, not only by increasing the weight of the superincumbent intestines upon the fundus, and its consequent pressure upon the lower parts of the uterus, but the passage of solid feces is attended with some difficulty and much pain, not only along the course of the rectum, where it is compressed by the enlarged uterus, but also behind the symphysis pubis, from the rectum, when distended with feces, pushing the uterus bodily forward against the neck of the bladder.

The state of the patient's general health tends to excite rather than to allay the suspicion of malignant disease. The chylipoietic functions are much deranged; the face is sallow, its expression depressed; she is always in pain, unless in the horizontal position; the catamenia gradually become irregular, usually too frequent and too profuse, and not unfrequently of an unhealthy character. During the intervals there is a leucorrhœal discharge, which at times is watery or mucopurulent. She loses strength and flesh; and if an examination be made for the first time at this stage, the practitioner can scarcely avoid suspecting the commencement of uterine disease; at any rate, such is the engorgement of the whole organ, that, in spite of the feeble state of the patient, it would seem to justify active local depletion.

It is the uterine sound which will instantly and certainly disclose the real nature of the affection. It usually passes the os and cervix without pain; but, on pressing against the in-

ternal surface of the uterus, the great tenderness of the part shows that it is in a highly irritable condition. The uterine cavity is evidently larger than usual in the unimpregnated state; and when the sound has raised the uterus into its natural pyriform shape, it will frequently show a distance of three inches from the os to the fundus, even in a patient who has never been pregnant. If, while the sound is in the uterus to its full extent, we examine the os and cervix, and that part of the uterus which the finger can reach per vaginam, an immediate and striking change is perceived. The lips of the os have become thinner, the cervix soft and of the natural size, and we can now freely press them between the sound and the finger without producing pain. The inferior segment of the uterus, instead of bulging out immediately above the cervix, has reassumed its natural shape, and the patient generally acknowledges immediate relief to her various pelvic discomforts.

The treatment of this affection must obviously be of a general character. The patient's health and strength must be restored; and when these return, a healthy state of the uterus will return also. Local depletion is seldom necessary; the relief is but temporary, whereas the debility which it produces is apt to be of some duration. Soothing injections of decoctum papaveris, either by itself or with a little liquor plumbi diacetatis; or, if the parts be very irritable and tender, a suppository of plumbi diacet. and extr. conii form the only local treatment which I have seen necessary in the early part of the case. At a later period, as her health improves, a mild astringent injection to give tone to the parts will prove useful. The prone position has been beneficial in some cases, by taking off the weight of the superincumbent viscera from the uterus.

As the above observations have extended to some length I select the following case rather on account of its shortness, reserving some longer ones for a future occasion.

Mrs. W. B., aged 34, married 14 years. 1 child. Blondine.

Oct. 16.—Constant dull, and occasionally sharp, pain in pelvis. Leucorrhœa. Painful, irregular, and scanty menstruation, with clots. Bowels stated to be healthy. Tongue lobulated and fissured in a most singular manner.

Had a very severe labour twelve years and a-half ago, which appears to have been followed by sloughing and cicatrization of the lower part of the uterus; the closed os uteri was opened by an operation. At present is very weak; has night perspirations.

*Exam. per Vaginam.*—Os and cervix much swollen; very hard and tender; uterus is large and globular; uterine sound passes easily three inches; the internal surface of the uterus is extremely tender. On gently raising the fundus with the sound the lower part of the uterus assumes its natural pyriform shape; the os and cervix instantly become soft, and are no longer swollen and tender.

℞. Pil. hydrarg. chlorid. oo. gr. v. alternis noctibus.

℞. Acidi hydrochlor. dil., acidi nitrici dil. aa. ʒi., liq. taraxaci ʒi., inf. cinchonæ oblongifolia ʒviij. M.—Ft. mist., sumat cochl. magna ij. bis die ante cibum.

Oct. 19.—Had a sanguineous discharge for six or eight hours after using the sound, and passed a small clot. Yesterday she had a good deal of pain and then more discharge. Abdomen soft, but flatulent; a good deal of pain on right side of abdomen, below the umbilicus. The tongue looks like a piece of raw meat, seored and notched across at right angles. Bowels well moved, natural; urine clear; hæmorrhoidal fulness.

Hirudines iv. ori uteri. Suppositorio plumbi c. conio o. n. post hirudines.—Rep. mistura.

24th.—Much better. No discharge to-day; a slight amount yesterday. Tongue better; has been up for the first time and without pain; says she has the sensation that "the womb feels firmer." Bowels moved yesterday; no night perspirations.—Rep. mistura et suppositoria.

28th.—Abdomen large and tympanitic, but soft and flabby; has still a coloured discharge, and on emptying the bladder a little blood always passes. Bowels not open; the suppositories give relief. Rep. mist. et suppositoria.

℞. Extr. aloes aquosi ʒii., extr. hyoscyami ʒjss. mastiches gr. xij. M.—Ft. pil. xx. sumat j.—ij. h. s.

Nov. 11.—Much better and stronger; no pelvic pain; pills act well. Rep. omnia.

I have not enumerated all the pains and aches about the pelvis which this patient described, as they would rather

have tended to confuse than to elucidate the nature of the case. Suffice it to say that there was general internal discomfort from a large and painful uterus pressing on all the neighbouring parts. Any movement increased the pain, and compelled her to lie quite still. The enlarged state of the cervix with great hardness and tenderness, extending into the body of the uterus, and the irregular form of the os, which had been divided on each side, made me fear at first the presence of organic disease; and the history of her severe labour, from which she had never thoroughly recovered, rather tended to confirm these suspicions. The uterine sound slipped in with great ease, showing an enlarged uterine cavity, the inner surface of which was acutely tender. On gently pressing up the sound until its further progress was arrested, which was when it had passed three inches, a complete change took place; the uterus was no longer large, hard, and globular; the cervix had become taper and soft, and bore firm pressure of the finger without any pain. The acute tenderness of the uterine cavity evidently diminished, and the patient found herself relieved of that continued pain and discomfort which was evidently produced by the bulging uterus pressing upon the surrounding parts.

Although I could not obtain very satisfactory evidence about the state of the bowels, the remarkably fissured condition of the tongue, and its raw-looking surface were sufficient proofs that the liver and bowels were not in a healthy state. She was low and feeble; the leucorrhœa was as much the result of debility and want of tone, as the perspirations were.

I endeavoured to fulfil the above indications by the Plummer's pill every other night, and the mixture of nitro-muriatic acid in infusion of red bark, which is by far the best tonic in these relaxed flabby habits that I am acquainted with. As, however, the pain which continued was at any rate an evidence of considerable congestion, if not even of inflammatory action, I decided on applying four leeches to the os uteri, which gave great relief. She could move without pain; she lost her night perspirations and was gaining strength when she left town. I am, &c. EDWARD RIGBY.

Berkeley-square, January 23, 1858.

## TYPHUS AND TYPHOID FEVERS.

[To the Editor of the Medical Times and Gazette.]

SIR,—Since the question as to whom the merit of establishing the distinction between typhus and typhoid fevers is due has been lately mooted in your Journal, perhaps I may be permitted, through the same medium, to express, along with Mr. Cooper of Cromer, the opinion generally entertained in Scotland, and more particularly in the west of Scotland, where the facts are best known, with regard to the claims of my father, the late Dr. Perry of Glasgow. He himself in his short paper in the *Edin. Med. and Surg. Journal* for Jan. 1836, observes, "I do not pretend to say that all my observations are new. Many of them have been made by others before, but not one of them is stated on slight grounds, or on the faith of others, or is not the result of, or confirmed by, my own observations."

It is to be regretted that he did not again publish his observations in a more lengthened and detailed form, as he had such ample opportunities of making them on a very extensive scale, and had no lack of materials, but only the absence of a "desire to become an author." Far be it from me to say anything in disparagement of the admirable and important researches published by Dr. Jenner, or of the ability displayed in the paper by Dr. A. P. Stewart, but I would simply point out the priority of the opinions advanced by Dr. Perry. Other observers had previously given descriptions of typhoid fever, although not always styled by that name. Dr. Peëbles of Edinburgh had also published some researches upon fever, with a history of the eruptions in contagious fevers.

The aim of Dr. Perry in the paper above referred to, appears to have been not so much to give a detailed account of the difference in the symptoms between typhoid and typhus fevers, as to assign to the latter its true place among the exanthemata in the nosological table, whilst, at the same time, their non-identity was distinctly pointed out. As stated by Dr. Stewart (*Edin. Med. and Surg. Journal*, vol. xlv. p. 326), "Dr. Perry, of Glasgow, was the first whom I heard maintain the complete difference of the two eruptions, and I am now fully satisfied of the accuracy of that opinion."

With regard to the correctness of the proportion of typhus cases in which Dr. Perry found enlargement and ulceration of Peyer's glands, I will not at present enter into any discussion, but merely remark that other observers, and some who regard the mulberry rash as a *sine quâ non* of the disease, have also found enlargement and occasionally ulceration of those glands.

Although too much cannot be said in praise of the careful and lucid manner in which Dr. Jenner has traced out the distinctions between typhus and typhoid, I am inclined to think that too much credit has lately been given to him in London for the originality of his views, seeing that long before their publication the Medical Profession here had almost uniformly adopted the opinions advocated by Dr. Perry, and that hundreds of Medical men then in practice throughout the United Kingdom could have testified that the exanthematous nature of typhus, and the specific differences between it and typhoid, as well as other forms, had been distinctly brought to them by the late Dr. Perry in the wards of the Glasgow Royal Infirmary.

I am, &c.

ROBERT PERRY, M.D.

Glasgow, 8, Melrose-street, Jan. 20, 1858.

## MEDICAL NEWS.

**ROYAL COLLEGE OF SURGEONS.**—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted Members of the College at a meeting of the Court of Examiners on the 22d inst. :—

ADRIEN, JOHN, Oldtown, County of Dublin.

BEAUMONT, JOHN MORTON, Walton-place, Upper Chelsea.

BYRNE, THEODORE EDGAR DICKSON, Whickham, Gateshead-on-Tyne.

COOKE, LOUIS RICHARD, Orchard-street, Portman-square.

DALY, MICHAEL, Mallow, County of Cork.

FAULDER, JOHN JEFFERY, Newcastle.

FORD, JAMES, Sandford, Devon.

GIRAUD, CHARLES HERVE, Petersfield, Hants.

KING, GILBERT LENNOX, Royal Navy.

LEY, EDWIN GRANVILLE, Rochester, Kent.

ROBINSON, AUGUSTUS, Annapolis Royal, Nova Scotia.

At the same meeting of the Court, Mr. RICHARD EVANS passed his examination for Naval Surgeon; this gentleman had previously been admitted a member of the College, his diploma bearing date February 22, 1850.

**APOTHECARIES' HALL.**—Names of gentlemen who passed their examination in the Science and Practice of Medicine, and received Certificates to Practise, on Jan. 21 :—

BARRETT, JAMES, Banbury, Oxon.

DAVIES, HENRY HARRIES, Llandyssul, S. W.

## DEATHS.

**BENNETT.**—On the 25th inst., in Upper Baker-street, John Morris Bennett, M.R.C.S., Eng., 1811. Aged 69.

**DONNELLY.**—On the 19th inst., at Seabrook, Kent, William Donnelly, M.D. E., 1826. Aged 63.

**FOTHERGILL.**—On the 21st inst., John Fothergill, of Darlington, M.R.C.S., 1814.

**HASSARD.**—On the 16th December, on his passage to England, at the Danish Hospital, St. Thomas's, West Indies, of yellow fever, Ross Hassard, Surgeon Royal Artillery, third son of the late Major-General Hassard, Royal Engineers, aged 41.

**PRINGLE.**—On the 17th inst., at Notting-hill, Andrew Pringle, of Borgue. Aged 36.

**ROGERS.**—On the 21st instant, at Newport Pagnell, Bucks, John Rogers, Esq., in his 77th year.

## APPOINTMENT.

**BARON H. LARREY** has been appointed Medical Inspector of the Army, in place of the late M. Baudens.

**MR. T. APPELEY STEPHENSON**, M.R.C.S., Eng., L.S.A., was, on the 26th inst., elected Medical Officer to Nottingham Union District, No. 3.

**ROYAL MEDICAL AND CHIRURGICAL SOCIETY.**—The following gentlemen will be balloted for as Fellows of the Royal Medical and Chirurgical Society, on Tuesday evening,

February 9th, 1858. The ballot will be opened at half-past seven o'clock, and will close at half-past eight precisely :—William Warwick Harkness; Frederic George Reed; Joshua Harrison Stallard; John Richard Wardell.

**BRITISH METEOROLOGICAL SOCIETY.**—At the last meeting of the British Meteorological Society, held on Wednesday the 20th instant, Dr. R. D. Thomson, F.R.S. in the Chair; among other papers then read, and these almost exclusively meteorological in their character—was a communication eminently Medical in its bearing, from Dr. Smallwood, "On Ozone, and the Meteorology of Isle Jesus, Canada." In this paper Dr. Smallwood, without furnishing other results than those at which scientific observers have already arrived in reference to ozone, gives observations that tend to confirm those heretofore made in regard to the presence or absence of ozone in the atmosphere, as connected with the prevalence or non-prevalence of cholera.

**MR. GRIFFIN AND THE POOR-LAW GUARDIANS OF MELCOMBE REGIS.**—A new incident has just occurred in the way of an episode to the protracted struggle between Mr. Griffin and the Poor-law Powers. A vacancy having occurred for the appointment of Medical Officer to the Melcombe Regis district of the Weymouth Union, Mr. Griffin addressed a communication to the Guardians, offering himself as a candidate for the post. He asked for the appointment, not as a favour, but as a simple act of justice, in compensation for the hard work and small pay which he has so long experienced as Medical officer to his own district, in which the emoluments are much less than those of Melcombe Regis. He shows in his letter that the remuneration he has received as Medical officer has hitherto amounted to the astounding average of one shilling and threepence-halfpenny for each case!—some of the cases demanding serious surgical operations, such as amputation of the thigh, excision of the elbow-joint and the like. The remuneration in the Melcombe Regis district amounting to two shillings and twopence-halfpenny each case, Mr. Griffin, not unnaturally, seeks to improve his position by this addition, however scanty, to his present miserable pittance. The only answer given by the Guardians is the appointment of another person to the Melcombe Regis district; and Mr. Griffin again writes to his old friends at the Poor-law Board at Whitehall. In this document he points out not only the hardship of his own case, but the constant evasion and prevarication practised by the Board itself; and he quotes from former minutes and communications of the Board, to show how little is to be expected from its promises and professions. He is perpetually informed in these portentous documents that his case "shall receive due consideration," that it "will meet with due attention;" and after an infinite variety of phrases, filled with official verbosity and inanity, he finds that nothing whatever is done. We can imagine how the Board laughs in its sleeve when it receives one of Mr. Griffin's pungent communications, and orders the Honourable Mr. Slowcoach to give an official reply, characterized by the usual expanse of foolscap-paper and the usual poverty of ideas. But we hope that the House of Commons will bring these well-paid gentlemen to their senses, and prove to them, although perhaps too tardily, that the members of an honourable Profession are to be no longer insulted with impunity.

**EFFECTS OF NARCOTICS.**—Besides the various effects which are common to all the principal narcotics, each has characteristics of its own. Hashish produces real catalepsy, and exaggerates rather than perverts the reports of the senses as to external objects; the thorn apple, on the other hand, causes truly spectral allusions, and enables the Indian to converse with the spirits of his ancestors. The Siberian fungus gives insensibility to pain, without interfering with consciousness. The common puff-ball stops all muscular action, but leaves the perceptive powers untouched. (?) *Cocculus indicus* makes the body drunk, without affecting the mind. Cocoa has the wonderful power of sustaining muscular strength in the absence of food, and of preventing the wasting of the tissues of the body during the greatest and most prolonged exertion. The effects of the different narcotics are not only peculiar, but often opposed. Opium and hashish, common in many of their effects, are opposite in this, that the former diminishes sensibility to external impressions, whereas the latter almost infinitely increases it. Betel is even an antidote to opium, as tea is to alcohol. Tobacco suspends mental

activity; opium and hashish increase it a thousand-fold.—*National Review.*

**REORGANISATION OF THE POLISH MEDICAL SCHOOL.**—Last October an important change was made in the Medical organization of Poland. After the events of 1831 the Universities of Warsaw and Wilna had been closed, and the University of Cracow was the only poor resource that remained for the Polish youths wishing to pursue the Medical career. Even this was soon taken away by the annexation of the republic of Cracow to the empire of Austria. From that period the numbers who were enabled to study the Profession became very few, as the expenses were very great in going so far as the distant Russian Universities of Petersburg, Dorpat and Moscow. The result was that the new generation of Medical practitioners threatened to fall into mere mediocrity. The young Emperor Alexander II. during his recent visit resolved upon establishing a Medical faculty at Warsaw; and in a few weeks afterwards the new establishment was opened as the Imperial Academy of Medicine. The number of inscriptions for medicine and surgery almost immediately amounted to 200. At present the chairs for the first year's study, as chemistry, botany, natural history and anatomy, have been only filled; and the difficulty in finding professors capable of filling the higher chairs, especially the clinical and pathological chairs, is very serious. The means of overcoming it which has been suggested is to invite the return of some of the distinguished Polish Medical practitioners who emigrated after the events of 1831, and several of whom have since acquired great reputations abroad. It is hoped that Count Mouchanoff, Minister of Public Instruction, a man of remarkable ability, will recommend this step.

## VITAL STATISTICS OF LONDON.

Week ending Saturday, January 23, 1858.

## TO CORRESPONDENTS.

DR. CONOLLY's third paper will appear next week, with an Illustration as usual.

Mr. Paget's paper, "On some Affections of the Mouth and Fauces," shall appear next week.

Mr. Walker.—The address shall be sent.

Juvenis.—Physicians do not give receipts for their fees. The fee is honorary.

Dr. Sylvester's letter shall appear next week.

Juvenis begs to state that he submitted his plan (anonymously) a month ago for "A General Hospital Rate" to the Metropolitan Commissioners of the Board of Health, as well as to the Registrar-General for their consideration.

Inquirer.—An homoeopathic practitioner may accept an appointment under the Poor-law Guardians, and if he be legally qualified it might be difficult to displace him.

Dr. Goodwin's interesting case of Tetanus shall appear.

Juvenis recommends the following pomatum for the growth of the hair: Melt together four ounces each of beef marrow and oil of mace, and having strained through a fine sieve stir in (previously dissolved in half an ounce of tincture of tolu), two drachms of balsam of tolu, and one drachm each of oil of cloves, and the same of camphor. A piece, the size of a pea only, to be well rubbed in night and morning.

COMMUNICATIONS have been received from—  
Dr. CONOLLY; Dr. RIGBY; Mr. SYME, Edinburgh; Mr. PAGET; Mr. WHARTON JONES; Dr. BUCHANAN, Glasgow; Dr. G. JOHNSON; Dr. MARCET; Dr. CAMPS; Mr. HUSSEY, Oxford; Dr. SYLVESTER; Dr. GRAILY HEWITT; Dr. GOODWIN, Norwich; Mr. HUGHES; Mr. DAVIS; Dr. COLLIVER; Mr. GRIFFIN; Mr. A. WALKER; Mr. BARLOW; Mr. RIVERS; SECRETARY GENERAL BOARD OF HEALTH; Mr. WATTS; Mr. McDERMOTT; Mr. W. PARKER; Mr. BARLOW; Mr. PALMER; Mr. STEPHENSON; Dr. BAINES; Mr. E. S. BENNETT; Mr. J. ERTWILER; Dr. OXLEY; Mr. J. BROADBENT; Mr. J. CARMICHAEL; Mr. E. BATT; Dr. W. TAYLOR; Mr. H. E. WATTS; Dr. F. W. BLAKE; Mr. H. VASEY; Mr. C. SPENCER; Mr. J. LOVEGROVE; Mr. J. BIRNS; Dr. MORIARTY.

## APPOINTMENTS FOR THE WEEK.

Jan. 30, Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's 2 p.m. Charing Cross, 1 p.m.

MEDICAL SOCIETY OF LONDON, 8 p.m.: Mr. Henry Smith, "On some points connected with the treatment of obstinate Stricture of the Urethra."  
ROYAL INSTITUTION, 3 p.m.: Mr. Bloxam, "On the Chemistry of the Elements."

### 1. Monday.

Operations at the Royal Free Hospital, 1 p.m.; Metropolitan Free Hospital, 2 p.m.; Orthopedic Hospital, 3 p.m.

ENTOMOLOGICAL SOCIETY, 8 p.m.

ROYAL INSTITUTION, 2 p.m. (General Monthly Meeting.)

EPIDEMIOLOGICAL SOCIETY, 8 p.m.: Dr. Snow, "On Drainage and Water Supply, in connexion with Public Health."

### 2. Tuesday.

Operations at Guy's, 1 p.m. Westminster, 2 p.m.

PATHOLOGICAL SOCIETY, 8 p.m.

ROYAL INSTITUTION, 3 p.m.: Professor Huxley, "On Animal Life."

### 3. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m.;

Orthopedic Hospital, 3 p.m.

GEOLOGICAL SOCIETY, 8 p.m.

PHARMACEUTICAL SOCIETY, 8 p.m.

### 4. Thursday.

Operations at St. George's, 1 p.m.; Middlesex, 1½ p.m.; Central London Ophthalmic, 1 p.m.; London, 1½ p.m.

ROYAL SOCIETY, 8½ p.m.

ZOOLOGICAL SOCIETY, 8 p.m.

LINNÆAN SOCIETY, 8 p.m.

CHEMICAL SOCIETY, 8 p.m.

MIDDLESEX HOSPITAL MEDICAL SOCIETY, 8 p.m. Mr. Digby, "On the Causes and Treatment of Inefficient Action of Uterus in Parturition."

ROYAL INSTITUTION, 8½ p.m.: Professor Tyndall, "On Heat."

GROSVENOR PLACE SCHOOL MEDICAL SOCIETY, 7½ p.m.

HARVEIAN SOCIETY: Haynes Walton, Esq., "Observations on some forms of Impaired Vision, including Diagnosis and Treatment." N.B. The Ophthalmoscope will be exhibited, and its use explained.

### 5. Friday.

Operations at the Moorfields Ophthalmic, 10 a.m.; Westminster Ophthalmic, 1½ p.m.; Great Northern, 2½ p.m.

ROYAL INSTITUTION, 8½ p.m.: Dr. Lankaster, "On the Drinking Waters of the Metropolis."

WESTERN MEDICAL AND SURGICAL SOCIETY, 8 p.m.: Dr. Ogle, "On the Registration of Sickness." Mr. Hatfield, "On the post-mortem examination of a Case of Sudden Death, and the discovery of O.I. in the right pleural cavity. (Council Meeting at 7.)

## The New Sydenham Society.—At the

Inaugural Meeting of this Society, held January 18th, at the Rooms of the Medical Society of London, Dr. C. J. B. Williams in the Chair, the following Resolutions were adopted:—

I.—Proposed by Dr. Watson, seconded by Mr. Solly, and carried unanimously—"That a Society be instituted for the purpose of supplying certain deficiencies in the existing means for diffusing Medical Literature, and that such Society be called 'The New Sydenham Society.'"

II.—Proposed by Dr. Gull, seconded by Dr. Hodgkin, and carried unanimously—"That the chief objects of this Society shall be the republication or translation of valuable British or Foreign Medical Works, Papers, and Essays, difficult of access to the Members of the British Profession."

III.—Proposed by Dr. Peacock, seconded by Mr. Erichsen, and carried unanimously—"That the Laws now read be adopted as the Laws of the New Sydenham Society."

IV.—Proposed by Dr. Budd, seconded by Dr. Sieveking, and carried unanimously—"That the President, Vice-Presidents, Council, etc. as proposed by the Provisional Committee, be elected as the Officers of the Society for the ensuing year."

### OFFICERS FOR 1858.

PRESIDENT.—C. J. B. Williams, M.D. F.R.S. etc.  
VICE-PRESIDENTS.

Sir Henry Holland, Bart. F.R.S.  
Sir Philip Crampton, Bart. F.R.S.  
Thomas Addison, M.D.  
E. W. Acland, M.D. F.R.S. D.C.L.  
Oxford.  
William P. Alison, M.D. F.R.S.E.  
B. G. Babington, M.D. F.R.S.  
Thomas Mayo, M.D. F.R.S.  
J. Y. Simpson, M.D., Edinburgh.

J. A. Symonds, M.D. F.R.S.E.  
Bristol.  
Thomas Watson, M.D.  
W. Sands Cox, Esq., F.R.S.  
J. H. James, Esq., Exeter.  
Cresser H. Hawkins, Esq., F.R.S.  
James Paget, Esq., F.R.S.  
Samuel Solly, Esq., F.R.S.  
T. P. Teale, Esq., F.L.S., Leeds.

### COUNCIL.

Robert Barnes, M.D.  
William Brinton, M.D.  
John S. Bristowe, M.D.  
Andrew Clark, M.D.  
C. De Morgan, Esq.  
James Dixon, Esq.  
W. T. Gairdner, M.D., Edinburgh.  
C. Radcliffe Hall, M.D., Torquay.  
George Harley, M.D.  
Thomas Inman, M.D., Liverpool.  
George Johnson, M.D.  
Charles Murchison, M.D.  
John W. Ogle, M.D.  
Thomas B. Peacock, M.D.

Richard Quain, M.D.  
W. Sedgwick Saunders, M.D.  
William H. Stone, M.D.  
Thomas H. Tauner, M.D.  
John E. Erichsen, Esq.  
John Hilton, Esq., F.R.S.  
George M. Humphrey, Esq., Cambridge.  
William B. Page, Esq., Carlisle.  
H. Spencer Smith, Esq.  
John S. Soden, Esq., Bath.  
Henry Thompson, Esq.  
T. Jolliffe Tufnell, Esq., Dublin.  
T. Spencer Wells, Esq.

TREASURER.—G. Hillaro Barlow, M.D., 5, Union street, S.E.

SECRETARY.—Jonathan Hutchinson, Esq., 14, Finsbury Circus, E.C.

N.B.—Six Vacancies yet remain for Provincial Members of the Council: these will be filled up when the canvass for Members shall be more advanced.

At a Meeting of the Council, held at Dr. Williams's, on January 25, the following was adopted as the

### PROSPECTUS

of the new Society:—

The objects to which the New Sydenham Society will direct its attention are the following:—

I. The translating and editing of valuable Foreign Works on Medical Science, as also of important Papers which may have recently appeared in Foreign Journals, Transactions of Societies, etc. These works, papers, etc. will be translated in full, and brought out as early as possible after their original publication.

II. The reproduction of British Works, Lectures, and Papers, which, while of great practical value, are out of print or difficult to obtain, excluding the works of living authors.

III. A Year-Book of Reports in abstract of the progress of the different branches of Medical Science, compiled by a Committee.

IV. Should the funds prove adequate, it is proposed also to prepare Volumes of Medical Bibliography and Medical Biography.

It will be observed that the New Sydenham Society aims chiefly at the republication of Modern Works and Papers, especially those of a directly practical class. In order to secure a representation of the wishes and opinions of the general body of Members of the Society, it is proposed that its Council shall always include a certain number of provincial residents, and that its Annual General Meeting, at which the election of Officers and Council will take place, shall be held at the same time and place as the Anniversary Meeting of the British Medical Association.

After careful inquiry into the causes which led to the decline of the late Sydenham Society, it is believed that two of the most important were the expense of its management, and the inefficient means employed for enlisting new members, collecting subscriptions, and issuing books. It is, therefore, proposed, in order to remedy these defects, that the New Sydenham Society shall adopt a system of rigid economy in its management; and it is further contemplated to enlist a much larger number of Local Secretaries, and to adopt other precautions for ensuring punctuality in all its departments.

The assurances of support already received are so numerous, that it is intended that the Society shall commence its operations at once. The Council, however, earnestly beg of all interested in its prosperity to remember, that great success can only be attained by a Society of this kind when the number of members is very large. The expense of printing 5000 copies of a book is but little more than that of printing 500. It is merely the difference of paper, binding, and a trifle for presswork. It thus becomes the direct interest of every member to enlist as many additional members as possible, since by so doing he will not only extend the influence of sound Medical Literature, but will increase the number of works to be obtained for his own subscription.

The Subscription will be One Guinea annually, payable in advance.

NOTE.—It is intended as early as possible to appoint Local Secretaries in all towns of sufficient size, and by their aid to make a general canvass of the Profession. It will, however, very greatly assist the Council, if those gentlemen who have already determined on joining the Society will forward their names to the Secretary without loss of time.

## Carriages, New and Second-hand, of

superior style, sterling quality, and finest finish at reasonable rates, for cash, credit, job, or exchange. Circular of prices on application. Credit given when required. Buyers should take carriages on trial, with power to purchase by yearly payments, and thus prove them.

OFFORD'S PATENT MEDICAL-MAN'S BROUGHAM MANUFACTORY, 79, WELLS-STREET, OXFORD-STREET.

TO SURGRONS, APOTHEJARIES, AND DRUGGISTS.

## Important Saving, by Prepayment

in the PURCHASE of  
NEW WHITE ROUND MOULDED VIALS OF THE BEST QUALITY.

PELLATT and Co. submit the following PRICES of VIALS, for PREPAYMENT only:—

1 oz., 1 oz., 10 dr., and 14 oz. per Gross, 6s.	In quantities of not less than
14 dr., and 2 oz.	7s.
3 oz.	8s.
4 oz.	10s.
6 oz.	15s.
8 oz.	18s.
4½ oz. graduated in 3 doses.	15s. 6d. chaser.

The above Prices being based upon a calculation which excludes all charges whatever between the Manufacturer and the Consumer, no attention can be paid to any order not accompanied by a remittance in full, made payable in London.—P. and Co. do not supply Green Glass.—Orders and remittances to be addressed,

PELLATT & Co.,  
FALCON GLASS WORKS, LONDON.

## The Medicated Cod Liver Oils,

comprising

OLEUM MORRHUE CUM QUINA.  
OLEUM MORRHUE CUM FERRI IODIDO.  
&c. &c. &c.

Prepared only by SAVORY and MOORE, 143, New Bond-street.

## Liquor Pepsinæ.—A Convenient and

efficacious preparation by  
SAVORY and MOORE, 143, New Bond-street.

## Glycerine.—An Impure Glycerine is

now being sold on the statement that it is as pure as the Patent Dissipated Glycerine of Price's Patent Candle Company. The Company beg the application of the following simple tests:—For unpleasant smell, rub a few drops over the back of your hand, when the fetid mouse smell will, if present, at once come out. For lead and other metallic impurities, test by a current of sulphuretted hydrogen. For lime and other earthy impurities, test by oxalate of ammonia or chloride of barium. The Company are not responsible for any Glycerine except that sold in bottles having capsules lettered "Price's Patent." Price's Patent Candle Company, Limited, Belmont, Vauxhall, London.

## Pepsine.—M. Boudault begs to state

that he cannot be answerable for the purity and strength of any Preparation sold under his name unless obtained from his sole Agent, Mr. PETER SQUIRE, her Majesty's Chemist, 277, Oxford-street, London, to whom all applications respecting it must be addressed.

Second Edition of Boudault on "Pepsine," with Remarks by English Physicians Edited by W. S. SQUIRE, Ph.D., published by J. Churchill, London, may be also had of the Author, 277, Oxford-street, price Sixpence.

## For Use Medicinally, in all Diseases of

the STOMACH, CHEST, etc., for dressing and deodorizing cancer and all foul wounds, for purifying sick chambers, for embalmment of the dead, etc. Mr. JASPER ROGERS'S PATENT CARBONIZED PEAT MOSS. The various kinds of powder and lozenges are prepared solely by the Health of Towns Improvement Company. Sole Wholesale Agent, Joseph G. Thompson, Esq., 2, Adelaide-place, London-bridge, London, E.C., and 5, Donegal-square, Belfast; sold by Mr. W. L. Bird, Pharmaceutical Chemist, 42, Castle-street, East, Oxford-street, W.; Mr. J. Johnson, Chemist, 123, Upper-street, Islington, N., London; Messrs. Brewley and Evans, Dublin; and all respectable Chemists. See extracts from publications on the subject, with the preparations.

PURE SPIRITS FOR THE FACULTY.

## S. V. R. 56 o.p., 17s. 6d. net Cash.

This quotation admits of neither credit nor discount, and is per gallon must be added for packages, to be allowed on their return.

HENRY BRETT and CO., Old Fugival's Distillery, Holborn.

BROUGHAMS.

## Kinder, M'Naught, and Smith,

MANUFACTURERS, WORCESTER, beg respectfully to invite the attention of professional men to their improved Medical Broughams, as under:—

Width of Seat.	Weight.	Price.
3 ft. 5 in.	7½ cwt.	85 Guineas.
3 ft. 6 in.	8½ cwt.	95 Guineas.
3 ft. 7 in.	9 cwt.	100 Guineas.

The latter, including a segmental front, with seat for third person.

These Carriages are constructed, by the aid of machinery, of the best material, are of excellent workmanship, and particularly adapted to the wants of medical men, either in town or country. Drawings and other particulars forwarded on application.

# ROYAL MEDICAL BENEVOLENT COLLEGE,

(INCORPORATED BY ACT OF PARLIAMENT.)

*Patron.*—HER MOST GRACIOUS MAJESTY THE QUEEN.

*President.*—THE RIGHT HONOURABLE THE EARL MANVERS.

*Visitor.*—THE LORD BISHOP OF WINCHESTER.

*Treasurer.*—JOHN PROPERT, Esq.

The Council of the Royal Medical Benevolent College have the pleasure to inform the Governors and Friends of the Institution that the SIXTH ANNUAL FESTIVAL will take place at the FREEMASONS' TAVERN on WEDNESDAY, the 24th of March next, when the Right Honourable the LORD STANLEY, M.P., has kindly consented to take the Chair. Gentlemen who are willing to act as Stewards on the occasion are requested to send their names to the Treasurer, or to the Secretary, at the office of the College in Soho-square. The liability of each Steward is limited to the cost of a dinner ticket.

The following Noblemen and Gentlemen have already undertaken to officiate as Stewards. A further List will be published shortly.

The Right Honourable the Earl of Huntingdon.  
Sir John Forbes, M.D. D.C.L. F.R.S., Old Burlington-street.  
The Rev. John Jennings, M.A., Canon of Westminster.  
The Rev. P. Melancthon Holden, St. Paul's Chapel, Gt. Portland-st.  
Richard Bagge, Esq., Gaywood Hall, Lynn.  
Henry Blenkarne, Esq., Dowgate Hill.  
Nathaniel Clifton Esq., Cross-street, Islington.  
Edward Clifton, Esq., Russell-place, Fitzroy-square.  
Thomas R. Colledge, M.D., Cheltenham.  
Charles Cotton, M.D., Lynn.  
Henry Curling, Esq., Ramsgate.  
George Thomas Dale, Esq., Pembroke-place.  
William Dalton, Esq., (Hon. Local Sec.,) Cheltenham.  
Horatio G. Day, Esq., (Hon. Local Sec.,) Isleworth.  
Charles Drage, M.D., (Hon. Local Sec.,) Hatfield.  
Robert Dunn, Esq., Norfolk-street.

Richard D. Edgecombe, Esq., Shaftesbury-crescent.  
George Fincham, Esq., Marlborough Hill.  
Frederick Goodchild, M.D., Princess's-terrace.  
Henry Hancock, Esq., Harley-street.  
Richard Hassall, M.D., Richmond.  
John Vincent Hawkins, M.D., Lynn.  
W. C. Hoffmister, M.D., (Hon. Local Sec.,) Cowes.  
George C. Jonson, Esq., Eaton-place South.  
T. Marsters Kendall, Esq., (Hon. Local Sec.,) Lynn.  
Charles F. J. Lord, Esq., Hampstead.  
George Pinckard, Esq., St. James's-square.  
John Probert, Esq., New Cavendish-street.  
J. O. Smetham, Esq., Mayor of Lynn.  
William E. Snow, Esq., Tredegar square.  
Henry Sterry, Esq., Paragon, New Kent-road.  
Francis Webb, Esq., Chancery-lane.

By order of the Council,

37, Soho-square, London, January 26, 1858.

ROBERT FREEMAN, Secretary.

HERBERT WILLIAMS, Assistant Secretary.

[ESTABLISHED 1841.]

## Medical, Invalid, and General Life

OFFICE, 25, PALL MALL, LONDON.  
Empowered by Special Act of Parliament.

By the Annual Report of 1857, it appeared that the number of Policies then in force was 3434, insuring £1,837,500, and yielding an income of £55,207.

At the SIXTEENTH ANNUAL MEETING, held on 26th November, 1857, it was shown that on the 30th June last:—

The Number of Policies in force was .. .. .	6255
The amount Insured was .. .. .	£2,917,598 13s. 10d.
The Annual Income was .. .. .	£125,113 3s. 8d.

Two Bonuses have been declared (in 1848 and 1853), adding nearly Two per cent. per annum on the average to sums assured, and by which a Policy of £1000 issued in 1842 on a healthy life, is now increased to £1360.

Profits divided every five years—next division in 1858.

The Society, since its establishment, has paid claims on 776 Policies, assuring £319,884.

Assurances are effected at home or abroad on healthy lives at as moderate rates as the most recent data will allow.

Indian Assurances at very moderate rates, and great facilities given to assurers.

Invalid lives assured on scientifically constructed tables.

Policies issued free of stamp duty, and every charge but the Premiums. Medical men are paid a guinea for each report, and receive the same advantages as Solicitors for any business they may introduce.

Active working agents wanted for vacant places.

Prospectuses, Forms of Proposals, and every other information, may be obtained of the Secretary at the Chief Office, or on application to any of the Society's Agents in the country.

C. DOUGLAS SINGER, Secretary.

## Norwich Union Life Assurance Society.

Instituted 1808. Invested capital exceeding £2,000,000 sterling.

This Society is one of the very few purely Mutual Insurance offices, the whole of the profits being divided among the policy-holders.

The rates are considerably below those usually charged. Thus at the age of 40 the sum of £32 19s. 2d., which at the ordinary premium will insure £1000—with the Norwich Union will insure £1095 4s., giving an immediate bonus in addition to subsequent accumulations.

Annuities and special risks undertaken on favourable terms.

For forms of proposal and prospectuses apply to the Society's offices, 5, Crescent, New Bridge-street, Blackfriars, E.C., and Surrey-street, Norwich.

### SPECIAL NOTICE.

To secure the advantage of this year's entry, Proposals must be lodged at the Head Office, or at any of the Society's Agencies, on or before 1st March.

### MUTUAL LIFE ASSURANCE.

THE WHOLE PROFITS DIVIDED AMONGST THE ASSURED.

## The Scottish Equitable Life Assurance

Society.

INSTITUTED 1831.

Incorporated by special Act of Parliament.

The Fund accumulated from the Contributions of Members exceeds ONE MILLION STERLING.

The Annual Revenue exceeds ONE HUNDRED and SEVENTY-SIX THOUSAND POUNDS.

The amount of existing Assurances exceeds FOUR MILLIONS AND THREE QUARTERS.

The amount paid to the Representatives of Deceased Members is upwards of Nine Hundred Thousand Pounds, of which One Hundred and Twenty Thousand Pounds consisted of Bonus Additions.

A Division of Profits is made every Three Years, the next Division being at 1st March, 1859.

### HEAD OFFICE.

26, St. Andrew-square, Edinburgh.

ROBERT CHRISTIE, Manager.

WILLIAM FINLAY, Secretary.

LONDON OFFICE—26, POULTRY, E.C.

ARCHD. T. RITCHIE, Agent.

### WESTERN LONDON OFFICE.

6a, James's-street, Westbourne-terrace, W.

CHARLES B. LEVER, Solicitor, Agent.

## Wines from South Africa.—Port,

SHERRY, etc., TWENTY SHILLINGS PER DOZEN. These Wines, the produce of a British colony, which has escaped the vine disease (the vintage occurring in February may account for the same), are in consequence wholesome, and are warranted free from acidity and brandy, are admitted by Her Majesty's Customs at half-duty, hence the low prices. A Pint Sample Bottle of each for twenty-four stamps, Bottles included. Packages allowed for when returned.

"We have taken the trouble to try Mr. Denman's wines, and have also submitted them to several of the clergy, and the opinion formed is that they are worthy of being patronized."—Clerical Journal, October 22, 1857.

EXCELSIOR BRANDY, Pale or Brown, 15s. per gallon, or 30s. per dozen. Terms—Cash. Country orders must contain a remittance. Cheques to be crossed "Bank of London."

J. L. Denman, Wine and Spirit Importer, 65, Fenchurch-street. Counting-house entrance, first door on the left up Railway-place.

## ORIGINAL LECTURES.

## CLINICAL LECTURE

ON

HEMIPLEGIA DEPENDENT ON ATROPHIC  
CEREBRAL SOFTENING.

DELIVERED AT

King's College Hospital,

By R. B. TODD, M.D. F.R.S.

Physician to the Hospital, &amp;c.

(Reported by Dr. CONWAY EVANS.)

GENTLEMEN,—The best instance of disease which I can today bring under your notice is that of a woman named Mary Anne Godfrey, who is now lying in Ward No. 7, with hemiplegia of the right side. She tells us she is 34 years of age, and that this is the second time she has been in the Hospital, for she was here under my care with hemiplegia of the left side about five years ago. Upon looking over my case-books I find that this statement of hers is quite correct, and I have here the notes which were taken of her case when she first came under my observation.

The special interest of the case consists in the fact of her having been twice the subject of very complete hemiplegic paralysis; and having completely recovered from the first attack, she now, after the lapse of so long a period as five years, suffers a second attack on the opposite side.

The date of her former admission was May 21, 1860, and she was then 29 years of age. It appears that her health generally had been good until December, 1849, when she had an attack of rheumatic fever, for which she was under treatment in a metropolitan hospital. Ever since that time she has been more or less subject to rheumatic pains. It is not at all improbable that during this first attack of rheumatism there may have been some endocardial affection, for we found then and still find upon examination that a bellows-sound, accompanying the systole, is audible over the base of the heart and the region of the aorta.

In January, 1860, a month after the rheumatic fever, she had a fit apparently epileptic, and came out of it in two hours with the full use of her limbs. In March of the same year she had a second similar seizure, which lasted two hours, and on coming out of it she found her left arm paralysed and her face awry, but these effects disappeared in half an hour. Three weeks subsequently she had a third attack, also followed by transient paralysis of the left side. From this time she continued well, until the morning of May 17th, when she awoke, after a heavy sleep, with complete hemiplegia of the left side. In this state she was brought to the Hospital four days after the attack. Here she was at once placed under a supporting plan of treatment, the administration of quinine and iron, and an occasional purgative, together with a nutritious diet; in six weeks she perfectly recovered the use of her limbs, and left the Hospital quite well.

The history of the attack for which she has now been admitted into the Hospital is this:—On the evening of November 6th, 1866, while walking in the street, she suddenly fell down in a state of insensibility; she was taken up and carried home, and it was then discovered that she was paralysed on the right side of her body. She remained insensible all night, and the following morning was cupped on the back of the neck. And here let me remark that I hope to see the day when this practice of abstracting blood as a matter of routine (for it is really nothing more than this) in cases of sudden paralysis will be abandoned; undoubtedly it is daily becoming less frequent. Many men, when summoned to a case of sudden palsy, whether with or without loss of consciousness, either cannot or will not take the trouble to investigate the case thoroughly, and the only conclusion at which they seem able to arrive, is that the symptoms in some way or other depend upon congestion of the brain, that there is too much blood in the head; and, therefore, that bleeding must be resorted to, whether from the arm, or by applying leeches to the head, or cupping on the back of the neck.

VOL. XXXVII. No. 968. NEW SERIES, No. 397.

But to return to our case. In the course of the evening the patient recovered her consciousness, and this fact, in the opinion of many, would be a sufficient justification for the bleeding. But although she recovered her consciousness, the paralysis continued, and her power of articulation was considerably impaired, while vision and hearing were also somewhat affected. For the following two or three days she was rather feverish, but neither subsequently to nor during the attack were her limbs at all drawn up, nor was she in the least degree convulsed. The catamenia were quite regular; and there was nothing in her history to justify a suspicion of a syphilitic taint.

On the admission of this patient there was complete paralysis, as regards voluntary motion, of the muscles of the right side of the body; indeed, it is rare to meet with a case of hemiplegia more complete than this had been, for no reflex actions could be induced by tickling the sole of the foot, except occasionally, when we succeeded in exciting a slight action in one or two muscles connected with the great toe. The muscles of the paralysed limbs were all perfectly flaccid and relaxed; the mouth was slightly drawn to the left side; the tongue, when protruded, diverged somewhat towards the right side; the patient could see and hear well; the pupils were equal; there was no headache, but, as I before mentioned, a systolic bellows-sound was audible over the base of the heart.

Let me impress upon you the importance of observing and noting in your record in all cases of hemiplegia the condition of the muscles of the paralysed limbs. You should always flex the forearm upon the arm, and the leg upon the thigh, and carefully ascertain whether any of the muscles of these parts offer any resistance to these movements, and if they do, you should note the degree of this resistance—whether it be merely a slight resistance, or whether it amount to a state of greater or less rigidity. Sometimes you will find that the biceps is the only muscle which at all opposes your movements, and in other cases it is the triceps alone which resists; while in other cases you will find all the muscles of the limb in a state of intense rigidity. You will readily understand the great importance of attending to these points when I tell you that these different states of the paralysed muscles—flaccidity, slight resistance, or absolute rigidity—are indications of different states of brain. Thus the perfectly flaccid condition of the muscles of the palsied limbs is indicative of a cerebral lesion distinctly atrophic in its nature—a lesion the very opposite of inflammatory, of a low kind, and one in which there is a tendency to waste, and in which the vital powers are *below par*.

The resistive state of the paralysed muscles shows that the cerebral lesion, whatever it be, is of an *irritative* kind. A very frequent cause of this state of muscles is a small apoplectic clot with laceration by the effused blood of some of the healthy brain-substance immediately adjoining it. When the palsied muscles are hard and rigid, and almost in a tetanic condition, the brain lesion is of a more distinctly and decidedly irritative kind than in the last-mentioned class of cases, in which there is merely simple resistance, and is sometimes of an inflammatory nature. These are the cases best adapted for bleeding, or, at all events, for mercury. But when there is merely resistance of the paralysed muscles, and, *a fortiori*, when they are perfectly flaccid, these remedies are inadmissible and generally calculated to do harm.

Here, then, we have in the case before us all the indications of paralysis dependent on an atrophic lesion of the brain—all the characters, in fact, of an ordinary case of a common form of hemiplegia, but a form which is more frequently met with in persons more advanced in life than our patient. I omitted to mention that sensibility was considerably diminished in the paralysed limbs after the attack, and (what is not very common) it has since exhibited no decided tendency towards a speedy return. If you converse with this patient you will perceive that, although she is in a low and depressed state, which is partly perhaps due to the shock of the attack, and partly also to an enfeebled and impaired health prior to the seizure, her intellectual powers are pretty perfect; and I therefore infer that her hemispherical convolutions are not damaged.

The lesion in this patient is *atrophic* or *white softening*, and its seat is, I believe, some part of the *centre of volition*—that part of the brain which is immediately concerned

in voluntary actions, i.e. the corpus striatum and optic thalamus on the left side, or parts in immediate connexion with these ganglia. According to the view which I take of the physiology of the brain, I am led to regard these two great nervous masses—the corpus striatum and optic thalamus—as connected with the centres of volition and sensation respectively, much in the manner in which the capital of a pillar is connected with its column; and hence it is that lesion of the former gives rise for the most part to paralysis of voluntary motion, while sensation is chiefly impaired when the latter is the part most involved in disease. Still, however, it should always be borne in mind that lesion of either of these cerebral ganglia produces symptoms very similar to those caused by disease of the other. That the paralysis of motion, which is thus induced, should be on the opposite side of the body, may appear inconsistent with the view which I take of the different functions of these ganglia as separate centres, but this inconsistency is only apparent, and is entirely removed, I think, when we bear in mind, the exceedingly intimate connexion which exists between these two great masses of nervous matter, and when we remember how they lie imbedded the one in the other; so much so that it is very difficult to imagine lesion of the one without some affection of the functions of the other. But inasmuch as the optic thalamus is by far the larger of the two centres, and inasmuch, also, as it has much more extensive connexions with surrounding parts than the corpus striatum, so its function—common sensation—escapes far more frequently than the function of the corpus striatum—voluntary motion; and it is much more common to meet with cases in which the function of the corpus striatum is influenced by lesion of the optic thalamus, than those in which the function of the optic thalamus is interfered with, in consequence of a diseased condition of the corpus striatum. The explanation of this fact is, as it appears to me, to be found in the immense connexions of the thalamus with the corpora quadrigemina, pons variolii, etc.,—in a word, with the mesocephale. In consequence of the great size and extensive connexions of the optic thalamus, it requires a very large lesion of this body to affect sensibility materially; hence, then, whenever I find in a case of hemiplegia that sensation is much and permanently impaired, I am disposed to think, *ceteris paribus*, that the brain-lesion is considerable, and that it involves a pretty large portion of the optic thalamus with perhaps, also, some part of the corpus striatum.

But in the majority of cases of hemiplegia the paralysis is of motion only, although in most there is more or less numbness of the palsied limbs immediately after the attack. This latter symptom generally passes off in the course of a few days, or even hours, and the sensibility becomes perfectly restored, while voluntary motion remains more or less completely paralysed; and in such the lesion is chiefly of the corpus striatum, or of parts in its immediate vicinity, the optic thalamus either entirely, or almost entirely escaping. From the completeness of the paralysis of voluntary motion, and even of reflex actions in our patient upstairs, together with the great degree of impairment of sensibility, I am inclined to think that the lesion in this case is very extensive, and that it is, as I before said, of an atrophic character—white softening.

Now white softening depends for the most part upon any condition which cuts off from the brain, or from a part of the brain, the normal supply of blood. This has now been proved by many cases in which ligatures have been placed for surgical purposes upon the common carotid artery, and in which the operation has been speedily followed by hemiplegia of the opposite side. I witnessed a case of this kind, in which, two days after the application of the ligature, the patient was suddenly seized with hemiplegia of the opposite side, without any loss of consciousness whatever, and in which the post-mortem examination showed a state of white softening of the cerebral hemisphere of the same side as that of the carotid tied. I myself put on record some years ago a case in which hemiplegia resulted from a state of white softening dependent upon defective blood supply, which I believe is perfectly unique; and, although I have many times tried to bring about this pathological condition by tying the carotids of the lower animals, I have never met with decided success; but in the case to which I am now alluding the experiment was already performed for us by what one may almost designate a *frank disease*. The case was one of dissecting aneurism: through a slit in the aorta blood in considerable

quantity forced its way, by splitting up the coats of this vessel along the innominate, and for about an inch and a half up the right common carotid, where it coagulated, and thus formed a plug, which completely obliterated the cavity of the artery (carotid); I should add, that the dissected condition of the coats extended downwards along the arch and abdominal aorta in the belly, to the renal artery. When the accident occurred the patient fainted, but he recovered after a little time, under the application of the usual restoratives; and I saw him the same evening, and also the following day, and was greatly puzzled to tell what was the nature of the case; for the principal symptom was pain, referred to the back and the chest. But two days after the accident the patient suddenly became hemiplegic on the left side, without in the least degree losing his consciousness; and the characters of the palsy were precisely those of our patient upstairs, the paralysed muscles being perfectly flaccid and relaxed. He continued, however, to live on for eleven days, a very unusual thing in a case of dissecting aneurism, and then death took place, the coats of the first portion of the aorta having given way, and allowed blood to escape into and distend the pericardial sac. When we came to examine the body, we found a state of white softening in all those parts of the right hemisphere of the brain which are supplied with blood by the anterior cerebral artery, which, as you know, supplies the whole substance of the hemisphere. I may here observe, that the chief reason why I have been unable to produce this condition in the lower animals by tying the common carotid artery, is that their brains receive their chief supply of blood from the vertebrals, which appears to be even sufficient to keep up its nutrition, when both carotids are perfectly obliterated.

The state of white softening of the brain occurs chiefly in persons advanced in life—from fifty to eighty years of age, and upwards. In these patients it appears to depend upon a gradual change which takes place, to a greater or less degree, in the coats of all the arteries of the body, but especially in those of the brain. This change, which is known generally under the term *atheroma*, consists in the deposition of earthy and fatty matter in the walls of the vessels, causing a degeneration of their tunics. Sometimes the deposits are confined to the larger vessels; sometimes the capillaries are diseased, and their muscular fibres have undergone fatty degeneration, as was first pointed out by Mr. Paget. The effect of these deposits is, that the capillary circulation throughout the brain becomes more or less impeded, being most so when there is most disease of the vessels. The brain substance, gradually becoming less and less perfectly nourished, passes into a softened state, and at length melts down. The solution of continuity of nerve fibres which thus occurs results in the effectual cutting off of all communication between the centre of volition and the opposite half of the body, and induces a state of hemiplegia. It is precisely this process which, I believe, has taken place in the subject of our remarks to-day. If, then, the malady be due to a diseased state of the arterial system, and especially to a fatty condition of the cerebral capillaries, the walls of which have scarcely strength enough left to retain the blood within them, it is quite clear that the lesion is essentially of an atrophic nature, and in no way due to any overflow of blood to the brain. And it is in cases of this kind that true apoplexy most frequently occurs—that is to say, in which blood in greater or less quantity becomes effused into the brain—and the blood thus poured out often ploughs up the surrounding nervous substance, so as to form a considerable cavity, in which the clot is contained.

How do we distinguish this apoplectic condition from simple softening? and how do we know that in the case of our patient, Mary Anne Godfrey, true apoplexy has not occurred? The reason why I say there is no effusion of blood in this case is, because a very small clot will almost invariably induce more or less of a comatose condition. A clot no larger than the end of one's little finger will generally give rise to a lethargic condition at least, if not to perfect coma; and this will usually be accompanied with more or less of snoring. When hemiplegia is dependent on a state of simple white softening, though the patient may for some time after the stroke be for a brief period unconscious, lethargic, and inclined to gape, yet there will be no prolonged loss of consciousness, and the intellect will generally recover itself perfectly—this last depending partly on the normal nutrition of the greatest portion of the affected hemisphere,

and partly upon the healthy state of the opposite hemisphere.

Again, (and here, in consequence of want of time, I must speak rather dogmatically, although these conclusions, I should tell you, are drawn from close clinical observation, together with the results of numerous post-mortem examinations,) if blood be effused into the brain, provided it encroaches on and more or less lacerates healthy brain, then there will be more or less resistance or rigidity of the palsied muscles, while if the clot be large the symptoms of coma will be very decided and prolonged; the patient will lie in a heavy sleep, from which he can be roused only with great difficulty, or, perhaps, not at all. On the other hand, when you come to the bed of a patient labouring under hemiplegia from simple white softening, you will find him, generally speaking, able to answer questions readily and rationally, although, in some cases, his speech may be "thick," according to the extent to which certain muscles of articulation and deglutition may have been affected, or to which the centre of emotion may have been involved, either by shock or actual disease. We conclude, therefore, that the hemiplegia in the woman upstairs depends upon an atrophic softening (white softening) of certain central parts in the left half of the brain.

The history of this patient affords confirmation to this diagnosis. There is an account of her having had two or three epileptic fits prior to the first attack, and it is not improbable that both it and the second attack were real epileptic fits, so that it is very likely that the hemiplegia, or rather the white softening upon which it depends, may be associated with the conditions which give rise to the epileptic paroxysms.

Taking then this view of the nature of the case, what treatment did we pursue? You have heard the remedies which were employed prior to the patient's admission into the Hospital; and you will now, perhaps, not be surprised to learn that the plan which we adopted was precisely the reverse of this. A general supporting plan of treatment was resorted to; at first ammonia and chloric ether were exhibited every four hours, and with these a little wine was given; and during the last few days the patient has been taking quinine. Now, if the hemiplegia depended upon any hyperæmic or plethoric condition, upon a too highly nourished state of brain, or upon the presence of too much blood within the cranium, no measures would, probably, have been productive of greater harm than those to which we have had recourse; but on the contrary, our patient is slowly and gradually improving; slight reflex actions are now capable of being excited in the paralysed leg, and this limb will, doubtless, be the first which will recover itself, after which the palsy will disappear from the face and tongue, and lastly from the arm, for this is the order in which the recovery of paralysed limbs generally occurs.

I may here state that when this woman was in the Hospital in 1850, for a similar attack of hemiplegia, the paralysis was on the *left* side, whereas it is now on the *right* side; and the treatment upon which she was then placed was exactly like the course which is now being pursued.

She left the Hospital then, perfectly well, and continued so, with the exception of her being almost constantly subject, in a greater or less degree, to rheumatic pains until the present attack.

It often happens in cases of hemiplegia dependent on white softening, that the patient recovers perfectly from the first attack, and, after a longer or shorter interval, gets another stroke of palsy; and this second seizure is rarely on the same side as the first. The reason of this appears to be, that the affection depends upon a diseased state of the blood-vessels, and that this last morbid condition is the result of a symmetrical process, affecting both sides of the brain alike, but as it does not generally proceed exactly *pari passu* on the two sides, it is usually found in a slightly more advanced stage on one than on the other. This is a most interesting pathological fact, as it well explains the point in the clinical history of those cases to which I have just adverted.

Some of you may ask, How does recovery take place in these cases, and what changes occur then in the softened parts of the brain? It is impossible, in the present state of knowledge, to speak upon this subject otherwise than speculatively. As regards the fatty and earthy degeneration of the coats of the blood-vessels, upon which depends the defective blood-supply which so often immediately induces the state of white softening, this, I should imagine, is a morbid condition

which never recovers itself; but although this is probably the case, still as the softening is generally due directly, as just said, to some stoppage of the circulation in the brain, to the plugging, or the obliteration by some means of some vessel, so it appears reasonable to suppose that in the cases of recovery a collateral circulation is established sufficient to restore and maintain the normal nutrition of the softened brain; just as occurs when the main artery of a limb is tied for surgical purposes. This appears to me to be the most reasonable explanation of these phenomena, the correctness of which further observation must determine; however this may be, I feel satisfied from clinical observation that this simple white softening is capable of being repaired. But in very many cases the process of repair does not take place, the brain-fibres remain inadequately nourished, and so the case proceeds from bad to worse; the paralysis never recovers itself, the temperature of the palsied limbs falls below the normal standard, and the paralysed parts suffer in their capillary circulation, and often in consequence become œdematous. It is not very uncommon to see patients suffering from paralysis dependent on an atrophic condition of the nervous centres, whose palsied limbs are perfectly dropsical, although there may be no œdema of any other part of the body.

It is quite unreasonable, therefore, to think of treating such cases as that of our patient upon any other than a supporting plan. What you should do is to endeavour to improve the condition of the blood, and uphold the strength of your patient in every way that his digestive power will permit. If you do this you need not look upon these cases as hopeless, as used frequently to be done in former years; for upon this plan you will often find that these patients will go on for months, or even years. You see the practice which I almost invariably pursue, and many of you well know that it is a very rare thing for us to get a post-mortem inspection in these cases, as, unfortunately for our scientific researches, these patients won't die. Although we do not effect more cures now than formerly, certainly our patients live longer, and we generally send them out of the Hospital in a comparatively much improved condition; and this, I sincerely believe, is mainly, if not entirely, due to our adopting a supporting plan of treatment.

---

THE ATTEMPT TO ASSASSINATE THE EMPEROR.—The explosive machines employed were very much the shape and size of a large fir-cone, the base, which by reason of its greater weight, (being at least three centimetres in thickness,) must receive the shock on falling, being connected by chimneys with fulminating capsules. The cavity of the bomb was filled with fulminate of mercury, the explosive power of which is said to be fifty times greater than that of gunpowder. The wounds inflicted by these agents presented some peculiarities, upon which M. Larrey recently commented. Most of them are small and superficial, some being so narrow that a common probe could not pass. Some are confined to the skin, while others reach as far as the muscles, being usually limited to the superficial layers of these. There is almost always only one aperture, but sometimes there are two, usually only five or six centimetres from each other. The communication between these is usually direct, though sometimes tortuous. The apertures are usually irregular and jagged. The projectiles extracted from the wounds, and those collected in large numbers in the clothes were generally very small, consisting of angular, irregular toothed fragments of the shell of the bomb. The number of wounds received by the same person is remarkable, 27 being counted in one case—the lower extremities being usually the parts struck. Of little account at first, these wounds after some hours became more painful than their size would lead us to expect, owing probably to the narrowness of the track. There has been little hæmorrhage; and the inflammation and fever have been very slight, while there is an absence of the nervous stupor or agitation seen in ordinary gun-shot wounds. In a few cases large pieces have produced far more serious effects, either causing death by penetrating important viscera, or producing the ordinary effects of gun-shot wounds. The great number and relative mildness of most of the wounds received, is due in great measure to the anxiety of the assassins to make sure of their aim. The fulminate by the violence of its action, so to say, crumbled up the machine in place of splitting it into splinters.

## ORIGINAL COMMUNICATIONS.

## THE PHYSIOGNOMY OF INSANITY.

By JOHN CONOLLY, M.D. D.C.L.  
Consulting Physician to the Hanwell Asylum.

## No. 3.—GENERAL MELANCHOLIA.

ONE effect of looking attentively at the portraits of the insane, when faithfully represented, is that the image remains long in the mind, with all that it reveals of the patient's state and antecedent experience; and that reflections naturally follow, touching the life of those consigned to this dreadful affliction, both before it fell upon them and after their recovery. For with them, the end of their mental trouble is often but the beginning or renewal of other troubles, many and great. The misanthropic poet, entranced with the grandeur of nature as displayed in all the beauty of mountain and lake, and all the variety of sunshine and storm, laments that he must plunge again into the crowd of mankind; and, though young, feels morbidly the loss of friends by whose death he seems to be left alone on earth. Yet he has wealth and rank and fame to support him. The poor recovered lunatic goes out of a comfortable asylum, to mingle with men once more; to seek his dismantled lodging; to meet his half-famished wife; to hear of the wanderings or the vices of his neglected boys; of the misery of his girls; and to encounter once more a world of want and hunger—of life-long "looped and windowed raggedness;" and of labour for which years and sickness have almost unfitted him.

The photographic portraits presented to the reader being chiefly of the poorest persons in society, naturally turn the thoughts towards the causes, forms, and consequences of insanity among those who must work for their daily bread, or have none. In the ranks of poverty we can conceive the exhaustion of hope, the miserable downward prospect of age, and, withal, the failure of energy in a poorly nourished brain. But insanity betrays the secret history of rich houses also, and exemplifies, in countless instances, the existence, even under their imposing covering, of all the feelings which lead to despair. The splendour fades when the house contains one member of the family whose mind has given way. Vast halls, and long silent galleries, and stately apartments, of which all the showy uses are gone, reveal to the Medical observer the nothingness of station and wealth, and the intrusion under golden roofs of all disturbances of mind, great and small, aspiring or mean. Surveying, even in a journey, the exterior of great mansions, in situations of matchless beauty—the grand portico, the vast range of windows, the surrounding plantations, the very trees of which seem aristocratic—one piece of fatal knowledge touching the wildness, or gloom, or imbecility of the owner, who lives in the mansion unconscious of all the high privileges which his gifts of fortune would bring with them, and having nothing mental left but the wayward caprice or frivolous joy of a child, throws an air of sadness over all the scene, casts a shadow over the sunny lawn, and gives a browner horror to the woods surrounding a house which has become a mere mausoleum of an owner dead in mind.

So, even the life-reflecting photographs of the insane, produced by Dr. Diamond, and copied to aid imperfect verbal description, cannot be viewed by those unfamiliar with faces and figures under the impression of desponding malady without feelings which become suggestive of many painful reflections. The equal step of affliction is traced in the castle and the cottage. The one accompanying the present paper is peculiarly of a character to excite the sympathy of any reflecting person who considers it. By some misfortune, a few of the most expressive points in the photograph are lost in the present Engraving; so that my description, written with the photograph before me, may seem exaggerated; whereas it is a faithful transcript from a faithful copy of the living man. A good disposition, free from violence or vice, together with habits of patient labour, seem clearly depicted in it; but the poor man's toil of limb and hand has visibly ceased. His frame is wasted, and the energy of the brain is no more equal to sustaining the limited exertion

of a day-labourer's life. The muscles are shrunken; the coat and waistcoat hang about him, in no way fitting him and his trowsers are a world too wide. The very integuments of the hands show, by numerous wrinkles, that nutrition is languid; and the whole figure indicates that the brain has suffered in the same way—is ill nourished, perhaps wasted in substance also, and shrunken from the skull. And hope and cheerfulness have departed from the poor man's heart altogether.

There is a curious kind of family resemblance in all these cases. Many a superintendent of an asylum, looking at this portrait, will be inclined to think he remembers such a man having been under his own care. I am myself very forcibly reminded by these photographic pictures of many cases familiar to me in the wards of Hanwell, in years gone by. Hopeless and worn out men, and desponding and terrified women, constituted a considerable proportion of the cases admitted from distant workhouses or from homes of destitution. In many instances such a state was but a painful ending of a life of joyless struggle. The female patients, in whom melancholia had often supervened on bodily illness, recovered in time, in larger proportion than the men. The women were usually more imaginative, and their fears were more various. In the men, depression seemed to have grown gradually out of realities; out of the hopelessness of overcoming the perpetual enemy with which they had honestly contended almost from boyhood to middle age; and, when once overcome, they rallied no more. The enemy was poverty.

Such are some of the melancholy results incidental to present social arrangements, and perhaps never to be quite unknown. But to those acquainted with the interior of the many good asylums in which these broken down people find a refuge and a rest on this side of the grave, the contemplation of them, and the pictorial representations of the visible effects of their various forms of distress, are not productive of pain without mitigation; for they know that even among cases the most hopeless, there are few incapable of being alleviated. Many must be the recollections of such in all asylums, for the class of paupers especially. Many a time, in all such institutions, have poor creatures arrived in carts; bundled up in wretched coverings; haggard and wild in aspect; regarding everything and everybody with suspicion, and seeming incapable of comprehending kind words, if such words were addressed to their unwonted ears. They entered the doors of the asylum as if they were entering a prison or a place of torture; looking at every stair and every side-passage with doubt and dread; ready to start away, anywhere—where; uttering few or no words, and those only of apprehension. Food was placed before them; but they could not, or they would not, eat. Their squalid clothes were removed; they were washed, or, for the first time since they were infants, were put into a warm bath; and then seated in clean and orderly wards, or taken to comfortable sleeping rooms; where for a time they could not be persuaded to lie down; for the very novelty of cleanliness and carefulness bewildered them. They had lived so long in a friendless world, that the language and actions of kindness were to them strange and incomprehensible. They could not understand the various attentions they received; and if they thought at all, thought they must be in a dream of what, contrasted with their habitual condition, must be a state of greatness such as dreams invent. And yet, although it was sometimes long before all the kindness that could be shown to them seemed to find its way to the heart, it usually did so at last: for true kindness is all-powerful. So, in the end, the unremitting attentions of many kind persons scarcely ever failed to awaken the dormant sympathies of these poor melancholy patients. Oftentimes the attempt appeared at first hopeless. Reasoning and expostulation were of no avail; and any appearance of authority only created fresh difficulties. In the old times, the refusal of food was opposed by force; and the patients, as the records of the asylum show, where any records exist, usually died. If the patient was suicidal, or destructive, or troublesome, the strait-waistcoat, or handcuffs, or hobbles were resorted to, and worn in many instances for years, and sometimes, as I have myself seen, to the hour of death itself.

In those times, the galleries and cells of asylums presented vivid expressions of malady to the artist: such as now will be looked for in vain. It was not simple malady indeed which was generally depicted in the faces of the wretched people

who then raved or moped in such places; but malady aggravated by mechanical coercion, or by neglect, or by positive cruelty. If none of these direct aggravations of disordered mind had been experienced, the faculties of the patients, generally, had been left quite unregarded and unemployed; so that the morbid ideas, the extravagances, or the listless apathy of the patients were left quite uncontrolled. The illustrations of insanity published from life at that time, often show these peculiarities in an unmistakable manner, as well as the mechanical means productive of them.

When those harsh practices prevailed, little or no attention seems to have been paid by the superintendents of asylums to the various shades of character of the patients admitted.

Generally, the history of the cases was neither recorded nor medically inquired into. Some cases were set down as violent, some as melancholy, some as suicidal, and some as harmless. The last alone were permitted to have the free use of their arms or legs; and were generally neglected. It is a part of the new system to examine every newly admitted case minutely; both as respects the mind and the body. The previous life is compassionately considered; the defective education, the privations, the scanty nourishment, the misfortunes; and all the influences which, long acting on the body and the mind, have produced exasperation, or terror, or despair, are not forgotten. And these considerations furnish indications of treatment, by following which the modern guardians of the insane have been enabled to increase the number of cures, and to diminish the number of deaths.

All the attentions alluded to, acting variously but continually, and combined with inexhaustible patience, communicate, at length, confidence, and even hope, to the poorest and unhappiest of people in good asylums. In some the change may be but slightly indicated; by a smile perhaps, or by an offered hand; but stronger indications will follow; industry will be resumed; and the most torturing features of the malady will disappear. Of patients of this kind, of the poorer classes, those are doubtless most secure of continued comfort who never afterward leave the asylum. Some of these I well remember who fully appreciated the haven in which they felt no more the storms of life; and who, remaining there until existence came to its natural close, earnestly requested to be buried in the quiet grave-yard of the asylum. Others, recovered enough to depart, and urged to departure by the destitute state of their once abandoned children, left the asylum with reluctance, with grateful expressions, and sometimes with tears. They had too much reason to do so; for when the gates closed after them, the hard world of trial again awaited them. Descriptions of such cases would be little better than vain recollections, but for the practical lessons taught by them, of the advantage, even among the insane, of considering the capacities and requirements of human beings, so as to act favourably upon them. This is really done in asylums; but scarcely anywhere else.

Sometimes the subsequent lot of such recovered patients comes distinctly to light. A few months since, I visited a poor married woman in one of the best Union houses near London. I went because I heard that a maniacal woman there was always praying to be sent to Hanwell. She was, however, scarcely to be recognised. Thirteen years, or thereabouts, had passed over her head and mine since she had left Hanwell, fully recovered from suicidal melancholy. Being then young, and her appearance prepossessing, and her disposition very amiable, she was an object of great interest to everybody in the establishment. Since that time she married, and has had five children. Until lately she continued quite well. Her husband is a hairdresser, and they seem to have lived happily together. Some months ago, their house took fire, and they lost all their little possessions. Not long afterward one of their children died—a very interesting little girl, and very dear to them. After that, the poor mother, who grieved much, began now and then to manifest some agitation of manner or weakness of mind. About ten days before I saw her, it happened, singularly and unfortunately, that the house of an opposite neighbour took fire, and the poor burnt-out inmates were hospitably taken in by this equally poor and half-distracted mother and her husband. This accident, however, and the recollections it revived, brought on a decided attack of mania, in which she became dangerous to herself and others. In this second attack, and in the midst of her incoherent talk, she still remembered Hanwell, and much that had occurred there, including having

there had her likeness taken. There was no room for her at Hanwell, and no room at Colney Hatch; both these large asylums were full. She could not be taken care of at home, and the Union was the only resource. There she was kindly received, and humanely attended to, as far as the arrangements could permit. But she was observed to be suicidal, and even now and then violent towards others; and she was almost of necessity put into a dress with long sleeves, preventing motion of the arms. She was also placed in a padded room, in which there was just space for a person to stand between the bed and the door, and to which there was no window. Air was admitted through a small grating in the door, and there was a perforated circle in the top of the room, the room itself not being so high as the ceiling, and being indeed only a closet within a room. When the door was shut the patient could not be seen. The door was secured by two large prison-bolts. Although the poor woman talked quietly, and sat down by the bed and sang some old songs sweetly, the nurses were still afraid of her, and the restraint in which she was placed seemed to them to be unavoidable. At Hanwell she would have been walking about in the wards, carefully watched; or, if in a padded room, not in darkness or close air. The restraint resorted to in the Union was irritating to the body and mind, entirely opposed to cleanliness, and calculated to oppose every attempt at cure. If it had been continued the patient could scarcely have recovered; and, in all probability, she would have died. It is in such cases and circumstances that we learn to appreciate the blessing of having in each county an asylum which affords a real place of refuge; for it is in vain to deny, and it would be folly to forget, that there was a time when institutions for the reception of pauper lunatics merely offered the convenience of relieving the workhouse; and possessed neither superior comforts, nor more chances of recovery than workhouses far more miserable than workhouses themselves now are. Not long after my visit, this poor woman was happily admitted into the Hanwell Asylum, where she is recovering.

The modern artist and the photographer are enabled to represent true pictures of what is effected by mental malady, and to facilitate the knowledge of its association with bodily ailment or disturbance, capable of relief. In the engraving No. 1 the deep perplexity of the young religious woman was unmingled with any trace of horror. In No. 2 the terror was of injury from imaginary beings. In No. 3 simple despondency is expressed, arising from failing powers of health, and the prospect of old age and poverty. Violent coercion would have added the expression of torture and vengeance to that of religious scruples and fear in the first illustration; would have exasperated that of the second into something demoniacal; and have added anguish and bitterness to the calm and resigned, though melancholy look of that which appears in the present number.

If I may trust to a general recollection of melancholic cases both among the poor and the rich, I should say that the number of cases in women considerably exceeds that of the supervention of the malady in men; and that in men it more resembles a deeper shade of natural anxiety arising out of real causes. It is less discursive, and generally less fruitful of various horrors in men than in women. Cases undoubtedly occur, in young men, of real acute melancholy, and are temporary in their duration. Such cases very commonly originate in irregular habits of life, coupled with the unstified voice of conscience. But by far the greater number of examples in male subjects will be found to be presented in middle and more advanced age, arising out of the continued cares and anxieties of life, and the fainter and fainter colouring of hope. And these cases are for the most part suicidal. I have known some such within the circle of my own private acquaintance; and in all, when their circumstances were minutely examined into, there had been some unexpected loss of property, or some concealed embarrassments. The older such patients are, the less expectation can be entertained of their recovery of mental energy. Indeed, many cases called cases of melancholia in young men, are but the beginning of a general loss of mental power, which passes on after the first delirious outbreak to imbecility, and gradually to dementia; and in older men the melancholy is often the mere commencement of senile decline. The malady is also in men more generally hereditary.

The Illustration No. 1 is most conformable to the characteristics ascribed to the melancholic temperament, being

marked not only by the black hair and eyes so frequent in melancholic patients, but by the long neck, expanded forehead, and other peculiarities often assigned to this temperament. I have met, however, with very intense cases of melancholia in young, fair-haired women; and although usually a dark-coloured skin is observed in the unhappy subjects of this malady, it is scarcely so constant as to justify a positive theory founded on the mere alteration of the secretion of bile. Remarkable modifications of the renal secretion often exist, without any other very manifest physical derangement. The countenance of men thus affected is peculiar: there is no trace of fancy or of disordered imagination, but a solemnity which scarcely admits the possibility of a smile. If a smile is evoked, it is in such a sort as to be really painful to behold.

The subject of the Illustration accompanying the present paper is one presenting the kind of solemn hopelessness arising out of long and unavailing efforts to keep just above poverty; and out of the diminution of nervous energy which becomes generally perceptible in the working man at his time of life. Probably both circumstances conjoined have brought him to this. He is sixty years old, and has all his life been a working gardener; sober in his habits, conducting himself well in the affairs of life, and reported to be of pleasant manners. But, although his occupation was one which a great authority declares to be the purest of human pleasures, and the greatest refreshment to the spirits of man, it could not ward off the invasion of slowly and obscurely working causes of decay. His power of being industrious died away; his pleasant manners left him; and some months since he fell unaccountably into a state of apathy or of vague despondency; his silence only broken by moaning and lamentation; and yet retaining a capability of making a rational reply to words directly addressed to him. The good form of the head; the shape, especially, of the anterior and upper head, and the submissive expression of the features, where we find no trace of violent passions or of evil habits, are distinctly marked. We read the clear impress in the whole face of an honest man. But the eye is sunken into the socket; the grey hair hangs straight, as is usual in age; and, although he is not very far advanced in years, the withered frame and settled hopeless look, and the general expression and attitude; the drooping head, the sight unemphatic on surrounding objects, the hands resting on the thighs, and the mental revelations of the eyelids, and of the forehead, and of the protruded under-lip; with the line drawn from the angle of the nose to the mouth, as well that line of age and care drawing down the corner of the mouth itself: all convey to the student of the human face, that, with failing nutrition hope has failed also; that the patient has come to a conclusion that insuperable trouble has fallen upon him, and that, ever meditating upon this, still he finds no way to escape. Dulness, therefore, the advancing shadow of the dulness of death, rests upon him, never in this world to be withdrawn.

#### NOTES OF

### PRACTICE AMONG THE OUT-PATIENTS OF ST. BARTHOLOMEW'S HOSPITAL.

By JAMES PAGET, F.R.S.

Assistant-Surgeon to the Hospital.

(Continued from page 5.)

#### NO. II.—ON SOME AFFECTIONS OF THE MOUTH AND FAUCES.

*Enlarged Tonsils.*—There is a physiognomy by which the children and young people that have simple enlargement of the tonsils may usually be known at once. Together with a general appearance of feeble health, they have a peculiar shape of the mouth and jaws. The jaws are narrow, so that the teeth are crowded and look disproportionately large. The aperture of the mouth is small, habitually slightly open; the edges of the lips thick, but not pouting, the lower lip rather inverted; the angles of the mouth a little raised; the front of the mouth is almost uniformly convex; the lower lip scarcely recedes towards the chin, but projects with a

broad convexity, as if its middle part were slightly pushed forward by the tip of the tongue. The general expression is that of a gradual narrowing and a smooth uniform rounding of the lower part of the face, which make it look small and featureless.

These peculiarities of shape appear due, partly to defective growth of the jaws, and partly to the habit which the patients have of advancing the lower jaw and tongue, in the position in which these parts are yet more evidently held during acute inflammation of the tonsils.

*Supernumerary Tonsils.*—I have twice seen a supernumerary tonsil (or what looked exactly like one) under the mucous membrane of the back part of the pharynx. One of the patients was a child, eight years old, with enlarged tonsils. Behind the mucous membrane, in the median line of the back of the pharynx, there was a firm, circumscribed oval mass, about half-an-inch in chief diameter, feeling exactly like a tonsil, and covered with healthy, but granulated mucous membrane. The other patient was a lady, twenty-five years old, in whom a similar swelling, exactly like a tonsil uplifting the mucous membrane of the pharynx, was situated just behind the right posterior arch of the palate. Six months after I first saw it it was scarcely discernible.

I have not had an opportunity of proving, by dissection whether my belief that these swellings were tonsils is well-founded, and I am not acquainted with any description of supernumerary tonsils. But when we consider the varieties of size which the ordinary tonsils present, independent of disease, in different persons, and the still greater differences of development of the similar follicular structures at the root of the tongue, we may believe that few organs are more likely than the tonsils to have outlying masses of structure like their own in their close neighbourhood.

*Excision of enlarged Tonsils.*—For chronic enlargement of the tonsils, whether through simple over-growth or in consequence of chronic inflammation, the excision of the projecting portions seems by far the best treatment. So far as I have seen, the cutting of tonsils is never followed by severe hæmorrhage or other serious inconvenience, provided they are not inflamed at the time of being cut. And I believe that if other means of reducing the size of enlarged tonsils be not quickly beneficial, the excision should be adopted both oftener and earlier than it commonly is. One frequently sees cases in which delay in operating has given time for the occurrence of the incurable "chicken-breast"-deformity of the chest, which Dr. Warren pointed out as a common result of the habitual hard breathing of children with enlarged tonsils.

The double vulsellum and common probe-pointed bistoury are, I believe, the most advisable instruments for this operation, because, among other reasons, they are equally fit for all cases. There are certainly some cases for which even the most improved guillotines are insufficient instruments; those, namely, in which the enlargement of the tonsil extends so far down by the side of the pharynx, or up towards the soft palate, that a fair portion of the disease cannot be taken within the ring or loop of the guillotine. For these broad-based enlarged tonsils, the knife alone is applicable; and, to remove them effectually, it is advisable to have a facility which will hardly be possessed if the knife be used for them alone, but which the hands accustomed to the cutting of common enlarged tonsils will seldom lack. The general direction for the operation must be to cut from below upwards, the blunted point of the knife being carried well backwards, and its edge just internal to the posterior arch of the palate.

*Salivation.*—Cases of salivation usually recover more quickly and more favourably among out-patients than among in-patients; for the freer exposure of the former to the outer air seems to do even more than compensate for the want of the comforts provided for the latter in the Hospital wards. I have, indeed, seen no cases of the severest salivation among out-patients, probably because I have never prescribed large quantities of mercury, and have never had the mishap of falling in with those whom even small quantities will severely affect. Among out-patients, no treatment of salivation has seemed so rapidly beneficial as that of giving saline purgatives (such as a Hospital mixture, with a drachm of sulphate of magnesia and ten drops of diluted sulphuric acid, three times a-day), and washing the mouth frequently with a

gargle containing either one or two grains of sulphate of copper in the ounce of water. Almost always, in three or four days of such treatment, all the severity, if not all the appearance, of the salivation is gone. Very free action of the intestines should be induced and maintained; for, except renal disease, nothing appears more favourable to the bad influence of mercury than constipation. It will be observed as having preceded nearly all unexpected or too severe salivations.

I have been told that the internal use of small doses of sulphate of copper is as beneficial in salivation as its external use; but in a few trials which I made with it, it appeared without influence.

*Perforating Ulcers of the Palate.—Inherited Syphilis.*—Cases are not very rare in which all the appearances of a tertiary syphilitic disease are seen in persons who have never had primary syphilis, and some of whom have never had sexual intercourse. Among such patients, I have seen cases of ulceration and necrosis of the bones of the skull, of iritis, of phagedenic ulcers of the extremities, the tongue, the palate, and the pharynx, which I could not by any characters distinguish from the ordinary tertiary diseases of the same parts, but which were certainly not preceded by any primary symptoms in the patients themselves.

I believe the explanation of such cases to be, that the patients were born of syphilitic parents, from whom they inherited a taint, of which the manifestation was delayed or renewed many years after the ordinary times of appearance of inherited syphilis. In some instances, I have known that the parents of such patients were syphilitic after marriage, and, in some, that the patients themselves had had infantile syphilis, from which they appeared to have completely recovered for ten or twenty years before the disease resembling tertiary syphilis appeared.

This manner of the appearance of inherited syphilis is not commonly admitted or thought of. And yet it is a very probable one, being much more according to the general rules of the inheritance of diseases, than is the almost unique method which is evident in infantile syphilis. Gout, phthisis, insanity, cancer, and other diseases, when they pass by inheritance, very rarely appear in infancy or early childhood; the general law of these inheritances is, that the manifestation of disease in the offspring should appear at or near the same time of life as in the parent. The transmission of syphilis is rarely according to this rule; but we should expect that the rule would, sometimes, be so far observed as that the disease should not appear till puberty or later; and such an accordance with the general rule is, I believe, exemplified in the instances above referred to.

Among the diseases which I am disposed to refer, in some cases, to this inheritance and late manifestation of syphilis, is a form of perforating ulcers of the soft palate which, I believe, has been too little noticed. It occurs most frequently in girls and women, especially (but not exclusively) in those who are ill-fed, or, from other causes, anæmic. It is sometimes associated with destructive ulceration, like that of lupus, in the nasal cavities, or fauces, but is more frequently the sole local disease. In some patients it follows other manifestations of syphilis; but in the majority no history of syphilis can be traced.

The edges of the ulcer, in any of these cases, are sharp and abrupt. They, and its base, are covered (while it is in progress) with an ashy or yellowish layer, as if with a superficial slough, and they are surrounded by a bright red area of highly vascular mucous membrane. The progress of the ulcer is scarcely painful; but in one or in two weeks it may perforate the whole thickness of the palate, boring a round or oval hole through it, or (if reaching its posterior border), making a wide gap, or destroying some of its border, or of the uvula. The borders of the ulcer are not indurated, and it heals with a smooth, thin-edged, glistening scar.

As I have already said, it is not pretended, and cannot be proved, that such ulcers of the palate as these are always, or generally, due to inherited syphilis. But in some cases I believe they are so; and the belief is strengthened by their being so generally curable with iodide of potassium, which leads to their speedy healing, just as it does to that of the known tertiary syphilitic ulcers, and as it does not to that of the ulcers due to lupus, or to tuberculous or strumous diseases.

## CASE OF TETANUS,

By JOHN W. GOODWIN, M.D.

Physician to the Norfolk and Norwich Hospital.

A. F., aged 19, a strong, healthy young woman, had been married about a month, and had always enjoyed most excellent health: was admitted into the Norfolk and Norwich Hospital on Tuesday, Jan. 19th, 1858, at 4.30 p. m. The following history was furnished by her husband. On Saturday the 16th Jan. she complained of pain in the chest, as if she had a cold, which continued to increase all Sunday, with slight pain in the side. On Monday she complained that the pain had removed to her neck, which was rather stiff, and at night had a warm bath and took a basin of gruel before going to bed about 10 o'clock, when she asked for a piece of bread, but could not eat it. From this time the pain and stiffness increased, and frequent twitching came on, which by 3 o'clock a. m. on Tuesday morning seemed to "chuck" her out of bed almost, so that she had constantly to be laid on her pillow; her back was very stiff, and her jaws were so fixed that when he left at 6 a. m. to go to his work, he did not think a sixpence could have been got between her teeth. The husband also stated that about three months ago, in carrying a weight up some steps she struck the right shin against one of the steps, which was bruised slightly and was tender for a short time; there was also a substance the size of a large pea or small bean to be felt in the situation of the bruise, which could be moved freely about, and which he last felt about a week previous to her being taken ill; it was tender if touched upon the top, but not if taken hold of and moved about. Mr. Francis, the district surgeon, was summoned to see her about 11.30 on the 19th, and found her bathed in profuse perspiration and labouring under constant short and severe spasms of the muscles of face and neck; the back was very rigid, and the hand could readily be passed underneath her; jaws firmly locked, and teeth, which were very perfect, close together, without leaving the least aperture. Partial pleurosthotonos was present. He administered a turpentine enema, which brought away a large quantity of flatus and some offensive fecal matter, and recommended the immediate removal to the Hospital.

On her arrival at the Hospital I found her very cold and exhausted, and there was great congestion of the face and upper extremities. Her breathing was gasping, forced, and hurried. The spasms were rapidly recurring in the muscles of the neck and chest. The back was quite rigid, and the muscles of the extremities were occasionally involved in the spasm. I immediately administered chloroform by inhalation, which had present and marked effect in relieving the spasm, and causing her to breathe evenly and quietly. The pulse, which on her admission was too quick to count, and most feeble, became about 110 to 120, and was fuller and stronger. Her skin became warm, and the fearful expression of countenance was replaced by a calm and tranquil appearance. The spasms recurred, however, very quickly if the effect of chloroform at all wore off, and I directed it to be continued constantly. I gave her two drops of castor-oil in a suppository, and a drop was also placed on the tongue by an elastic tube, when the spasm was slightly relaxed in the muscles of the jaws. Ice was also applied in bladders to her spine, and I left her at about 5.30, with the intention of returning at seven to see her. She, however, died suddenly, just at seven o'clock. The House-Surgeon had continued the administration of chloroform with good effect, and she had been so free from all spasm for about a quarter of an hour, that he felt quite encouraged when, after making an effort to speak, a sudden severe spasm seized her, and she was dead almost instantaneously. I forgot to mention that the catamenia had been present normally for three days previous to, and were so at her decease.

*An examination was made sixteen hours after death.*—There was no unusual cadaveric rigidity, and the muscular development was large, the body appearing well nourished. The brain and membranes seemed perfectly normal, but it was considered that the vessels of the membranes of the cord, and the cord itself, were rather more injected than usual. Lungs and heart were perfectly healthy, with the exception of a patch of pleuritic adhesions, quite recent, just about the middle of the anterior surface of the right lung. The stomach contained about half an ounce of fluid, which has not yet been

tested chemically. The uterus and ovaries presented the usual appearances seen in the bodies of women who have died menstruating, the uterus being enlarged, and containing several bullæ. The uterus itself contained a small coagulum. Not any other abnormal appearance could be found, and no trace of bruise on the moveable substance on the shin-bone, as described by the husband.

This extremely rapid case appears to me to fall into the list of those rare cases of *idiopathic* tetanus, at least rare in this climate. There is no ground whatever for any suspicion of poisoning, and I should not be inclined to attach much importance to the injury alleged to have taken place on the shin bone as a cause in any way of the disease. I would rather look upon it as having its origin in exposure to cold. As to the predisposing causes I fear, as is usual in such cases, little can be adduced, and this case does not furnish, more than preceding ones have done, any explanation of what the peculiar condition of the nervous centres necessary for the development of tetanus may be. In Dr. Todd's words, the immediate exciting cause, and the detail of the symptoms, constitute the entire history of the case.

Queen-street, Norwich.

## TREATMENT OF HERNIA BY WUTZER'S APPARATUS.

By ARTHUR J. CUMMING, Esq. M.R.C.S.

A boy, 12 years of age, was admitted an out-patient of the Exeter Dispensary in the beginning of this month, with a very large scrotal hernia (congenital), a bad cough, and rather weak intellect. He was fitted by a good truss-maker here, and although the truss was very strong, the hernia could not be kept up. On the 8th instant, I applied Wutzer's apparatus, which was kept on until the 14th instant, when the parts became painful, and inclined to suppurate; I therefore removed the plug and applied the truss, which before had failed to keep the rupture up. During the removal of the apparatus the boy coughed and cried violently, but the parts remained firm, and continue to do so.

I have now little doubt a cure is effected. There has been no constitutional derangement, and comparatively little pain.

I think an important part of the operation is to get the plug well beyond the internal ring, so that the needle may hold some of the tendinous fibres.

This appears a very good trial for the apparatus. I will communicate further, should there be any return of the hernia.

Southernhay, Exeter, Dec. 21, 1887.

## THE LONDON PRACTICE OF MEDICINE AND SURGERY.

### THE CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST. ILLUSTRATIONS OF THE TREATMENT OF THROAT AFFECTIONS.

(Cases under the care of Drs. PEACOCK, BENNETT, and BIRKETT.

(Continued from page 118.)

CONTINUING the examples of the usefulness of counter-irritation in catarrhal aphonia by the strong solution of iodine, we may cite the following, in which an affection of two months' standing was nearly cured by a single application. Its evidence is important also because sinapisms had previously been used without material benefit.

*Case 13.—Catarrhal Aphonia of two months' duration.—Cure by the topical use of iodine-counter-irritation.*—Elizabeth Mellish, a married woman, aged 39, stout and florid, was admitted under Dr. Birkett's care on Oct. 26. She stated that during a severe cold, two months before, she had become hoarse, and the symptoms had since increased. For more than a month the affection had been persistent as at present. Her voice was all but lost, and when produced was very hoarse and rough; the cough was also hoarse. There was no pain in

swallowing. The pharynx was pale and smooth. Two sharp mustard plasters had been applied, but without any relief. Dr. Birkett ordered a demulcent mixture for the cough, and directed that the iodine solution should be applied outside the throat. The painting was made very freely.

On Nov. 2, a week after the application, her voice was very much stronger, and the hoarseness less. On the 9th the throat affection was all but well. She remained under care on account of a bronchitic affection for a month longer, but excepting the first painting no topical measures for the throat were needed. Her voice remained clear, though slightly feeble. She was discharged well on Jan. 25.

We have adverted to the frequency with which slight laryngeal affections in delicate women occasion a loss of voice, which, if not actually deserving the name of hysterical aphonia, is closely dependent upon a hyper-susceptibility of the nervous system. The following case is an example of pure hysterical aphonia, in which probably not the slightest of inflammation of the laryngeal mucous membrane existed.

*Case 14.—Hysterical Aphonia.—Somnambulism.—Throat hæmoptysis.—Treatment without any topical application.*—Rachel N., aged 18, a tall slender girl, of intelligent expression, who had been in training as a pupil teacher, was admitted on August 17, under Dr. Risdon Bennett's care. Her deportment and expression were very markedly hysterical. She had considered herself in consumption, and had acted the part of a confirmed invalid for nearly two years, during which time she had wearied out the patience of several Physicians at Hospitals where she had attended. Her cough, a loud ringing one, like the bark of a weak-voiced cur, was made to resound through the house whilst she was sitting in the waiting-room. Judging from its character, a very hoarse voice might have been expected. It was not so, however; quite inconsistently, the voice was the faintest possible whisper, but perfectly free from roughness. Her aspect was not phthisical, nor had she materially lost flesh. There had been hæmoptysis in very small quantities several times; but in all probability the blood had come from the throat, the artificial violence of her cough being quite sufficient to account for the occasional rupture of small vessels. It was stated, however, that some of her mother's family had died of phthisis; that disease had, however, not shown itself in any of her brothers or sisters. Her mother stated that she was a very restless sleeper, and had frequently been known to walk in her dreams. On careful examination of the chest, no physical signs of importance could be detected. The catamenia were reported to be irregular and painful. The urine was pale, copious, slightly turbid, not coagulable, and of sp. gr. 1015.

The diagnosis as to the absence of any real disease was so positive, that no local treatment was thought of. Dr. Bennett contented himself with ordering the tincture of valerian in a stomachic and tonic mixture, and giving directions to her mother as to the requisite moral management. It should be stated that, as is often noticed in the more severe forms of hysterical simulation of organic diseases, that no actual hysterical fits had ever been known to occur. The girl continued to attend for about two months, and then left to go into the country. The symptoms had been very little influenced.

The four cases with which we shall conclude this series, are examples of the loss of voice in connexion with tumours in the neck. By far the more common of the tumours met with in this region are enlargements of the thyroid body, but aneurisms, malignant growths, and swollen lymphatic glands, are equally potent in their influence upon the larynx, and, from usually being concealed, are of much more difficult recognition. A specimen of aneurism of the aorta, presented to the Pathological Society by Mr. Childs at a recent meeting, was from a case in which tracheotomy had actually been performed on account of symptoms of laryngeal obstruction; and we well remember an almost similar one in which Mr. Le Gros Clark performed in St. Thomas's Hospital the same operation when the real cause of the dyspnoea was an aneurism within the thorax. It is often exceedingly difficult if not impossible to discover at what part of its course the trachea is obstructed, or whether the cause of the dyspnoea exists in it or in the larynx. In association with tumours the breathing is impeded from two quite different causes: first, the trachea itself may be compressed and narrowed; and secondly, the laryngeal nerves, and especially the recurrent, may be stretched, pressed upon, or otherwise irritated, in-

ducing spasmodic closure of the glottis. To the relief of the latter element, tracheotomy is an effectual measure, but it usually can do nothing against the former. Not unfrequently both are in action in the same case, and a permanent dyspnoea is present, induced by the compression of the trachea, whilst there is also a liability to suffocative paroxysms due to irritation of the nerves. In none of the forms of chronic laryngitis, as illustrated by the preceding cases, is there any liability to marked paroxysmal aggravation, and in this symptom we have a most useful diagnostic of the probable existence of a tumour.

*Case 15.—Permanent and paroxysmal Dyspnoea, dependent upon a tumour in the right side of the throat.—Some relief by Counter-irritants.*—A man, aged 30, attended Dr. Peacock's out-patients' room for some months on account of hoarseness and loss of voice of long duration. His voice was metallic and ringing. He looked ill, and there was considerable lividity of the lips. In the right side of the neck a little above the clavicle was an oval tumour evidently of deep attachments, and about the size of a small fist. It fluctuated indistinctly, and was diagnosed as a tense walled cyst. There had been paroxysms of dyspnoea in which suffocation had appeared imminent. Mr. Hilton saw the case in consultation with Dr. Peacock, and as no surgical interference was thought advisable, it was determined to try the effect of severe counter-irritation over the tumour. The tumour, it should be stated, had existed for many years, but had latterly increased. It did not appear that there was any very great pressure upon the trachea itself, as the opposite side of the neck was quite free.

Counter-irritation, by means of the iodine paint, and also of a very strong solution of nitrate of silver with nitric acid was repeatedly resorted to during a period of about three months. After each application the tumour became less tense and softer, and the symptoms were notably ameliorated. Although it gave intense pain the man was always anxious to have the application made. At length the voice was very much improved, and the liability to paroxysms passed off. The man left town to go to the sea-side, and nothing was subsequently heard of him.

*Case 16.—Large Bronchocoele.—Hoarseness and Dyspnoea.—Liability to Paroxysms.—Recovery under Iodine Treatment.*—Ann Moszis, aged 15, for three years the subject of a large bronchocoele, was admitted June 8, 1883, under the care of Dr. Birkett. Her maternal grandmother, two sons, and two sisters were stated to have had full-necks, but had all recovered from the affection. The tumour was a large one, and almost of equal size on the two sides. She had been very hoarse for many months, and suffered constantly from impeded breathing. Paroxysms of dyspnoea had often occurred, but had never been very severe. Menstruation was reported free and regular. The girl had been born and brought up in Essex, but for four years past had lived in London.

A mixture, containing three grains of iodide of potassium to the ounce, was ordered to be taken three times a day. The tumour was also freely painted with the iodine solution.

On Sept. 21, the note states, the voice is now almost clear, but when she speaks loud there is a slight laryngeal twang perceptible. The mixture was now substituted by one containing a drachm of the syrup of the iodide of iron.

On Nov. 30 she was discharged, the following being the note then taken:—"Has a perfectly clear voice, and can shout loud. The swelling of the thyroid is all but gone, and what remains is quite soft. She looks well, and expresses herself as feeling so."

## HOSPITAL NOTES.

### MODIFIED OPERATION FOR EPIPHORA.

After slitting up the lachrymal canals for the relief of epiphora, (the method introduced by Mr. Bowman, and now so generally adopted,) it now and then happens that only an incomplete result is obtained. Although a gutter for the tears of a quarter of an inch in length has been obtained, yet they do not wholly find their way into it, and the overflow still occurs during sudden increases of secretion. Mr. Critchett suggests that this is sometimes due to the two sides of the canal falling together too closely, and has proposed to remedy it by cutting the inner one wholly away. This is easily effected by means of a pair of small curved

scissors. A case now under care, the only one, we believe, in which the proposal has been carried out fully, confirms the expectations of benefit. The canal had been freely slit up some weeks before, and no union of its margin had followed, but still the tears occasionally ran over the cheek. The caruncle was large, and filled up the hollow which should naturally exist at the inner angle of the lids, and also somewhat tilted the lid outwards. Mr. Critchett cut away the inner wall of the canal, removing an elliptical piece of mucous membrane about a quarter of an inch long and an eighth broad in its middle. A little cup has now been formed in which the tears collect, and the apex of which is the nasal extremity of the canal itself. The liability to epiphora has as yet been wholly remedied. Mr. Critchett remarked the other day respecting these cases that he was convinced that an enlarged condition of the caruncle, pushing the lower lid with its punctum outwards, was not unfrequently a cause of epiphora, and suggested that the right practice might in such cases be to snip away part of that body, and thus draw the lid back into the proper position.

### DIFFICULT DETECTION OF CALCULUS.

Mr. Solly has at present a case of much interest under his care in St. Thomas's, in which very different opinions have been given as to the existence of a stone in the bladder. The patient, a man of 30, has three times been brought into the operating theatre, and sent back on account of those present not being able to satisfy themselves. Mr. Solly himself has, we believe, on each occasion entertained a confident opinion that he has struck the stone, but no sound perceptible to those standing by has been elicited, and in other hands the sound has forwarded no satisfactory evidence. It has been suggested that there is a calculus embedded in the prostate, or possibly encysted in the left side of the base of the bladder, in which positions the grating sensation has always been felt. In support of the diagnosis of an encysted stone is the fact that the man's sufferings are not severe. Some of our readers may possibly recollect a very instructive case recorded in our Hospital reports about five years ago, in which a man under Mr. Erichsen's care in University College Hospital died of abscess in the liver, having a large calculus encysted in the walls of his bladder. He had been under the care, first of Mr. Arnott, and latterly of Mr. Erichsen, for a long series of years, and the stone had repeatedly been felt. On several occasions lithotomy had been decided on, and the man placed on the table for its performance, but as no one had ever succeeded in detecting the stone at the time, it had always been deferred. The result proved the wisdom of the caution which had been exercised, for the stone was so almost completely encysted that its removal could not have been safely accomplished.

### DIAGNOSIS OF THROAT HÆMOPTYSIS.

The following notes on the characteristics of throat hæmoptysis as distinct from that attending pulmonary disease, are the memoranda of a conversation on the subject in the out-patient's room of the City Hospital for Chest Diseases. They may possibly interest some of our readers. When blood comes from the throat, *a*, it is always in very small quantity—*b*, it is never mixed with small air-bells—*c*, it generally occurs as streaks in mucus—*d*, almost always follows a fit of coughing—*e*, is of most frequent occurrence early in the morning—*f*, the patient often complains of having a dry throat on waking. When the hæmoptysis is spontaneous, or when it amounts in quantity to anything near a tablespoonful, it is almost always pulmonary.

### CANCER OF THE LUNG IN A CHILD.

An interesting example of extensive carcinoma of the lung, at the very unusual age of three years, is furnished by a little boy who now attends Mr. Hutchinson's out-patient room at the Metropolitan Free Hospital. The disease affects the upper and anterior parts of the right lung, and the dulness on percussion is complete, and extends over a large surface. The boy is emaciated, feverish, and very restless. No expectoration of blood has yet occurred. About the diagnosis there can be but little doubt, as Mr. Hutchinson excised the left testis nearly a year ago, on account of medullary cancer. The little fellow was then rapidly failing in health; but he quickly recovered from the operation, and became almost as robust as ever. The cord yet remains quite sound, and there is no evidence of the lumbar glands being affected. Cancer

is hereditary on his father's side. He furnishes a good illustration of the fact that growing cancers, especially when of considerable size, induce cachexia and wasting, quite independently of any pain caused, or of hæmorrhage, or discharges. Neither in the original or the recurred growth has there ever been any ulceration, nor has the boy suffered any material pain; yet in each instance he has rapidly emaciated during the growth of the tumour, whilst the degree of health regained after the excision of the primary one was most complete.

#### SUCCESSFUL EXCISIONS OF THE KNEE-JOINT.

The case under the care of Mr. Le Gros Clark, in St. Thomas's, to which we adverted some months ago, as being the most rapid recovery after excision of the knee which we had witnessed, affords now one of the most perfect triumphs of that operation which could be desired. It will be remembered that healing took place almost wholly by first intention, the outer wound being closed in about a fortnight. The woman now walks about with a firm straight limb, very little shorter than its fellow.—A boy, who is shortly to be discharged from the Metropolitan Free Hospital after excision of the joint by Mr. G. Borlase Childs, furnishes another instance of a most satisfactory result. His right knee had been disorganised by old disease, and the tibia dislocated outwards and backwards. In this condition he had been admitted about six months before the operation. A patient trial, both by forcible extension under chloroform after division of the hamstring tendons, and by gradual extension by means of a screw apparatus, had been made without success. Although not much swollen, the joint was still the seat of considerable aching pain, and the boy was thin and delicate. The fixity of the bones was such that Mr. Childs was obliged to saw through the shafts of the two bones from before backwards without having first separated them at the joint. This was done carefully and without any inconvenience, but extreme caution was necessary afterwards in dissecting away the united heads of the bones from their connexions in the popliteal space. A considerable collection of concrete material, the remains of a large abscess which had been absorbed, was opened in the front and inner part of the joint, but in all other parts the articular surfaces were most firmly united to each other. The boy had considerable constitutional disturbance for a week or more after the operation. Although the limb had been very firmly secured on a back splint, yet it was found about the tenth day that the femur had become tilted forwards, and had ulcerated through the anterior flap. To rectify this state of things, the boy was again put under chloroform, and the end of the projecting bone having been cut away with forceps, reduction was again effected. After this no trouble in securing good coaptation was encountered. Mr. Childs obtained great advantage from the use of a short splint in front of the femur. At present the boy is quite well, and about the ward. The limb is perfectly straight, and, though three inches shorter than its fellow, will be a very useful one. The wound, excepting a very small place, is soundly healed.

**THE PHYSICIANS' BILLS IN THE BURDELL MURDER CASE.**—The bills presented to the county of New York for medical and chemical services connected with the murder of Dr. Burdell, the dentist, were as follow:—Dr. Gouley, for microscopical examination of blood, etc., 300 dollars; Dr. Knight, for surgical examination of the wounds, inspection of clothing, dagger, etc., 350 dollars; Professors Doremus and Childs, for ten days' services in chemical and microscopical examinations, with chemical assistant, 400 dollars.

# Medical Times & Gazette.

SATURDAY, FEBRUARY 6.

## POSITION AND PROSPECTS OF MEDICAL REFORM.

PARLIAMENT has met again. Amid the important questions to be considered—the war against the Chinese empire—the past insurrection and future government of India—the safety of foreign refugees—the reform of our electoral system—and other matters of like magnitude, it is not probable that Medical reform can occupy much, if any, of the attention of either House. Still the business of a session of Parliament cannot be considered complete unless there be discussed a "Jew Bill," a "Salmon Bill," and a "Medical Bill." So said Sir Robert Peel regarding Salmon, so said Lord Elcho regarding Doctors. In truth, year after year these topics are floated along the surface of parliamentary proceedings—only to be swamped—to be raised and floated again, when the stream of parliamentary business is at its height, when little attention can be vouchsafed to the topics, or an unwilling hearing obtained for the forbidding subjects.

An "Oaths Bill" is acknowledged to be absolutely necessary for the relief of conscientious Jews, that they may breathe and swear with freedom in the atmosphere of the House of Commons.

Moreover, it is absolutely necessary that the Salmon tribe should be permitted to enjoy the full tenure of their existence in our seas and rivers—that they should be cherished, fostered, and protected while young Parrs, till they become mature and unwieldy salmon—that they may be encouraged to live as fish ought to live, in order that they may die the legitimate death of salmon. But, that these things may come to pass, it is necessary that the parrs and the salmon should have a Bill to regulate the tenure of their life and their mode of death.

Equally with conscientious Jews and deeply-injured Salmon, those who practise the healing art within the realms of the British empire, require legislative interference on their behalf. The numerous attempts that have been made during the past fifty years to legislate on Medical Reform, have demonstrated how much need there is for some measure which will "alter and amend the laws" by which the Medical Profession shall be governed. They have shown also how serious is the undertaking, and how powerful must that effort be which shall reduce the chaotic mass of our Profession into a uniform whole.

The condition of Medical affairs becomes more and more serious every day; and the longer an efficient measure of Medical Reform is withheld from us, the legislative enactments which advance and promote the general sanitary interests of the community leave the confusion of interests of the Medical Profession more and more confounded. Any one who has given the least attention to Medical affairs in Parliament during recent years—who has observed the progress of discussion, not only on the various Medical Bills which have been introduced, but also on those topics bearing on the practice of Medicine in Workhouses, Asylums, Hospitals, and the promotion of Sanitary science generally, cannot but see how recent enactments tend to multiply the divisions of our Profession, and widen the breaches between its sections. When laws are made to regulate and amend the mode of existence of national or civic institutions, we, as a Profession, are left behind. We are left behind, because no one knows how we may be safely interfered with; and therefore we are

rather let alone, because it is found impracticable to arrange the conflicting interests of our sections. Many new enactments have been made, especially since the accession of our present gracious Queen to the throne of these realms, influencing indirectly the position of Medical men in relation to each other, and to the public generally.

In 1848 the "Public Health Act" was passed, and now continues to drag out a most incongruous existence, so far as its relation with the Profession of Medicine and the institutions of the Profession are concerned. "Nuisance Removal Acts" and "Boards of Health Acts" have had to be confirmed. Special Acts, relative to Medical attendance on the poor, the care and inspection of emigrants and emigrant vessels, of lunatic asylums, and Acts respecting legal and efficient vaccination have been severally enacted at various times, and all of them fully demonstrate the pitiable position and discordant state in which the members of our Profession exist. Nay, it has even been necessary that special clauses should be introduced into special Bills, in order that the word "Medical" shall be construed to extend to and include the term "Surgical."

The tide of popular opinion has long set against the continued existence of corporate monopolies, and although it has continued hitherto to sweep in whirling eddies past the huge unwieldy masses of the Medical Corporations, yet the undercurrent is rapidly undermining their foundations, and in the end great must be the fall thereof. Already, in England, Scotland, and Ireland, many of the ancient rights and privileges exercised by these bodies have been obliged tacitly to be relinquished under the influence of this popular feeling.

The cause of this unsatisfactory state of things is, doubtless, to be traced in the absence of all uniform organisation of the Medical Profession. Unlike the Law and the Church, *We*, as a Profession, recognise no head—no representative. Medical men have rarely been able to secure a seat in the House of Commons, and when they have done so they can scarcely be considered as even "representatives." When they do find a seat in Parliament they take their places in the House of Commons as representatives of civic communities, not of a learned, enlightened, and humanising profession. Moreover, before they gain such an honour, and the confidence of a constituency, they have generally ceased to be acting members of our Profession;—they have become active citizens, caring anxiously for the political and municipal interests of the people, having ceased altogether from medical attendance on the sick. While "a complete body of Divinity" luxuriates in the Upper House; while the profession of Law has its Attorney-General in England, and its Lord-Advocate for Scotland, each of them able to secure a seat in Parliament, our Profession, second only to one in the sacredness of its mission, in the greatness and nobleness of its nature and of its aims, has no Physician-General to interest himself in its welfare—to watch over its concerns—to protect its rights, to aid in the maintenance of its position amongst the community, and the advance of its science. Hence also it is that questions which involve an accurate and an extensive knowledge of the science of medicine do not receive that unbiased, that matured consideration and elaborate discussion which they demand;—that questions which affect the interests of public health are virtually determined by men who have no voice in Parliament, but whose professional opinions must be obtained and instilled into those who are to settle the most abstruse questions in State Medicine. It was only by the determined exertions of an eminent and active member of our body that a Medical Officer of Health was permanently attached to the Board of Health; and although we may not live to see the day, still we hope that the Medical Profession may yet be represented in Parliament as

it ought to be. We wish to see some distinguished Physician the President of the Board of Health, (not in the subordinate position of its Medical officer), but with a seat in the Privy Council of Her Majesty's Government, and a voice at least in the Legislative Assembly of our country.

The want of unanimity, general supervision, and organization of the Profession is stamped upon every Act which professes to regulate the practice of medicine in our land. Accordingly the Charters and Acts of Parliament relating to the practice of Medicine and medical affairs generally from the time of Henry VIII. may be characterised as a most conflicting mass of legislative enactments, demonstrating this lamentable want of unity and unanimity of supervision in the management and control of our affairs. Nay, more, the acts which exist and which profess to regulate the practice of our Profession, are impressed with internal evidence of their origin—an origin of which we have no reason to be proud. The individual rights and legal charters of one body appear to have been secured by stolen marches upon the others. Thus these bodies severally became secured in complete monopolies over limited jurisdictions, and the acts are records of exclusive and peculiar privileges granted to each of them. Institutions whose privileges have thus been secured by private intrigue, perpetuated and rendered more exclusive by similar means during the past three hundred years are necessarily narrow in their scope of usefulness, illiberal in their aims, exclusive in their rights and privileges, and limited in the local range of their lawful jurisdiction. Opposing each other in what ought to be the common interest of all, they are prejudicial to the well-being of the public at large; and, while they foster and tacitly encourage trading monopolies, they are obstructive to the advance of the science of Medicine concurrently with the advance of other sciences, and their continued existence *in statu quo* is incompatible with the spirit of the age. As the country advances in the knowledge of those circumstances which contribute to promote her national health, enterprise, and wealth, the science of Medicine is from time to time required to lend its aid in the promotion of social improvement, but the means to effect this end become at once conflicting when the interests of Medical Corporations are threatened to be assailed.

The Acts which established Universities in this country,—the most ancient seats of learning which now exist,—are impressed with the spirit if not the letter of the law, that those taught within the walls of these venerable institutions should go forth competent to preach, to teach, or to practise whatever had been taught them in the sciences of Divinity, Law, or Medicine. But Corporations, like mushrooms, quietly and insidiously sprung up around them, and the Medical corporations, like the mediæval guilds of Goldsmiths, Silversmiths, Cordwainers, Shoemakers, by stolen marches upon these ancient and noble seats of learning, as well as upon each other, have all but neutralized their power and privileges, and confounded the interests of all.

Thus it is that the Medical profession is divided into opposing sections, containing the elements of discord and contention. No one, therefore, can be surprised at the agitation which shakes and undermines the foundations of our Medical institutions, when we are regulated by no national legislation like the Law and Religion of our country, which commands the respect of nations. When the rights and privileges of sections of the Profession assume new aspects, from the advance of other institutions under the fostering care of a liberal government, the Medical Profession finds itself left behind, with its rights and privileges becoming more and more numerous, incongruous and conflicting.

The time has certainly arrived when the 19,000 Medical men of this country must assert their position in the land,

and endeavour to obtain from Parliament a clearly defined "locus standi," in spite of the conflict between the contending interests of Medical Corporations and Universities. It having happened almost every parliamentary session during the last fifty years, that measures "to regulate and amend the laws which regulate the Medical profession," have been thrown out by the influence of the contending interests of these bodies, it is not unlikely that the same fate awaits the measures to be discussed in the present Parliament. If such an event happen, let us, as a body, petition Parliament for a ROYAL COMMISSION, to inquire into our position, whose decisions, and recommendation to the Home-Secretary, shall be final. While we were the first to recommend this step, in our Number for July 11th, 1857, let us now earnestly and strenuously impress upon our Professional brethren the power and importance of this mode of settling the question. Let such a Commission be empowered to hear evidence and obtain documents bearing directly or indirectly upon the whole subject of "Medical Reform." Let it be empowered, with the aid of competent legal men, to examine into the state of our Medical Corporations and Universities. Let the Commission be empowered to ascertain minutely the revenues of all of them, the sources of these revenues, and how they are disposed of. Let it ascertain and determine the relation of the several Corporations to the members of the Profession generally. Let it appreciate and put before the public, the benefits (if any) which the Profession as a body and which the Public derive from the continued existence in their present state of the exclusive Medical Corporations. Let it inquire into the education and examination of Medical men by the Universities, corporate licensing bodies, and schools of Medicine. Let it examine into the varieties of the licences to practise, and the privileges conferred upon Medical men by corporate bodies and Universities.

Without information, such only as a "Royal Commission" so empowered can collect, there never can be obtained any just and reasonable ground of adjudication between the conflicting interests of Universities, Corporations, the members of the Medical Profession as a body, and the public generally.

By this means the 19,000 members of the Profession will aid in assigning to these corporations the position they ought to hold among the Medical institutions of the country, and the position of the Universities. We, as a Profession, may then feel that we have effected an efficient and satisfactory reform, in place of these contending institutions being permitted to compromise the position of those who constitute the great mass and strength of our professional ranks.

In the meanwhile, we shall endeavour to lay before our readers, from time to time:—

1. A short historical account of the measures proposed in recent years to secure an Act of Parliament to "alter and amend the laws regulating the Medical Profession," the origin of those measures, the motives which influenced their progress and frustrated the endeavours of their promoters.

2. An account of the position of contending parties in and out of Parliament who advanced or opposed the special measures before Parliament at the close of last session.

3. An analysis of the measures before the House of Commons, and the circumstances which may not only tend to prevent agreement, but which may lead to unsatisfactory compromise, and perhaps to the absolute frustration of the adoption of any measure.

4. In the event of this not at all improbable result, we shall endeavour strenuously to urge the necessity of finally settling the question of Medical Reform through the medium of a *Royal Commission*.

## THE WEEK.

On the 31st instant, a committee of gentlemen, headed by Sir John Forbes, Dr. Andrew Clark, Dr. Brown, and others, waited upon Dr. M'William, on behalf of the Medical officers of the Royal Navy, for the purpose of presenting him with a magnificent service of plate, as a token of respect for his distinguished character and services, and as an expression of gratitude for his long, disinterested, and finally successful advocacy of the claims of Assistant-Surgeons to ward-room rank. In detailing the circumstances which had more immediately led to this presentation, Sir John Forbes made an eloquent speech, which will be found in full in another column, together with Dr. M'William's reply. Sir John formally presented the testimonial, which consisted of a splendid salver, with a dinner and tea service, of richly-chased silver. Long may Dr. M'William live to enjoy his well-earned honours!

Sir Colin Campbell's last despatch contains the following gratifying passage:—"I must not allow this opportunity to pass without bearing my testimony to the unwearied zeal and assiduity of the Superintending Surgeon, Dr. J. C. Brown, Bengal Artillery, which have never flagged for an instant, and have been of the greatest use to the force in the field from the time the troops first took the field before going to Delhi. I beg to recommend him most particularly to your Lordship's favourable consideration."

Mr. Pocock, of Brixton, has obtained £250 damages against an attorney named Nicholls, for an assault and defamation of character. The action was tried before Lord Campbell on Tuesday. The attorney had charged the Surgeon with having committed adultery with Mrs. Nicholls. There was not the slightest ground for any such accusation, and Lord Campbell well observed, "There did not seem to be the slightest cause of suspicion with regard to Mr. Pocock, and yet the most serious and frightful charge had been made against him. For a Medical man who was called in to attend a lady in her confinement to abuse the confidence placed in him, and to seduce her, was so atrocious a crime that the imputation of it would work the utter ruin of the person to whom it applied. The plaintiff was entitled to recover damages upon both counts, and he was bound to say that Mr. Pocock would leave the court without the slightest stain upon his character. It seemed to be a most groundless charge against a respectable and honourable man, and the jury would give such damages as would show they concurred in that opinion." If sitting on a sofa with a lady and feeling her pulse are acts to be construed by a jealous husband into adulterous criminality, what Medical man could exercise his Profession in safety?

The doings of the American horse-tamer, which have been detailed so fully in the daily papers, have excited considerable attention among scientific men. The nature of the power exercised by this man, and the manner in which he is enabled to reduce the most unruly animals to obedience, is a very curious physiological problem. On Monday, among several visitors at the riding-school at Buckingham-palace before whom experiments were made, there were Sir James Clark, Sir Henry Holland, Dr. Lyon Playfair, and Mr. Spencer Wells. The American was shut up in a loose box with a very spirited stallion, four years old, which he had never seen before. When the visitors were admitted, he was lying on the straw beside the horse, who allowed him to knock his hoofs together, and did not oppose his force in any way to the will of his master. Lord Alfred Paget, who had learned the secret, also exhibited similar power over a pony.

Other gentlemen have been entrusted with the secret, and it appears, from what they say, that there is nothing cruel or objectionable in the plan followed, but that it is the first step in a system of education. The horse is first taught to be submissive, and if kindly treated he is said to continue docile. The American professes to continue his system until the horse will obey the voice like a dog. How such rapid submission is obtained is the secret. It has been imagined that, like the "Whisperer," whose secret died with him, something is done by breathing into the nostrils. Others have tried this, however, and failed. Whatever the secret may be, it is one certainly worth knowing, and we shall be glad to hear that the five thousand pounds required before it can be made known is subscribed.

The Clerk of the Coroners of Liverpool has just prepared a statistical return of Inquests held before the Borough Coroner during the year 1857, from which it appears that "few inquests take place on any member of a family above the labouring classes: if an accident happen in a wealthy family, the family-surgeon is sent for, and if no crime has been committed, he gives a certificate, and the family are spared the annoyance of a Coroner's Inquest!" Thus saith the report: but how many cases of sudden or unexplained death may happen not necessarily involving an implication of murder, which nevertheless require investigation, and which it is absolutely culpable in the parties who are cognisant of the matter, to hush up? Further, the Liverpool return says, "453 cases of deaths reported to the Coroner's Court by the police and others, into which the Beadle made inquiries, and inquests were not considered necessary, thereby saving an expense of upwards of £960!" How the Beadle could be considered a competent judge or witness as to the cause of death it is difficult to say. The saving of expense seems to be the all-important object in these proceedings. It is not confined to one town or one city; it is a general, a prevailing evil; and it cannot be doubted by those who have an opportunity of studying the question in more aspects than one, that if these public investigations were to take place more frequently, cases to require them would soon become more rare. Thus, instead of an increased expenditure, which is so much feared, a saving of expense would be the result. Nothing is a greater drag upon the financial resources of a county or a parish, than the constantly recurring cases of sickness and death amongst the poor. If they and others are beyond or below the power of moral influences, legal restrictions and inflictions must be brought to bear upon them; and the subject that has now been under consideration must necessarily claim a prominent degree of attention should any measure referring to Medical jurisprudence come under the notice of the Legislature in the next session of Parliament.

We have lately published some extracts from letters appearing in the *Morning Post*, under the signature "A Physician," written in a very bad spirit; the author attempting to show that the professional ardour and benevolent exertions of young medical men in the cause of charity are all based upon the lowest form of selfishness. He has made a special onslaught on special hospitals and their founders. Here he has been answered by Dr. Savage, who, after showing the advance made in Ophthalmic Surgery since the establishment of Eye Hospitals, thus replies to the author's objection to special hospitals:—"It has been objected to special hospitals that they absorb subscriptions rightfully belonging to general hospitals. In reply to this I will contrast the origin of two hospitals. The enormous sum of £30,000 was spent on the bare walls of St.

Mary's before a single patient was relieved. Fifteen beds were put into a private house in Orchard-street, and the Samaritan Hospital for women was in working order then and there at the cost of £100. Every surgical operation of importance has been performed there, and the average number of out-patients is 130 per diem. Let the claims of such institutions only be measured by the amount of benefit they confer at the same cost, and a glance at the history of special hospitals must decide the unprejudiced in their favour, if distinction must needs be drawn where both kinds are so urgently wanted. \* \* \* Free, cheap, ready, and efficient relief at those places is the rule, the correspondent of the *Morning Post* notwithstanding; and it is here, regardless of the sacrifice of time and energy, that the aspirant may be daily seen doing an amount of real good which no other class has ever shown itself willing or able to effect. What if he thus endeavour to qualify himself for what is called high-class practice, which, at the best, is but another name for hard work, and even so seldom reached before the age when every other pursuit is rewarded with retirement and decent competence, at a tenth part of his self-denial and exertion?"

Let our readers consider well the concluding paragraph in the last quarterly return of the Registrar-General. It is here for their perusal:—

"England is a great country, and has done great deeds. It has encountered in succession, and at times in combination, all the great powers of Europe; has founded vast colonies in America; and has conquered an empire in Asia. Yet greater victories have to be achieved at home. Within the shores of these islands the twenty-eight millions of people dwell who have not only supplied her armies, and set her fleets in motion, but have manufactured innumerable products, and are employed in the investigation of scientific truths, and the creation of works of inestimable value to the human race. These people do not live out half their days; a hundred and forty thousand of them die every year unnatural deaths; two hundred and eighty thousand are constantly suffering from actual diseases which do not prevail in healthy places; their strength is impaired in a thousand ways: their affections and intellects are disturbed, deranged, and diminished by the same agencies. Who will deliver the nation from these terrible enemies? Who will confer on the inhabitants of the United Kingdom the blessings of health and long life? Who will give scope to the improvement of the English race, so that all its fine qualities may be developed to their full extent under favourable circumstances? His conquests would be wrought neither by wrong nor human slaughter, but by the application of the powers of nature to the improvement of mankind."

## REVIEWS.

*Untersuchungen ueber die Entwicklung der Blutgefasse.* Von Dr. TH. BILLROTH. Pp. 81. Berlin: 1857.

*Researches on the Development of the Blood-vessels.* By Dr. TH. BILLROTH.

Dr. Billroth, Lecturer on Microscopic Anatomy at, and Assistant-Surgeon to, the University College Hospital at Berlin, has given special study to the important matter of the development of the blood-vessels, both in the physiological and pathological states, and recorded in the above work his microscopic observations on the development of the blood-vessels in the area vasculosa of the fowl's egg during incubation, in the tail of the frog-larvæ, in the foetal cellular tissue, in granulations and cicatrices, and, finally, in certain tumours.

According to Dr. Billroth's observations, there are three different kinds of development of the blood-vessels:—1. Round cells lying close to one another unite; the contents of the cells is changed to blood-corpuscles, which come into circulation by rupture of the cell-membranes, the walls of the vessels being only formed by the cell-membranes themselves.

2. The cells elongate, assume a spindle-shaped appearance, and leave a canal between them. 3. Offshoots arise from the walls of the vessels, become hollow, and finally form canals, which come into connexion with the canals of the primary blood-vessels.

The observations of Dr. Billroth on the process of granulation and cicatrization are summed up as follows:—If there have been any extensive wound, a part of the wounded tissues is always removed by necrosis. Then exudation sets in from the capillary vessels on the surface of the wound. The tissue itself is dissolved with the exudate to a homogeneous substance, within which begins the formation of cells. Capillary vessels are formed out of the cells, and from these new vessels fresh exudation arises. Before the epidermis has been re-formed the tissue is condensed by resorption of the intercellular substance; most of the vessels are obliterated, and remain in the cicatrix as solid cellular tissue. This process begins earlier in the deep layers of granulations than in the superficial ones. The contractile power of the cicatrix is caused by the resorption of the intercellular substance, and by the obliteration of the blood-vessels. Dr. Billroth never found any follicles, papillæ, and nerves, in the cicatrix, but always bundles of cellular tissue and elastic fibres. The formation of the cicatrix is seldom completed until a whole year has elapsed after the infliction of the wound.

Finally Dr. Billroth relates his observations on certain tumours not yet described microscopically. The "collonema" consists entirely of a mass originally gelatinous, not closed by a cyst, and not arising from mollification of formerly solid masses. A tumour of this kind, as large as a fowl's egg, was observed by Dr. Billroth on the external opening of the inguinal canal of a boy; it was removed by the knife, and did not return. The "tumour glomerulosus" consists almost entirely of blood-vessels, and is much like the alveolar cancer. The "cylindroma"—instances of which have also been observed by Professor Busch at Bonn, and by Dr. A. de Graefe at Berlin—is a tumour arising from the lachrymal gland, which is first hypertrophied, and afterwards destroyed by rapidly growing cylinders of cells.

Dr. Billroth has also examined microscopically a large number of teleangiectasies, and has come to the conclusion that these tumours are composed of newly formed vessels having a much larger diameter than the capillary vessels of the skin. The growth of these vessels arises chiefly from the capillary nets of the glands of the skin, of the roots of the hair, and of the papillæ.

Five engravings drawn up from the microscopic preparations of Dr. Billroth, have been very well executed, and add to the value of this work, which merits a place in the library of those who take a special interest in microscopic anatomy.

*The Physiology and Treatment of Placenta Prævia; being the Lettomian Lectures on Midwifery for 1857.* By ROBERT BARNES, M.D. Pp. 208. London: 1858.

THESE Lectures were delivered last year before the Medical Society of London, and they have also appeared in the pages of a contemporary. Dr. Barnes gives a very philosophical view of the nature of Placenta Prævia; and while he repudiates any attempt to establish dogmatically a new method of treatment, he calls in question the propriety of employing empirically the remedial measures now generally practised. Dr. Barnes's treatment of the affection is eclectic, each case being treated according to the peculiar features it may present.

*On the Transmission, from Parent to Offspring, of some forms of Disease, and of Morbid Taints and Tendencies.* By JAMES WHITEHEAD, M.D. F.R.C.S. M.R.I.A. Second edition. Pp. 432. London: 1857.

THE demand for a second edition of this work proves the interest which the subject has excited among the members of the Medical Profession; and the author has taken the opportunity of furnishing many additional facts in corroboration of the views which he originally advanced in relation to the transmission of syphilis from parent to offspring. Although Dr. Whitehead offers some general remarks upon the hereditary character of other diseases, it is to the communicability of syphilis, and the treatment of this affection, that his pages are chiefly devoted. Apart from its great merits as a scientific treatise, Dr. Whitehead's volume tends to promote very powerfully the

cause of morality, by showing the physical misery entailed very frequently upon helpless and innocent beings in consequence of venereal delinquencies.

*A Sketch of the Principles and Practice of Subcutaneous Surgery: being the Oration delivered before the Medical Society of London, at their Eighty-fourth Anniversary, March 9, 1857.* By WILLIAM ADAMS, F.R.C.S., Surgeon to the Royal Orthopaedic Hospital. Published at the request of the Society. Pp. 67. London: 1857.

IN this Oration Mr. Adams brings together with great ability a number of facts and reasonings, to prove the many advantages attendant upon the performance of surgical operations in parts which are not exposed to the influence of the air. As illustrations of this subcutaneous surgery, he adduces the successful results of tenotomy, the operation for strabismus by dividing the muscles of the eyeball, that of Wutzer for the radical cure of reducible hernia, subcutaneous operations for the cure of varicose veins, and other proceedings of a like kind in other regions. The danger of compound fractures, on the other hand, is greater than that of simple ones, because in the former there is an external wound; and the unfavourable results of trephining are attributable to the irritation and suppuration caused by the exposure to the atmosphere. Mr. Adams's Oration will well repay perusal: it is the production of one who has made himself acquainted with the literature of his subject, and has mastered its practical details.

*On the Study of Epidemic Disease, as illustrated by the Pestilences of London; being a paper read before the Epidemiological Society of London at the opening of the Session 1857-58.* By E. HEADLAM GREENHOW, M.D. London: 1858.

THE author of this paper displays great powers of research in describing the different pestilences which, in the form of black death, plague, sweating sickness, cholera, and influenza, have at different periods visited this metropolis. With regard to the causes, prevention, and treatment, of these dreadful visitations, Dr. Greenhow does not give any information, nor does he give any opinion as to their mode of propagation. He inclines to the belief that, although malignant epidemics may be introduced from one country to another by the medium of ships, yet a certain constitutional predisposition must exist among communities, to enable the germs of disease to exert their morbid power. The influence of meteorological phenomena in connexion with the outbreaks of epidemics is briefly noticed; and the paper contains much information and much suggestive material in a very small space.

*A Manual of Qualitative Analysis.* By ROBERT GALLOWAY, F.C.S. Second Edition. Pp. 197. London: 1858.

WE are happy to announce a second edition of this very useful little work, which is well calculated to assist the chemical student in practical analysis. The directions given are so plain as to be intelligible to any common understanding; and the tyro in chemistry, with this book in his hand, and a few necessary implements, will be soon able to comprehend all the fundamental principles of that science.

*Mind and Body: a Discourse on the Physiology of the Phrenical action of the Cerebrum.* By ROBERT JAMIESON, M.D. Aberdeen: 1858.

IN this very brief discourse, a sketch is drawn of the powers and faculties of the human mind, and their connexion with, and dependence upon the bodily organs. This very difficult subject is treated by Dr. Jamieson with great perspicuity, being entirely free from that mysticism which too often prevails in physico-metaphysical speculations.

**PRIZE QUESTION.**—The Société des Sciences Médicales et Naturelles de Bruxelles offer a prize medal, value 300 francs, for the best essay on the following subject:—"Indicate the physiological and pathological facts discovered by aid of the ophthalmoscope. Which are the diseases of the eye in which its employment may prove of utility?" The memoirs, written in French, Latin, German, or English, to be forwarded, post-free, by the 1st July, 1858, to the Secretary, Dr. Van der Corput, Rue d'Arenberg, No. 14.

## PROGRESS OF MEDICAL SCIENCE.

## Selections from Foreign Journals.

## ON SCORBUS AS OBSERVED IN THE FRENCH ARMY IN THE CRIMEA.

By M. PERRIN.

Endemic scorbutus has hitherto appeared under such special conditions, as to assume from these a too great exclusiveness of character, which it is of importance to free it from before its general history can be written. It is only as contributing to this object that M. Perrin presents this sketch of the physiology of the epidemic he had the opportunity of witnessing. It has been long the habit to regard scorbutus as a disease peculiar to seamen and long voyages, scorbutus as it occurs among landsmen being scarcely acknowledged. One of the objects the author has in view is to show that this disease is not dependent upon any specific cause or peculiar to a maritime life; and that it is but the manifestation of morbid conditions generated within the economy by the disordered action of the hygienic modifying circumstances upon which life and health depend. If epidemics of scorbutus are of more frequent occurrence aboard ship, it is because there are to be most frequently found united the causes capable of producing it. This idea is in nowise novel, for it is to be met with in every page of the works of Lind, Boerhaave, and Van Swieten; but it seems not sufficiently acknowledged in special works and modern classics.

*Etiology.*—M. Perrin passes in brief review the various hygienic circumstances the French soldier was subjected to. The supply of fresh meat was only defective at first, when scorbutus did not prevail in the camp. From February 1855 it was distributed at first twice, and then five times a week. It was of good quality except that it was very lean. The supply of bread was not always regular, and rice was the most constant means of making up the amount of the soldier's rations. The absence of fresh vegetables and fruits was felt as a most severe privation, the preserved vegetables forming a most insufficient substitute. To this deficiency the author greatly attributes the outbreak. In other respects the regimen, after the first four months, was very tolerable. But the uniformity and incompleteness of the diet soon wearied the stomach, and brought about chronic diarrhoea, which led to progressive wasting of strength.

In respect to one or two articles of diet M. Perrin makes some interesting remarks. *Coffee*, he thinks, has enjoyed in the French army a somewhat exaggerated reputation since its employment during the Algerian wars. In the Crimea he found that the officers who took coffee fasting often suffered from a fatiguing excitement, irritation of the skin, sweating, vertigo, a fulness of the stomach interfering with their breakfasting, or vague colicky pains followed by serous stools. In several messes these inconveniences ceased on substituting tea. The common soldier suffered less, not only because his nervous system is less impressionable, but because he prepared his coffee not by infusion but by prolonged ebullition, forming with biscuit a kind of panada. Nevertheless, in many instances, it was observed that coffee taken regularly on quitting the trenches, so far from supporting the soldier's strength, gave rise to mere excitement, soon to be followed by exhaustion and a kind of syncope. *Brandy* also was frequently mischievous in its effects. Intended to be mixed with the coffee, or with the water in order to correct the bad qualities of the latter, it was almost always taken neat, either while in the trenches or on the return from them. Thus taken it stupefied the enfeebled economy, and the roads from the trenches to the camps were strewn with soldiers who were rather surprised than intemperate.

Added to the too uniform alimentation, was a no less powerful cause, viz. humidity, the efficiency of which has been acknowledged by most authors. During the whole of the winter of 1855, the soldiers had to march a long distance up to the knees in snow or mud, to reach the trenches, to pass usually twenty-four, and sometimes twelve hours, in these when filled with ice-cold water, having on their return to camp no means of drying their clothes, and frequently not of changing them. What contrivance in clothing could provide against this horrible wet penetrating through all, and

dissolving everything! Even in the fine period of the year the nocturnal humidity was excessive. Thus the army was placed in a very exceptional state as regards wet, and one highly favourable for the development of endemic scorbutus. It is, moreover, worthy of remark, that this exposure to cold wet seems to have imparted a peculiarity to the disease; for the lower extremities, which were especially exposed to its depressing influence, were the principal place of election of the scorbutic manifestations. Lastly, we may note as not without its importance, the excessive fatigues and the moral condition of an army engaged in a contest for eleven months without truce or repose.

From what has been said, it results that the scorbutus of the Crimean army depended upon three causes, mutually aiding each other: an alimentation incomplete in itself, and taken at irregular intervals, and excessive nervous expenditure enfeebling the functions of the stomach. These two causes together induced indigestion, with diarrhoea or vomiting, whence arose complete prostration and wasting of the powers, taking on the scorbutic form, under the influence of permanent humidity.

*Symptoms.*—After a certain period of stay in the Crimea, the troops almost invariably contracted a diarrhoea, which it became impossible to free them of. Fever being always absent, three or four stools were passed daily, with little or no pain, but accompanied by extreme prostration, and such a tendency to syncope, that the slightest movement, a ray of sun, or a moment's exposure to the heated atmosphere of the tents, produced sudden paleness of the face, decoloration of the mucous membranes of the mouth and eye, cold sweating, and frequently fainting. The stools were viscous, very fetid, dark in colour, frequently streaked with blood, and almost always mixed with white lumps of concreted mucosities. The number seldom increased, nor was there tenesmus. This valetudinarian state exhibited an unexampled tenacity; and during several months half the army suffered from its depressing influence. But, while it proved refractory to all treatment, it was rare to find it increasing in gravity, so as to endanger of itself the life of the patient. This camp diarrhoea, long since described under various names, has never, as far as the author knows, been before observed upon so large a scale, exhibiting such relative benignity with such a placid tenacity. Is it, in fact, a distinct disease? or should it be regarded as one of the forms of the scorbutic state? The intensity of the general phenomena, the presence of blood in the stools, and the persistence of the symptoms, seem to favour the latter opinion.

However this may be, the numerous cases of confirmed scorbutus observed always took their rise in this valetudinarian condition. Pains in the lower limbs, and especially in the knees, invincible horror of all motion, engorgement of the knees and calves, some puffiness and a greenish pallor of the face, together with difficulty of respiration, were usually the assemblage of symptoms that ushered in the affection. Contrary to what is observed in most general affections, morning, between the hours of nine and ten, was the period of exacerbation. The affection might remain for a long period stationary at this stage; but in the great majority of cases spots of the skin rapidly supervened, these being always preceded by the specific pains. They varied in extent and colour, and corresponded well in their appearances to the descriptions given by authors. When seated on the ankle, and radiating towards the calf, this last became the subject of a special induration of the cellular tissue, which can only be compared to scleroma, the subjacent mass being as hard as wood, and not yielding to pressure as in oedema. The slightest pressure or movement induced the most acute pain. The local heat of the part was sensibly increased.

During the course of this morbid evolution, the scorbutic state of the gums was, exceptionally only however, observed; notwithstanding that it has been set down too often that the gums are almost constantly the seat of the earliest manifestation of scorbutus. In fact, however, the disease may exist without its ordinarily reputed symptoms. Those which were never absent were a feeling of utter exhaustion, horror of all movement, piercing pains in the lower limbs, and a difficulty of respiration not justified by the condition of the chest. In more than 600 scorbutic patients these symptoms, in different degrees, have never been wanting. The diarrhoea, or benign dysentery, already spoken of, generally accompanied the scorbutus, constipation being only exceptionally present. The

pulse was small, frequently irregular, but very rarely febrile; the skin was dry and parchment-like, the urine spare and sedimentary, and the cerebral functions were always unimpaired.

*Accidents.*—Among these, *contraction of the tendons* was a rather frequent consequence of the painful muscular engorgement already described. Its exclusive seat was the posterior region of the thigh, the muscles of which retained the leg in a semiflexed position, uninfluenced by any traction employed. It was remarkable that such contraction never affected the tendo-Achillis, producing forced extension of the foot, notwithstanding the painful condition of the muscles of the calf. The contraction was purely convulsive, so that after every effort had been used in vain to straighten the semiflexed leg, this was accomplished with ease on the employment of chloroform. These contractions persisted as long as the disease, and in the end led to articular swelling, like that which results from keeping a limb too long unmoved.

Another consecutive accident was of rarer occurrence, but of more serious consequence, viz. *difficult respiration*. This has already, indeed, been mentioned as a constant symptom of scorbutus; but it sometimes assumed the form of such a serious complication as to constitute one of the most dangerous accidents of the disease. The scorbutic patients of the Crimean army were rapidly transported to Constantinople before the disease could compromise their lives. One circumstance alone defied all precautions, viz. the sudden outbreak of an affection of the chest, which proved promptly fatal. In a single night three scorbutic patients of the author's regiment died in this manner, and in a few days he himself nearly underwent the same fate. The invasion of this symptom was quite sudden. To the ordinary difficulty of breaking of the disease, there succeeded, generally in the course of one night, the extreme anxiety and an almost absolute impossibility of breathing. The thorax seemed as if compressed by an iron hoop, while the severest pains traversed the base of the chest in every direction, and compelled an immovability which only yielded to imminent asphyxia. No one can picture the anguish of an unfortunate patient thus surprised, who amidst comparative health, without fever or any cerebral reaction, finds himself suddenly condemned to absolute immovability, either in the standing or sitting position, scarcely able to articulate a syllable, and obtaining a little air only at the expense of the most violent muscular efforts. In contrast with this the pulse is small, but irregular; the heart beats feebly; the respiratory murmur, though more indistinct, is unaccompanied by *râle*; percussion detects no effusion or notable congestion; and the skin, though dry, is devoid of febrile heat.

Once produced, this accident persists until death or change of place, manifesting regular alternations of better and worse, according to the hygienic conditions by which the patient is surrounded. The appearance of this complication is not peculiar to any special stage of the scorbutus, and it sometimes even precedes all organic manifestations of the disease. M. Perrin believes that the thoracic pains spoken of by Lind and Boerhaave are of the same nature as these here described; but he has never found them, as described by Lind, confined to one side, or modifying the piercing pains of the limbs. He is disposed to attribute their production to contraction of the diaphragm, all the muscles of relation being liable to become scorbutic, i.e. to acquire the painful engorgement so commonly seen in the muscles of the thigh and calf. In such a condition a muscle cannot contract, or impart the slightest movement, but at the expense of the most vivid pain; and if we supposed the diaphragm so affected, we should have a ready explanation of the excessive difficulty of breathing, unconnected with pulmonary lesion and of the relief derived from bringing into play the great thoracic inspiratory muscles.

*Treatment.*—Anti-scorbutics, quinine, bitters, aided by tonic regimen and the different acids, all were found uniformly of no avail, and nothing that could be devised could be substituted for change of locality, which was the great remedy. The author admits he had no opportunity of trying the efficacy of lemon-juice on a large scale. (May we not attribute to some extent the complete absence of the disease in our own army to the ample supply of this valuable substance it was furnished with?)—*Union Méd.* 1857, Nos. 103, 104.

### IMPERFORATE RECTUM.

On the occasion of the relation at the Boston Medical Society of some cases in which the operation had been performed without success, the following opinions were delivered:—Dr. Bigelow remarked that, judging from results, he did not think the operation for imperforate rectum, or even for imperforate anus, a desirable one. In the former case, the blind extremity of the upper portion of the intestine is often high up, and it would be practically impossible to maintain any communication with it after operation, except by a fistulous track through cellular tissue having a tendency to contract, to inflame, and to become obliterated, like other fistulous openings. This might occur in a favourable case; but in the majority of cases in which he had operated he had failed to find the upper gut, even when distended. This result must not unfrequently occur: the peritoneum is often perforated, and neighbouring organs are injured. Indeed, the region is so deep, and the canal is so narrow, barely admitting the little finger, that manipulation is attended with much uncertainty, which should be considered, as well as the very unpromising character of the result. Dr. Bigelow had never seen a successful case. As to *imperforate anus*, he could only speak of one case, in which the tendency to contraction after dilatation was such as to render the life of the little child miserable. Defecation was always attended with pain, and the constant use of the bougie, and repeated scarification were necessary. He believed that in the present state of art, it is better that a child born with either of these imperfections should die without this operation, although it must occasionally be performed in deference to established opinion.

Dr. Jackson spoke of the liability to error on the part of the surgeon in operating, and the slight chance of ultimate success of the operation under the most favourable circumstances. In one case the rectum was transfixed, the instrument passing through its wall into the peritoneal cavity. In another, the instrument passed up by the side of the rectum without penetrating it. In a third a free opening was made into the vagina. He mentioned still a fourth, where the instrument did not enter the rectum, and probably passed into the cavity of the peritoneum. With regard to the comparative frequency of cases of imperforate rectum and imperforate anus, his own record showed the number of each to be not far from equal. In remarking upon the prognosis, he alluded to the frequency in the case of females of an opening from the intestine into the vagina, the latter serving as a channel for fecal matters. In a case mentioned to him by Dr. Mussey, the patient was still living, aged 20, in whom such opening existed. In males an opening is sometimes found from the rectum into the membranous portion of the urethra, as in a case reported by Dr. York. In this case the opening made by the operation healed, and the fecal matters found their way again by the urethra. The child lived about twenty months; the opening into the urethra was about the size of a common bougie. Dr. Cabot stated that he had never known the operation prove ultimately successful; and Dr. Jackson added that Dr. J. C. Warren had told him, some years since, that he did not remember a single successful case. Dr. Walker had mentioned to him one that had succeeded.—*Boston Medical Journal*, vol. lvii. p. 240.

### EXCERPTA MINORA.

*Dislocation of the first Phalanx of the Thumb on the metacarpus.*—Dr. Cutter thus describes a mode of reduction which has several times been put into force by Dr. Crosby, after various other plans had failed:—"I placed the patient in a chair, and took another by his side, both of us facing the same way. An assistant sat behind us to hold the boy's (eight years old) elbow fixed. I then took hold of the metacarpal bone (of the thumb of the left hand) with my right hand, my forefinger passing between his thumb and forefinger, and my thumb resting on the top of the metacarpal bone, with its end touching the dislocated end of the phalanx. With my left hand I tipped the phalanx back, until it stood perpendicularly on the metacarpal bone; then pressing the phalanx forward by the end of my thumb, it was readily carried by flexion into place."—*Boston Journal*, vol. lvii. p. 174.

*Sore Nipples.*—A correspondent of known experience and judgment strongly recommends equal parts, by weight, of glycerine and tannin as the best application for sore nipples. It is also an excellent remedy for chaps and excoriations of

other parts. The tannin dissolves readily in the glycerine.—*Ibid.* p. 187.

**Ossaceous Union of Teeth.**—The editor of the *American Journal of Dental Science* observes, that he has frequently seen examples of ossaceous union of teeth, but that the most remarkable specimen was recently presented to him. "It is a dens sapientie and a small supernumerary tooth. The side of the crown of the latter is united to the grinding surface of the crown of the former; the root of the supernumerary pointing backwards and upwards. The last-mentioned tooth must have been developed from a sac given off from the coronal portion of the sac of the wisdom tooth, and a union of the enamel membrane of the two teeth must have taken place previous to the deposition of earthy salts in the cells of the enamel fibres."—*Ibid.* p. 208.

**Treatment of the Drowned.**—Dr. Cornstock is surprised in the recent discussions on this subject no mention has been made of applications to the nose. In one of the instances of longest submersion on record, the first signs of recovery followed the pouring  $3\frac{1}{2}$  of sp. ammon. aromat. into the nostrils, and thrusting a feather dipped in ammonia as far as it would go. Dr. Wistar declared that the most successful treatment consisted in stimulating enemata, suppositories of mustard and red pepper, and a plaister of these substances applied to the anus and perineum. He believed that life lingered longest in this part of the body.—*Ibid.* p. 254.

**Delivery impeded by Enlarged Fetal Kidneys.**—M. Chevance relates a highly interesting case in which delivery was accomplished only after eventration, on account of great hypertrophy of both fetal kidneys. The pelvis was normal, and the child was premature; but the kidneys together weighed 250 drachms, while the rest of the body weighed only 612 drachms.—*Union Méd.* 1857, No. 89.

**Ice in Intestinal Obstruction.**—Mr. O. Masson relates two additional examples of the efficacy of this. Referring to his thesis of 1857 for an account of the mechanism, varieties, and diagnosis of internal intestinal obstruction, he here confines himself to a statement of the great benefit derivable from its treatment by ice. This is to be applied to the abdomen, administered as iced water as clysters, and given the patient to drink. A hoop is placed above the abdomen of the patient, and to this is suspended a large caoutchouc bladder, capable of covering the whole surface of the abdomen. If a sufficiently large bladder cannot be obtained, several smaller ones, or several small common bladders, should be substituted. Into the bladder morsels of ice are placed, and are, as soon as melted, replaced by others. The clyster of iced water is to be given three times daily. The general condition must determine how long this practice may be persevered in. In one of these cases relief was obtained thirty-six hours after regular use of the ice, and in the other only after four days.—*Bull. de Thérap.* tome lli. pp. 345—353.

## GENERAL CORRESPONDENCE.

### A NEW METHOD OF TREATING ASPHYXIA.

[To the Editor of the Medical Times and Gazette.]

SIR,—In a former number of your Journal, (No. 385, Nov. 7, 1857,) I described in a concise manner a new method of inducing respiration in cases of asphyxia, and instituted a comparison between it and Dr. Marshall Hall's plan, both with regard to the principles and practice. I also stated some of the advantages which my method appears to possess over the various measures heretofore employed for the restoration of persons apparently dead from apnoea. I subsequently, in No. 387, November 28, 1857, by way of illustration, brought forward the case of a child still-born restored to animation by the method there recommended. I now propose to give you briefly the results of some experiments on the dead body, which were undertaken with the view of elucidating the subject of artificial respiration.

The apparatus employed was very simple, and consisted of three tubes: one of glass, to be passed into the trachea; another a bent barometer tube, graduated; and these two connected by a piece of India-rubber tubing.

The following was the mode of using the apparatus:—

The glass tube was passed through an aperture made in the

trachea, and firmly secured in its place by a ligature. A small quantity of coloured spirit was poured into the bent barometer tube, which was retained in an upright position on a level surface by an assistant who carefully noted the height of the column of fluid.

Trials were made on persons of both sexes, and of ages ranging from a few weeks to fifty-four years; and at a length of time after death which varied from one hour and a half to two days.

The object of the first experiment was to determine what would be the effect of pressure upon the front of the chest by the hand alone.

The body was placed on its back supported by a small pillow or folded article of dress, the head resting on its side.

Pressure being applied, the fluid in the bent tube immediately rose (see fig. 1), and when the pressure of the hand was removed, the fluid fell slowly to its previous level, proving—

1stly. That air had been expelled from the lungs;

2ndly. That it returned, though slowly, in consequence of the feeble elasticity of the chest.

3rdly. That the actual capacity of the chest was not increased by this mode of procedure.

The second experiment was to ascertain the influence of the *Postural Method*.

FIG. 1.

FIG. 2.

a. Natural level of fluid. & Height to which fluid rose by pressure on the chest. c. Point to which the fluid receded in the first leg of the instrument by the drawing of air into the lungs when the chest was expanded by my method.

Continuous line represents the ordinary state of the chest. Broken line represents the depression of the chest under pressure. Dotted line represents the enlargement of the chest, produced by the forced action of the muscles of inspiration. The space between the continuous line and the broken line indicates the extent of respiratory movements in the postural method. The space between the dotted line and the broken line indicates the extent of respiratory movements in my method.

The subject being placed upon the face, the fluid rose in the bent tube as in the first experiment; and on turning the body (a) on the side, and a little beyond the column of fluid fell slowly to its former level.

The result of these two experiments exactly corresponds, proving that air can be expelled from the lung, whether by pressure of the hand, or by the altered position of the body, and that the air returns into the chest by means of the elasticity of the parietes, although this is effected but feebly.

It is obvious that by this method the actual capacity of the chest is not enlarged.

(a) The body must not be turned into the prone position by means of the arms, as in that case the chest would be expanded.

The third experiment was for the purpose of testing on the dead body the method which I venture to lay before the Profession.

The position of the subject was the same as in the first experiment, viz., supine, with the head resting on its side. The height of the column of fluid being carefully noted, the arms of the patient were extended upwards and outwards by the side of the head, so as to raise the shoulders and put the pectorals on the stretch, elevate the ribs, and consequently open the chest. The fluid in the bent tube rapidly fell. The shoulders and arms were then pressed down upon the sides of the chest, and immediately the fluid rose up as much above its usual level as it did in the foregoing experiments, demonstrating—

1stly. That the actual capacity of the chest was increased, and air drawn into the lungs by the constrained action of the muscles of respiration upon the moveable walls of the thorax.

2ndly. That expiration was produced by pressing the arms and shoulders down upon the chest.

I am, &c.

HENRY R. SILVESTER, B.A. M.D. Lond.  
High-street, Clapham, Jan. 8, 1858.

### RAPID DELIVERY.

[To the Editor of the Medical Times and Gazette.]

SIR,—Should you think the following case of any value in a medico-legal point of view, perhaps you will find a place for its insertion in your columns.

On the 1st ult. I was requested to attend a labour, some four miles distant. On arriving at my destination, I found that the case was a primipara, and that labour had been progressing for some three hours; but about half an hour previous to my arrival the membranes had ruptured, followed by an ordinary pain, and that no further pains had been felt. I waited in the room some ten minutes, but finding no pains present, I set it down as one of those cases in which the membranes rupture early, and a lingering labour ensues; and finding that an examination per vaginam was objected to at present, I directed that I should be called as soon as labour again commenced, and advising, if she found it practicable, that she should walk gently about, supported by the nurse.

I had hardly made myself comfortable in the parlour, before I was hastily summoned up stairs, and was informed by the nurse that "baby was born."

It appears that at her last pain, now some forty minutes ago, she "felt something come away," and the nurse fancied she "heard a baby cry," but no notice was taken of either circumstance, the completion of the labour not being expected so soon. The child was to all appearance dead, but I deemed it advisable to try every measure for its restoration, and did so for half an hour, but without avail.

I may add that the person was a respectable farmer's wife, and great was her grief when she found the position of affairs.

Should the like case have happened to one of the class of "unfortunates," I will leave your readers to draw their own conclusions as to the apparently "suspicious circumstances of the case."

I am, &c.

ARTHUR WIGLESWORTH.

Blakeney, Gloucestershire,  
Feb. 1, 1858.

### POST-PARTUM HÆMORRHAGE.

[To the Editor of the Medical Times and Gazette.]

SIR,—In some of your recent numbers I have read with interest letters from correspondents on a subject of the greatest possible practical importance, viz. Post-partum Hæmorrhage. In the year 1840, I adopted a mode of treatment which in seconds, rather than minutes, answered every indication, and more than realized my most sanguine expectations. As this has been tested now by upwards of seventeen years' experience, not confined to my own practice, but shared by the majority of practitioners with whom I have come in contact during that time, I give it to the Profession with confidence, as an unfailing remedy.

It consists of an injection into the rectum of 4oz. of turpentine, 4oz. of cold water, and a handful of common salt, forcibly retained by means of a folded napkin firmly pressed against the anus, until violent bearing down or tenesmus, is induced. The object is, *first*, to produce continuous reflex action; an action that will last sufficiently long to prevent all risk from relaxation of the womb, since the bearing down of the gut will be necessarily accompanied by the contraction of the womb. *Secondly*, as turpentine, by its stimulating properties, acts as a powerful restorative to the whole system, it becomes a matter of the greatest importance in the selection of the agent chosen for the purpose of inducing reflex action, to make use of one possessing such properties. *Thirdly*, the anti-hæmorrhagic properties of turpentine may possibly also prove useful. Want of time prevents my entering into the subject as fully as I should have wished to do; but if you will oblige me by the immediate insertion of this, I shall take an early opportunity of supplying you with the particulars of my first case, in which all the ordinary known remedies had failed, and my reasons for adopting the practice mentioned.

I am, &c.

Carlisle, Feb. 2nd, 1858.

THOMAS ELLIOT, M.R.C.S.L.

### THE NARCOTIC PRINCIPLES OF THE "NATIONAL REVIEW."

[To the Editor of the Medical Times and Gazette.]

SIR,—Last week you quoted from the *National Review* a paragraph about narcotics, which could, as I presume, only have been written under narcotic agency. I like the *National Review*, in its own department, but like a sprightly barnacle in the Royal Society, I fear it to be an exquisite fish out of water, when it endeavours to connect the "metaphysical" nothing with the physiological laws, the demonstrable. I know of no positive facts about the effects of Hashish, or thorn-apple, but I ask for the proof that Siberian fungus, by which is meant, I suppose, the *Amanita Muscaria*, produces insensibility to pain without interfering with consciousness. So I do not wonder at the (?) with which you embellished the assertion. I know once a gentleman who had seen a great many people affected with the *Amanita Muscaria*, and the impression on his mind was, that he had never witnessed such profound or heavy drunkenness from any alcoholic drink. The effect of the common puff-ball, as a narcotic, were first described by myself; I have used it more than any other experimentalist, and I am, probably, the only man who has been under its influence. But that "the common puff-ball stops all muscular action, without interfering with consciousness," is to me a novelty with which it would be pleasant to be better acquainted.

How *Cocculus indicus* affects the human subject I cannot say; any way, it makes animals profoundly intoxicated. But whether a dumb animal, dead drunk, is as intellectual as in more sober moments, remains an open question.

The discovery that cocoa has "the wonderful power of sustaining muscular strength in the absence of food, and of preventing the wasting of the tissues of the body during the most prolonged exertion," is an acute and remarkable observation. But is it not overstrained, and might not exertion be carried too far even for cocoa? Take for instance the feat of walking a thousand miles in a thousand hours.

I do not wish to carry the opposition argument further, except to state, that it is not the general rule that "tobacco suspends mental activity," or that "opium increases it a thousandfold." To some men tobacco gives great activity of thought; to others opium, in any dose, and at any time, is a stupifier. In excess, the effects of the two narcotics are essentially the same.

I am, &c.

B. W. RICHARDSON.

12, Hinde-street, Feb. 3, 1858.

**CITY LUNATIC ASYLUM.**—At a special Court of Common Council, Mr. W. Cox brought up the report of the Local and Finance Committee respecting the proposed Lunatic Asylum for the city of London. The report of the Committee stated that, assuming accommodation would be required for 200 patients, the cost would be about £50,000; and the Committee recommended that the amount should be raised by a county rate. The report was adopted.

## REPORTS OF SOCIETIES.

## ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, JAN. 26, 1858.

Sir C. Locock, M.D., President, in the chair.

A paper by Mr. HAYNES WALTON was then read.

## VASCULAR TUMOUR IN THE ORBIT, OF MANY YEARS' STANDING,

AND LATTERLY PRODUCING THREATENING SYMPTOMS, SUCCESSFULLY TREATED BY THE INJECTION OF TANNIC ACID.

A lady, twenty years of age, was sent to Mr. Walton by Mr. Square, of Plymouth, in 1856, on account of a vascular growth in the left orbit. The eyeball was prominent, and turned slightly upwards and outwards, restricted in motion, and incapable of being directed inwards. The lower eyelid bulged, and was slightly discoloured, especially towards the nose. By turning down the tarsal margin, there was exposed a growth, having the appearance of a congeries of veins attached to the eyeball, and which was evidently only a part of a larger mass. Pressure emptied it, the act producing pain, and re-distension took place very slowly. The chief subjective symptoms were, pain on the slightest exertion, and in extremes of temperature and during the catamenia; inability to lie down, in consequence of unpleasant sensations in the orbit and head; vision nearly extinct. The affection was congenital. Very soon after birth, slight swelling of the lower eyelid was discovered. At the age of thirteen it attracted attention generally, and besides being larger, there was a bluish tint of the integument. Reading or writing for some hours always caused temporary enlargement, and heightened the colour. Mr. Walton diagnosed the tumour to consist chiefly of dilated and tortuous veins, and came to the conclusion that it was limited to the anterior and inner part of the orbit, and did not pass posteriorly. He resolved to treat it by the method of injection, and sought for an agent which might be safely used. Some experiments with the perchloride of iron caused him to reject it as unsuitable, from the tendency of the free acid which it contains to produce sloughing, or at least severe local action—a result to be avoided in such a situation. Ultimately, he determined to employ tannic acid, as an agent not possessing caustic properties, and one readily producing coagulation of the blood. A strong solution of this substance was thrown in with a syringe. There was rapid cessation of the hæmorrhage which followed the preliminary puncture, and the solidity of the tumour showed the extent of the coagulating action. Considerable swelling of the eyelid and chemosis of the conjunctiva ensued, accompanied with local pain and slight constitutional disturbance, but this was of short duration. A slight incision deemed necessary in the tumour was in a day or two followed by a dark brown discharge. Later an abscess formed under the lower eyelid, and was evacuated by an external incision. The eyelid was long paralysed, but ultimately the movement completely returned. The discharge from the tumour continued for many weeks, varying in quantity, and several times pain and local irritation preceded the escape of fibrinous clots; and twice a small cretaceous mass was discharged. When the patient left town, just three months after the commencement of the treatment, there was no longer any secretion from the seat of the disease or the abscess, and all trace of the tumour had long disappeared. The eyeball had fallen back nearly to the natural plane, although all its movements were not perfect. It could be directed downwards and outwards naturally, but not turned fully inwards, nor could it be raised to more than half its proper extent.

Mr. DIXON asked Mr. Walton whether he thought the termination of the case bore out the superiority of tannic acid over other injections. It appeared that inflammation, and subsequently the formation of abscess, followed the injection, very much as in the case of alum and other solutions.

Mr. ROBERT TAYLOR said he had seen the case described by the author, and could state that the inflammation was never at any period so excessive as to require surgical interference, or to endanger in the least degree the safety of the eyeball. The result had shown that nothing could be more

satisfactory than the method employed. From what he had seen of the case, he was induced to adopt the same method in a case that came under his own care early last summer. He injected half a drachm of saturated solution of tannin, and the result was, sufficient inflammation to consolidate the globe, and to check the progress of the disease without endangering the parts.

Mr. SPENCER WELLS said, the author objected to the use of perchloride of iron, because it produced too speedy coagulation of the blood. That altogether depended upon the strength of the solution. If the solution was of the specific gravity of 45, according to the French *aréomètre*, coagulation took place almost immediately; but if the specific gravity was from 20 to 30, the coagulation would take from ten to fifteen seconds, allowing sufficient time for the fluid to pass along the canula before the coagulation took place. He had found that in passing an ordinary trochar and canula into the tumour, and then affixing a syringe containing the solution, coagulation was apt to take place in the canula. To avoid that, Mr. Blaise had modified the French instrument, making the canula sufficiently sharp and hard to act as a needle. There was a screw piston, and the syringe was made of glass and graduated. The piston could be screwed down till the needle canula was quite full, it was then passed into the tumour, and by turning the handle, as many drops as were required could be injected, without the fear of any retardation in the canula. He had used the instrument in several cases with beneficial results. In one case, which he believed was an encephaloid tumour of the ilium, he injected ten drops in four different punctures, and the result was very successful, the growth having been entirely arrested, and the tumour converted into a hard, painless, moveable tumour, which was diminishing in size. In other cases of *nævi* and *varix* he had employed the same means successfully.

Mr. HULKE said, he had made several experiments with perchloride of iron, according to the French formula, and had never found any difficulty arising from the coagulation of the blood in the canula. He had injected the solution into the circulation of dogs, and the result was, that the blood very speedily coagulated, and death immediately ensued. During the last year he had seen four cases of venous *nævi* on the eyelids, three of which were treated with perchloride of iron, not in the way of an injection, but by dipping a piece of silk in the solution, and passing it through as a seton. A little suppuration was excited in the track of the thread, but on the second or third day the whole growth became solid, and no unpleasant effects were produced.

Mr. CHARLES HAWKINS recommended the introduction of a probe coated with nitrate of silver, and mentioned a case of *nævus* in which that method had been successfully adopted, the probe having been introduced at different times in different parts of the tumour, which ultimately disappeared.

Mr. WALTON, having briefly replied,

A paper by Dr. ROBERT LEE was then read.

## ON THE MEMBRANA DECIDUA WHICH SURROUNDS THE OVUM IN CASES OF TUBAL GESTATION.

The author commenced this communication by citing various authorities to prove that the common opinion from the days of William Hunter to the present time was that the decidua, or outer surface of the secundines, belong to the uterus, and not to the ovary, or that part of the conception that is brought down from the ovary; and that in cases of extra-uterine pregnancy, a deciduous membrane was still to be found in the cavity of the uterus. But a case is recorded in the seventh volume of the *Medico-Chirurgical Transactions*, in which the uterus is stated to have been "considerably larger than we observe that organ to be in the unimpregnated state, even in women who have borne several children. On laying it open, the uterine vessels were observed to be very large but empty, and there was a great quantity of gelatinous matter in the cavity and neck of the uterus. When this was washed off, the internal surface of the viscus looked very vascular, having been highly injected; but there was not the least appearance of a decidua." A second case is recorded in the seventeenth volume of the *Medico-Chirurgical Transactions*, in which the author himself was surprised at finding that "no organized deciduous membrane lined the cavity of the uterus, but the whole of it was coated with a thin layer of albumen." This case occurred

in 1829, and the preparation was placed on the table of the Society in 1832; but until 1836, when another example of tubal gestation came under his observation, it does not appear that he made any attempt to determine whether the ovum in the Fallopian tube was surrounded by decidua. The two preparations were then examined together, and a description of the appearances observed was published in the *Medical Gazette* for 1839-40. These cases, with four others which have subsequently come under his observation, are the subject of the present communication. In Case 1, on opening the tube, and examining the different parts of the ovum, he found a deciduous membrane everywhere surrounding the chorion, and closely adhering to the inner surface of the tube, as the decidua usually does to the lining membrane of the uterus. Within the decidua, the chorion, amnion, and embryo were distinctly seen. The uterus was larger than natural, and there was no appearance of decidua lining its internal membrane. In Case 2, on carefully examining the ovum contained in the right Fallopian tube, it was evident that a deciduous membrane everywhere surrounded the chorion, and adhered to the inner surface of the tube. The placenta, which was situated at the extremity of the ovum nearest the uterus, was seen covered with the decidua, and coagula of the fibrine of the blood were traced from the interstices of the placenta through the decidua into veins in the thickened muscular coat of the tube. The uterus was considerably enlarged, and its inner surface was coated with a very thick layer of yellowish-white soft substance. There was no trace of any arterial or venous canal in this cavity. In the third case, the fetus had reached the age of six months, and was contained in a cyst which adhered to the omentum and intestines and to the surface of the uterus, and contained a great quantity of thin, fluid-like pus. The walls of the uterus were healthy, and the cavity empty. There was no decidua or substance of any kind coating its inner surface, but a decidua was attached to the placenta in the usual manner. In Case 4, the greater part of the ovum had been removed, but still the decidua reflexa could be very distinctly seen covering a considerable portion of the villi of the chorion. In the uterus was found a coating of considerable thickness, and of a yellowish-white colour, in which neither arteries nor veins could be traced. Case 5 is also one in which only a portion of the decidua was found in the tube. In Case 6, the substance lining the cavity of the uterus resembled the fibrine of the blood, and was of a red colour at its upper part; where it had been detached from the surface of the uterus, the lining membrane presented a perfectly natural appearance. The embryo was enclosed in the amnion, with the vesicula umbilicalis remarkably large. The cells of the placenta and the villi of the chorion were distended with coagulated blood, and surrounded by deciduous membrane. By a careful dissection subsequently made, the decidua was found to consist of placental decidua, decidua vera and reflexa, with a decidual cavity. An enumeration of the preparations in St. Bartholomew's and Guy's Hospital museums is appended, illustrating the pathology of Fallopian tube conception. In the former there are five examples, and of one of these the museum catalogue states that "the outermost membrane enclosing the fetus has all the character of decidua. Besides this membrane, the amnion and chorion are distinct; the fetus and umbilical cord are also perfect." In the opinion of the author, there can be no doubt that a decidua surrounds the ovum; and though none of the other preparations have been dissected with the view of ascertaining the point, yet in all the separation of the ovum from the inner surface of the tube has been carried to an extent sufficient to enable us to demonstrate the fact. There are thirteen preparations in Guy's Hospital museum. The author was permitted by Dr. Wilks, the conservator of the museum, to make a minute examination of the ovum in one of these, which had escaped entire through a rent in the Fallopian tube. He had the satisfaction not only to discover the vesicula umbilicalis, but to see the chorion completely surrounded by decidua, as in the case described at the early part of this communication. There can be no doubt that if the ova in these preparations were submitted to a similar examination, a decidua would be found in all, surrounding the ovum in the Fallopian tube. He did not wish to express an opinion on the nature of the membrane or substance found coating the inner surface of the uterus in the greater number of these preparations, which has been almost

universally considered to be decidua since the days of Dr. William Hunter, although no blood-vessels in it have been discovered. His great object was to demonstrate the existence of a decidua around the ovum in cases of tubal gestation.

Dr. JOHN CLARKE called the attention of the Society to one of the preparations of Fallopian-tube gestation laid upon the table. The uterus, he said, was laid open, exhibiting, as he thought, a true deciduous membrane—not the membrane that was thought formerly to be formed by lymph poured out, but (as understood of late years) the inner membrane lining the uterus, and presenting a peculiar tubular appearance. In the neck of the uterus there was the usual secretion in the glands. It was quite clear that in the Fallopian-tube there was no appearance of a strictly speaking deciduous membrane; there was nothing but the fetus, the amnion and the chorion lying against the inner coat of the tube. He did not venture to state, however, that in no case was a deciduous membrane formed round the ovum in Fallopian tube gestation; but he regarded the cases in which there was such a membrane as indicating an effort of nature to accommodate the part to a new function, which it was not originally intended to perform. The ovum had escaped from the ovarium, and lodged in the tube. Nature did not set up the inflammation, as in cases where foreign bodies existed; for this was not, strictly speaking, a foreign body, but a living body, intended by nature to be matured and brought into the world, and she accommodated, as far as possible, the tube to the purposes of the uterus; and accordingly there was a certain membrane thrown out somewhat resembling a deciduous membrane, but, as appeared upon close microscopical observation, totally differing from the decidua in the uterus, having, however, certainly the function for a short time of sustaining the life of the ovum. The preparations exhibited did not appear to him (Dr. Clarke) to support the views of the author, since in almost all of them there was a deciduous membrane in the uterus, whether called lymph or shreds; and in those cases where it was not found the uterus was large, and there was some statement of uterine action, followed by the discharge of a membrane or fluid; and it was but reasonable to suppose that in those cases the deciduous membrane might have escaped.

Dr. TYLUS SMITH said he did not know that any previous observer had collected so many cases of extra-uterine gestation, with a view to point out the existence of decidua, or a membrane like it in the tube, as the author; but the fact he believed to be more generally known than Dr. Lee appeared to suppose. In 1856, he (Dr. Smith) published a systematic course of lectures on midwifery, and his observations were in their purport exactly similar to those of Dr. Lee, namely, that in the cases under consideration, a decidua, or a membrane similar to it, was found in the Fallopian tube, and that generally, but not always, a decidua was found in the uterus. When the ovum became attached to the lining of the tube, there was no difficulty in supposing that the mucous membrane in that situation would, as far as its organization allowed, behave as the mucous membrane of the uterus would have behaved if the ovum had passed through the tube, and attached itself to the uterus.

The PRESIDENT said he remembered many years ago, when a student in Edinburgh, being at the Queensborough Hospital, when Mr. Syme was in the act of opening the body of a young woman who had died of small-pox. In the operation there was discovered what at first sight appeared to be a cyst, at the edge of the pelvis, which it turned out to be a case of extra-uterine gestation. He felt interested in examining the ovum; it appeared to be a transparent cyst with a neck attached to the Fallopian tube, and was floating above the brim of the pelvis amongst the intestines. It was opened carefully, and, most undoubtedly, there was neither a decidua to be seen, nor anything like it. There was simply the fetal part of the ovum, the two membranes that are always considered fetal membranes, and the regular coat of the Fallopian tube itself. The connecting neck was about an inch and a half long. On cutting into the uterus, he remembered Mr. Syme saying, "Here is Hunter's membrana decidua." It was not an organised membrane, since the ovum had never been there. In many cases mentioned by Dr. Lee, there was what was called a cribriform membrane, and even in his own cases there were remnants and appearances similar to those of a deciduous membrane in the state in which it would almost necessarily be if the ovum had never reached the uterus.

The explanation of the apparent difference in these cases was the gradation of pregnancy. In normal pregnancy Hunter's theory was no doubt right; but in extra-uterine foetation a membrane was formed, which was never properly developed because it was not required. The case was considered to be something like that of menstruation, which some believed to be nothing but imperfect or disappointed pregnancy. In Hooper's Morbid Anatomy there was a representation of the interior of the uterus of a woman who died accidentally during menstruation; and the condition of the lining membrane of the uterus was very similar to what was observed in the uterus when pregnancy occurred in the Fallopian tube. He concluded that that was the explanation: that when the ovum never reached the uterus the membrane in the uterus was never a perfect one; but at the same time the ovum would never go on to perfection without having a substitute for the membrane in the locality in which it was found—which substitute could scarcely be called a deciduous, but rather a fortuitous membrane.

## THE PATHOLOGICAL SOCIETY.

TUESDAY, JANUARY 19.

Dr. WATSON, President, in the chair.

(Concluded from page 146.)

Dr. BEALE, for Dr. EALING of Hereford, showed a specimen of

### IMPERFORATE RECTUM.

The infant had died of obstruction of the bowels when six days old. There was an opening at the anus into which the finger could be passed for an inch. An attempt had been made during life to enter the bowel with the finger, but although the extremity of the pouch was easily perforated no meconium was obtained. At the autopsy the rectum was found distended with meconium, and placed a little above the extremity of the anal pouch. The finger had passed by the side, but had not entered the bowel. The calibre of the gut was wholly obliterated, and the intestine at the part converted into a fibrous band.

Mr. BALLARD exhibited a specimen from a case of

### TUBERCULOUS ABSCESS OF THE ANTERIOR MEDIASTINUM BURSTING INTO THE TRACHEA.

This specimen was from an infant, aged 5½ months at the time of his death, the offspring of a phthisical father, the mother being apparently healthy. From two months old he was noticed to have a slight husky cough, for which, at the age of three months, an application was made to his throat with a sponge probang on two occasions, immediately after the last of which symptoms of croup came on; he was then placed under the care of a homœopathic practitioner during three weeks, without any relief to the symptoms. Mr. Ballard saw him first on Nov. 7, suffering with impeded respiration, hoarseness, and sonorous cough, but no mucus in the throat. Leeches, antimony, and calomel were carefully employed for a short time, but with only partial relief. The symptoms continuing after a month, the propriety of performing tracheotomy was well considered, but the idea abandoned by the advice of Dr. Fuller, who suggested that there was a tumour pressing on the lower part of the trachea. Three weeks before death, and on several subsequent occasions a little purulent fluid was coughed up. He continued to suffer much distress until January 1, when he died rather suddenly.

Post-mortem examination showed in the anterior mediastinum a mass of tuberculous glands, and an abscess, the size of a pigeon's egg, containing softened tuberculous matter, which communicated with the trachea, through its anterior wall, by a ragged opening half an inch in length, the mucous membrane around and above for some distance being much ulcerated. The larynx and the tracheal mucous membrane below it, for the space of more than an inch, appeared quite healthy. The pharynx contained a good deal of purulent fluid, such as was found in the cavity of the abscess. Both lungs were entirely studded with masses of tubercle; the pleura on the right side were adherent. The right side of the heart was distended with dark, semi-coagulated blood, thus confirming the suspicion that the child died of asphyxia, caused by a large quantity of the contents of the abscess being discharged into the trachea.

Mr. CALLENDER showed specimens from a case of

### PERFORATION OF THE SEPTUM VENTRICULORUM.

This specimen was removed from the body of a man, aged 36, who died a few hours after his admission into one of the wards of St. Bartholomew's Hospital. The heart was enlarged from simple dilatation of all its cavities. Just below the aortic valve a circular opening penetrated the septum. Its edges were sharply defined, except that some fringe-like portions of fibrin projected from its upper margin. The endocardium around was thickened. Upon its right side a mass of decolorised fibrin formed for it a valve-like covering, so as to prevent the passage of fluid from the right into the left ventricle. There was a good deal of thickening about the aortic valve, which consisted of only two cusps, evidently of long standing. One of the tertiary branches of the left pulmonary artery was occupied, at its bifurcation, by a globular mass of fibrin. This had been subjected to the action of the blood. Its interior had been hollowed out, and the remaining shell had become dilated, with yielding of the surrounding structures. Beyond this point two other clots were seen. Through one of them the blood seemed to be boring for itself a channel. Had this process been continued, the perforation might have been completed, and the canal restored, narrowed, of course, by such remainder of the coagulum as might still cling to the arterial wall. The remaining clot, round, solid, and, like the others, decolorised, had not been influenced since its first lodgement by the action of the blood. The pulmonary lobules with which this occluded artery communicated were in a state of gangrene. The other organs, with the exception of considerable venous congestion, presented a natural appearance. It seemed not improbable that the perforation of the septum had resulted from endocardial disease, and the appearances noticed in the left lung from the separation of portions of fibrin from the mass which covered the opening thus determined.

TUESDAY, FEB. 2, 1858.

Dr. WATSON, President, in the Chair.

Mr. CALLENDER exhibited a specimen of

### TUMOUR OF THE BRAIN.

In the anterior portion of the right hemisphere was a mass of medullary cancer. No other malignant disease was found in the body. The membranes of the brain were extensively adherent. The subject of the disease was a man, aged 47, who had died after a six months' illness. He had been throughout that time liable to frequent convulsive seizures affecting the left side of the body.

Dr. FULLER next brought before the Society a specimen of

### LARGE FIBRINOUS CLOT IN THE RIGHT VENTRICLE.

A man, aged 19, had for long been subject to chronic bronchitis, often attended by much dyspnoea. When admitted his orthopnoea and lividity were extreme, but these symptoms were mitigated after a few days' treatment. Subsequently, however, he relapsed, became insensible, and so died. At the autopsy in the right ventricle was found an enormous fibrinous clot, which distended every part of it. The centre of this clot had softened, and resembled pus. The lungs showed the effects of chronic bronchitis, but there was nothing in them to account for death. Dr. Fuller was inclined to attribute death to the clot, which had evidently existed for some time.

The President remarked, that it was difficult to explain how these clots could occasion sudden death. He had often seen similar ones, but of smaller size.

Dr. BUISTOWS observed that he had himself, in a volume of the Society's Transactions, published a series of examples of the formation of clots in the heart. It was a mistake to say that they were most frequent in the right ventricle. He had found them in all the cavities, and he thought with almost equal frequency on either side. He also had not found that they caused sudden death. Usually they were found in cases in which the patients had been long in dying; often when a recovery from an almost dying state had taken place a few days before the event.

Dr. QUAIN would remind the Society that Mr. Gulliver had long ago decided, after an extended series of observations, that these softened portions of clots never contained true pus. Dr. FULLER also showed

#### FIBRINOUS EXUDATION FROM A CASE OF DIPHTHERITE.

The child, aged 9, had been suddenly attacked by acute inflammatory symptoms. The tonsils and pharynx were covered by a creamy exudation. Her paroxysms of dyspnoea were extreme, and she was expected to die. In one of the most violent, however, she expectorated the cast exhibited, which had evidently been modelled on the whole pharynx. It measured four inches in length, and was a wide cylinder capable of admitting four fingers. After this most complete relief followed. A bright scarlet rash which had hitherto existed at once disappeared. A rapid recovery ensued. In answer to a question from Mr. Hutchinson, Dr. Fuller stated that the chlorate of potash was not used throughout the case.

Dr. OGLE showed a

#### POUCH CONNECTED WITH THE MITRAL VALVE.

One curtain of the mitral valve was perforated, and the opening was blocked up by a pouch, which had apparently been constructed from the fibrin of the blood.

Dr. OGLE also showed a

#### MUSCULAR CORD IN THE MITRAL VALVE.

One of the chordæ tendinæ was replaced by well characterised muscular tissue. Dr. Ogle had never noticed a similar condition. Both these specimens were illustrated by excellent drawings.

Mr. THOMAS SMITH showed two specimens of

#### ABSCESS IN FATTY TUMOURS.

One, a large one, had been removed from the thigh of a lady about a year after the abscess had occurred. The suppuration had been considerable, and had been evacuated externally. At the time of excision the line of cicatrix through the middle of the tumour was distinctly seen.

Dr. COCKLE showed a preparation of

#### AN ANEURISM OF THE AORTA.

The patient, a man aged 60, had suffered much dysphagia from the pressure of the tumour on the œsophagus. The sac was very large and almost filled with clot. For three days before death there had been no pulsation in the left radial. A pulsating tumour had been noticed during life between the second and third left cartilages. Mortification of the nose had commenced a few days before death, and was rapidly spreading.

Mr. HULME showed an

#### EYE-BALL AFFECTED BY MALIGNANT DISEASE.

A somewhat delicate child, in whose family no history of hereditary tendency to cancer could be made out. The child's health failing, it was determined to extirpate the globe. After removal, a growth of medullary cancer from the posterior part of the globe was found. The lens and cornea were quite transparent, but no trace of retina could be discovered.

### EPIDEMIOLOGICAL SOCIETY.

MONDAY, DECEMBER 7, 1857.

Dr. GREEN, in the Chair.

Dr. ODLING read a paper

#### ON THE DISTRICT MORTALITY OF LONDON.

The author calculated logarithmically the annual rate of increase of population in each of the 36 metropolitan districts, between the census of 1841 and that of 1851, according to the equation  $r = \sqrt{\frac{m}{p}}$ ; and presuming the same rate to have continued since 1851, ascertained the mean population of each district in the year 1856. The mean annual rate of increase was greatest in Islington, where it amounted to 5.62 per cent., and least in St. James's, Westminster, where it was estimated at 0.27 per cent. The mean of the entire metropolis was 1.94 per cent. The calculated population of St. Pancras in 1856 amounted to 189,337, and was greater than

that of any other district; while the population of Hampstead amounted only to 13,060, and was less than that of any other district. The density of population was greatest in the Strand district, which had 258 persons to an acre, and least in Lewisham, which had only 2.4 persons to an acre. The lowest mortality occurred in Camberwell, Lambeth, and Clerkenwell, where the death rates per 1000 were 18.57, 18.71, and 18.97 respectively; the highest in St. Olave, Southwark, Whitechapel, and Greenwich, where the death rates per 1000 were respectively 55.25, 26.60, and 25.58. The extremely high death rate of St. Olave, Southwark, was evidently due to its containing Guy's and St. Thomas's Hospitals. The mean mortality of the metropolis was represented by a death rate of 21.83 per 1000. From an examination of the entire results it appeared that no district having a high reputation for salubrity had a high death rate, but that several districts having had bad reputations enjoyed a comparatively low mortality, as instanced particularly in Lambeth, Bethnal Green, St. Luke, and Bermondsey. The death rate of any district did not appear to have any specific relation with its elevation or with its density of population. No calculation was made of the mean individual wealth of the residents in each district, and consequently no comparison of wealth with mortality, but it was observable that the poor parishes of Lambeth, Clerkenwell, Bethnal-green, and St. Luke had lower death rates than the rich neighbourhoods of St. George Hanover-square, St. Mary-le-bone, and St. Martin's-in-the-fields. Dr. Odling also made calculations of the death rates from epidemic disease, and of the proportions which these death rates bore to the general death rates. In his own parish of Lambeth, moreover, he ascertained that the entire death rate varied from 12.33 per 1000 in the Brixton subdistrict, comprising 17,506 inhabitants, to 21.69 per 1000 in the Lambeth Church subdistrict, comprising 18,390; and that in his eight subdistricts the total rate of mortality increased precisely as the proportion which the infant mortality bore to the entire mortality increased.

### EAST INDIA COMPANY'S SERVICE.

#### QUESTIONS PUT AT THE EXAMINATION FOR ASSISTANT-SURGEONS.

January 11 and 12, 1858.

##### ANATOMY AND PHYSIOLOGY—MR. BUSK.

1. Describe fully the structure, functions, and relations of the sympathetic system of nerves, noticing its minute anatomy.
2. A line being drawn from the symphysis of the lower jaw along the lower border of the ramus, another along the anterior border of the sterno-mastoid muscle, and a third from the symphysis of the lower jaw, to the upper border of the sternum in the mesial line; describe the parts contained within the triangle thus formed.
3. Enumerate the excrementitious substances met with in the human subject, and describe the sources whence they are derived, and the various modes in which they are eliminated from the system, noticing more particularly the chemical composition and character of urea, and the mode of procedure for its detection when present in the blood.
4. Describe the human blood and the changes it undergoes when removed from the course of circulation, both within and without the body, noticing the circumstances by which its coagulation is effected in either case respectively.
5. Describe the different regions into which the abdomen is divided, and enumerate the parts contained in each.
6. Describe the peculiarities of the mucous membrane in the different portions of the alimentary canal, commencing at the mouth.
7. Define the following terms:—Reflex action, centripetal impression, complementary nutrition, homologous organs or parts.

##### MEDICINE—DR. WALSH.

1. Describe the anatomical characters and mode of progress of circumscribed (or nodular) apoplexy of the lung. What are its symptoms and physical signs; and what the diseases of which it is a recognised effect?
2. What are the signs of enlarged spleen? Point out the

differences in the enlargement, according as it occurs in fevers, in leucœmia, and in organic diseases of the viscus itself.

3. Describe the course and symptoms of uncomplicated measles.

4. What are the premonitory symptoms, actual phenomena, and immediate sequels of an apoplectic seizure, depending on cerebral hæmorrhage?

5. Comment on the prognosis, immediate and remote in—(a) a first attack of rheumatic pericarditis; (b) acute morbus Brightii.

6. Enumerate the more striking characters of the urine in—(a) chronic pyelitis (inflammation of the mucous membrane of the infundibula and pelvis); (b) severe chorea; (c) chronic cystitis; (d) saccharine diabetes.

7. Give the symptoms, signs, modes of spontaneous termination, and diagnosis of abscess in the iliac fossa (unconnected with parturition.)

8. How would you treat—(a) congestive menorrhagia; (b) poisoning by corrosive sublimate; (c) eczema impetiginodes of an extremity; (d) angina pectoris? [Write prescriptions in Latin, without using abbreviations, for any two of the drugs you may recommend.]

#### SURGERY—MR. PAGET.

1. Describe hæmorrhoids, external and internal, in their ordinary and their inflamed states; and the plans of treatment, palliative and curative, appropriate for each kind. In this and other cases write prescriptions for whatever medicines you would recommend.

2. Describe the most frequent appearances of infantile syphilis, and the appropriate treatment.

3. Describe the scrofulous, or tuberculous, disease of the testicle, tracing it through its several stages, and state especially the characters by which you would distinguish it from syphilitic disease, common chronic inflammation, and gonorrhœal inflammation, of the same organ.

4. What are the principal points to which your attention would be directed in selecting a site for a general hospital? Would you, or would you not, in such an hospital, appropriate separate wards to cases of accidents, operations, and certain diseases? State reasons for whichever plan you would adopt.

5. What are the chief marks of distinction between gonorrhœal rheumatism and common rheumatism, and the chief consequences to which the former disease may lead?

6. Describe briefly the principal varieties of dislocation of the humerus, and the characters by which each may be distinguished from (1) fracture through the anatomical neck of the humerus; (2) fracture through the surgical neck; (3) fracture of any part of the scapula.

7. Describe a carbuncle in the several stages of its progress, when not subjected to any active local treatment.

8. What are the general and the minute characters of "fibrous tumours" of the uterus? What changes do they usually produce in the uterus when they grow (1) in the mid-substance of its walls; (2) near its cavity, at the fundus; (3) in or near the vaginal portion of the cervix? What is the corresponding disease in the male?

#### NATURAL HISTORY, &c.—DR. HOOKER.

Answer five or more of the following Questions.

1. Describe in general terms the structure and functions of leaves; in what respect are they analogous to those of bark.

2. Give examples of active principles being present in the bark and leaves of the same plants, but absent or rare in their other organs; upon what peculiarities of structure may this depend?

3. What are the principal modifications of inflorescence? Give examples.

4. What are the structure and functions of pollen; how is it developed, and how does it act on the ovule?

5. The term fruit includes different organs when applied to the apple, nut, plum, strawberry, pine-apple, and fig; what are the organs common to all, and what are peculiar to each of these?

6. What are sago, tapioca, arrow-root, tous-les-mois' manioc, and revalenta; what plants produce them, and how are they procured from those plants?

7. What are the milk, meat, shell, eyes, husk, and coir of the cocoa-nut? define them botanically.

8. What is diastase? give examples of its action during the

life of plants; and of its importance in an economic point of view.

9. What are the principal animal, vegetable, and mineral acids or irritants, and what their sources?

10. What are the principal oceanic currents; and how do any of them influence the climates of the great continents?

11. How do the climates of the east and west coasts of England differ; and what causes the differences?

12. How would you obtain a frigorific mixture artificially? How and under what circumstances may you be able to make ice when the temperature of the air is above 32°?

13. Describe in general terms an electrical machine and a galvanic battery, explaining the principles upon which they are constructed.

14. What are the general principles upon which the science of Geology is based?

15. Describe shortly the reproductive organs of birds, fish, insects, and arachnida.

16. What animals produce sponge, honey, coral, cuttle-fish bone?—and what are these several substances?

17. Describe in general terms the development of the feathers of a bird, the shells of a chelonian, mollusc, and crustacean, and the scales of a fish.

18. Define the terms archetype, vital action, organic function, absorption, assimilation, and sensation.

#### TESTIMONIAL TO DR. M'WILLIAM.

THE following are the speeches of Sir John Forbes and Dr. M'William at the meeting alluded to in a former column.

#### SIR JOHN FORBES'S ADDRESS.

DR. M'WILLIAM.—It is with the greatest pleasure I have accepted the honourable office of being the medium of conveying to you, from my brother Medical officers of the Navy, this splendid testimonial, which, in the words of the poet, may be said to be twice blessed,—honouring them that give, and him who receives. The inscription on this splendid salver concisely tells the story of the events closed by the present proceedings, noting briefly your merits, your noble exertions in the cause of your naval brethren, and the high and just sense of both entertained by them. Although the special cause for conferring the present honour as you is here stated to be your successful labours in the cause of Medical Reform, and especially in obtaining ward-room rank for the Assistant-Surgeons, it can be doubted by no one acquainted with the circumstances, that your previous distinguished exertions in the river Niger and in the Cape de Verd islands bore a part in exciting the feelings which have found issue in this precious gift. That passage of your life in the Niger, extra-professional no doubt, yet closely connected with our noble Profession as *preservative of life*, has always struck me as one of the noblest instances of civil heroism; and I cannot resist the temptation of re-stating it in the words in which it was recorded at the time in one of our Journals, by one of your admirers:—"There are few of our Readers but must remember the melancholy impression made on the public mind by the disastrous result of the expedition to the Niger, when this was made known in England through the newspapers. And none who remember this can forget that pathetic passage in the story, which represented the noble conduct of the Surgeon and Geologist of the expedition, when left alone, in the far recesses of the Niger, amid their heroic companions all stricken to death or to death-like helplessness by the fatal fever of the country. In this trying conjuncture, when the salvation of all on board depended on the speedy removal of the ship from her actual position, Dr. M'William took the navigation on himself, steering with his own hand and piloting the vessel through all the intricacies of the river, while his companion worked the engine below. There is something very affecting, we had almost said sublime, in the picture thus presented to the imagination of these two solitary men of science assuming offices so foreign to their past habits and knowledge, stripped of all exterior cognizance of their class, standing as humble workmen at the helm and furnace, toiling by day, watching by night, while the force of the stream and the paddles was sweeping their ill-fated bark, freighted with their dying or dead companions, through the manifold dangers of their unknown course. The author of the volume before us was the clear-headed and stout-hearted pilot who did this, the un-

doubted preserver of the ship and her surviving crew; and the slight and simple way in which he speaks of his own exertions strikingly illustrates the old truth, that the brave man is ever modest." (a) Such an action as this of itself claimed the highest testimonial, and I am proud of our Government (I believe I may give Lord John Russell the honour of the deed), that such a testimonial was conferred in the dignified and honourable appointment which you received in Her Majesty's Customs, which you still retain, and which we all wish you to live long to do honour to. Of the more special cause of the present testimonial, your labours in promoting the welfare and dignity of your brother officers on board ship in the navy, I can myself speak from personal knowledge, and can bear witness how warmly, how earnestly, how indefatigably, how long, and how successfully you conducted your noble agitation. And perhaps I am the better qualified to speak of this great triumph, from my having had personal knowledge—now, alas! fifty years since—of the evils which it has now at last remedied. But the best and most satisfactory proof of the value of this measure is afforded by the gratifying fact, that the candidates for Medical appointments in the Navy, since it was carried, have come to be numerous and abundant, while previously the state of things was the very reverse. These statements suffice to prove that the present is no idle ceremony, but that it is a tribute due to you as a benefactor of your brethren and of your country; and I do not doubt that the testimonial will be cherished by your descendants, the bearers of your name—some of whom I see here—long, long, as an heir-loom of honourable distinction. I am sure, in concluding, that I am only conveying the wishes and feelings of all present, and of all who have had a share in the production of this testimonial, when I express an earnest wish that you may be long spared for the good of your country, and the happiness of your amiable family.

#### DR. M'WILLIAM'S REPLY.

SIR JOHN FORBES.—I wish I had the power to give expression in a suitable manner to even a small part of what I feel at this moment. Never did the truth of the maxim, that "when the heart is most full of emotion, the tongue is then least obedient to its dictates," come home to me so forcibly as on the present occasion. And when I look upon this splendid testimonial—when I call to mind the circumstances under which it is presented—when I think of the man by whom I am thus honoured, I may well be excused if I fail adequately to convey to you my heartfelt thanks and gratitude for so high an appreciation of my humble services. You tell me, Sir, that these superb pieces of plate are presented to me by the Medical officers of the Royal Navy, in consideration of services which I have rendered in the cause of Naval Medical Reform; and this leads me, with your permission, to say a few words with reference to the efforts that were made in that direction, to the circumstances that influenced me in making them, and to those men without whose support and encouragement all efforts must have proved wholly unavailing. When I first entered the Naval service, nearly thirty years ago, I found prevailing among the Medical officers, more especially among the junior class, a very general dissatisfaction—a degree of dissatisfaction, indeed, which could not fail to be prejudicial to the interests of the public service. The Assistant-Surgeons complained, and they complained justly, that their position on board ship was not such as that to which they were entitled by their rank, their profession, the authority of an order in Council, and other claims. Respectful memorial, petition, and urgent remonstrance, although emanating from various and influential sources, long proved unavailing to produce the slightest concession to the claims of the Naval Medical officers; and it was not until the sitting of a Commission to inquire into naval and military promotion and retirement, in 1839-40, that a bright spot appeared through the heavy cloud that hung over the prospects of the department. The Commissioners instituted the inspectorial rank in the service, and conferred other benefits upon the Medical officers, by which they became entitled to the gratitude and thanks of the whole department. They recommended the assimilation of the Naval Medical officers in rank and in title with the officers of the Army Medical Department; but, as is too well known, the recommendation has never been properly carried out, as to this hour the naval

inspectorial grade are assigned a rank inferior to that of their brethren in the sister service. This ought not to be, and surely cannot much longer be allowed to exist. As to the Assistant-Surgeons, the Commissioners never questioned the propriety or expediency of admitting them to ward-room privileges, but they could not see their way by which the desirable improvement could be effected. In their report they stated that, "There were practical difficulties in the way of making any arrangement which could accomplish this in a satisfactory and uniform manner in all classes of ships." Some time in the year 1846, I learnt from various sources that the grievances of the Assistant-Surgeons had again been much talked of on the foreign as well as on the home naval stations. I ascertained that on one of those stations certain men, pre-eminent in the fleet and in the service for their talents and judgment, as well as for their attachment in other respects to the service—men whose general and professional character placed them far beyond the suspicion of being actuated by the love of notoriety, or of agitating for mere agitation-sake,—had felt their position so keenly, that they had resolved to leave the Service unless redress were obtained. As types of the class of men of whom I am speaking, I may mention, as then on a foreign station, Dr. Fred. James Brown, now the Consulting Physician and Surgeon of Chatham; and at the time I speak of as attached to the Home station Dr. Andrew Clark, now one of the Physicians of the London Hospital, and distinguished not only as an accomplished Physician, but as a diligent, able, and successful original inquirer. Any one at all conversant with the Service, and interested in its welfare, could not fail to perceive the amount of danger and injury impending over the Medical department by the prevalence of discontent among such a class of men. I therefore felt it a duty, in reply to some statements made by a Lord of the Admiralty in the House of Commons, which appeared to me to be erroneous, and calculated much to add to the existing dissatisfaction, to address a letter, with my name appended, to the editor of the *Morning Herald*, in which I stated respectfully, and I believe in words free from offence to any one, my views of the whole question. I have good reason to know that the views then taken by me were in harmony with those of every Medical officer in the service, and they have never, so far as I am aware, been impugned by any officer of the other branches of the service. I conscientiously can declare that I was working, as I conceived, for the public good, and that my sole object was to prevent the ruin of the Naval Medical Department, which I then considered imminent. I need not dwell upon the various events that preceded the attainment of the great object as regarded the Assistant-Surgeons; but I cannot pass over in silence the uniform and constant support of all my brethren in the service; the sympathy of the Colleges and Professional Corporate bodies of the United Kingdom, and of the whole of the Profession in civil life; the steady and efficacious representation and support of the general and professional Press; and the powerful, unflinching, and effective advocacy of the cause by Boldero, Hume, Wakley, and others, in the House of Commons; and by Lord Brougham, Lord Campbell, the Duke of Richmond, and others, in the House of Lords. The justice of the cause of the Assistant-Surgeons was at length recognised by the Admiralty, who in a circular of July 16, 1855, ordered, "that Assistant-Surgeons of the Navy were to take relative rank with Lieutenants and Assistant-Surgeons of the army, and to mess in the ward-room."

I need not allude to the complaints, the heart-burnings, the disappointments, to say nothing of the injury and loss to the Service that might have been averted, had the Order in Council, obtained by Lord Melville in 1806, been fully carried out in proper time. How strange and inconsistent does it now appear that successive Boards of Admiralty, who could equip and send forth the finest fleets the world ever saw, were so long incapable of seeing, or unwilling to see, the only means by which the Naval Medical Department could be efficiently recruited, and thus preserved from ruin. I say efficiently recruited, because, as is too well known, until of late years the candidate list was always at zero. What is its condition now? Sir John Liddell, who, as everybody knows, has during his whole life been devoted to the service, informed me not long ago that he had candidates enough and to spare. I must own that I look forward with much hope to the prospects of the Naval Medical service.

(a) Brit. and For. Med. Rev. vol. xvi. p. 259.

Sir Charles Wood has already earned a title to the grateful thanks of the whole department by his conduct to the Assistant-Surgeons; the present senior Naval Lord, Sir Richard Dundas, is a man of high honour, and of inflexible integrity and justice, and he cannot be insensible to the claims of his illustrious grandfather, to the everlasting gratitude of the Naval Medical officers, and to the hereditary reputation which he has thereby to sustain. Sir John Liddell, as you are well aware, has ever, whether at Malta, at Haslar, at Greenwich, and as Director-General, been the warm friend of the Medical officer. From such men we may reasonably expect, that all anomalies and defects in the department will speedily be remedied. I must now conclude. To all who have contributed to this magnificent gift (destined I trust never to leave those of my family who may follow me) I would desire to offer my hearty and sincere thanks. To the Committee, and especially to the Secretaries, my profound gratitude is also due. You, Sir John, as the organ of the Committee, in the address with which you have honoured me, have been pleased to represent my career and merits in the Service in too exalted colours. You have applied language to me flattering and complimentary, far beyond my deserts, but nevertheless I cannot help being gratified by what you have said. I feel that your whole course of life is against the supposition that you could utter that which you did not really believe, and I rejoice to be thought well of by you. I repudiate all insensibility to the gratification of being told that I have in any measure deserved well of my fellows, and I feel assured you will acquit me of affectation when I add—

"*Lectus sum laudari a viro laudato.*"

## MEDICAL NEWS.

**APOTHECARIES' HALL.**—Names of gentlemen who passed their examination in the Science and Practice of Medicine, and received Certificates to Practise, on Jan. 28:—

BACON, GEORGE MACKENZIE, Lewes, Sussex.

CHEVES, ALEXANDER BRUCE, Aberdeen.

DUCHESNE, ROBERT, London.

GRAY, EDWARD BENJAMIN, Oxford.

LAWRENCE, ARTHUR GARNONS, Carmarthen, S.W.

WALKER, HENRY, Lynn, Norfolk.

As an Assistant—

MILSON, RICHARD HENRY, St. Mary's Hospital.

## DEATHS.

ALDERSON.—Jan. 28, at Wakefield, John Septimus Alderson, Medical Superintendent of the West Riding Asylum, (York). M.R.C.S. and L.S.A., 1839.

BROWN.—Jan. 11, at Constantinople, George Barron Brown, M.D., of Bolon, Anatolia, Asia Minor.

CAMPBELL.—On the 19th January, William Wilson Campbell, M.D., J.P., at his residence, the Castle, Portstewart, after a short illness.

CAMPBELL.—Jan. 28, Donald Campbell, Hon. E. I. Company's Service.

ELLIS.—Jan. 28, at Colston-parade, Bristol, Robert Ellis, L.R.C.S., Edin. 1831. Aged 50.

MOORE.—On the 30th November last, murdered within twenty miles of Jubbulpore Station, Presidency of Bengal, Dr. Thomas Moore, late 63rd N.I., aged 37 years, fifth son of the late George Moore, Esq. of Dublin.

RAWES.—Mr. R. L. Rawes, Secretary of the Royal College of Physicians, died on the 1st inst. Though not a Physician, Mr. Rawes has been for so many years so intimately associated with Physicians, and has been so much liked and so highly esteemed by them, that his loss is sincerely regretted by a very large body of the Profession.

UNIVERSITY OF OXFORD.—The form of statute uniting the Aldrichian Professorship of Medicine with the Regius Professorship has been read and promulgated.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL.—Only one death occurred here last year among 250 patients.

DR. LIVINGSTONE.—The Queen has been graciously pleased to appoint David Livingstone, Esq., the celebrated African traveller, to be her Majesty's Consul in the district of Quillimane, Senna, and Tite, on the eastern coast of Africa.

THE RELIEVED FROM LUCKNOW.—The following names appear in the list of arrivals from Lucknow to the Fort of Allahabad, Dec. 11th.—Mrs. Bartram, widow of Dr. Bartram, Bengal Army, and 1 child. Mrs. Brydon, surgeon, B. A., and 2 children. Mrs. Wells, wife of Assistant-Surgeon, B. A., with 1 child. Mr. and Mrs. Kindall, Assistant-Surgeon, B. A. Mrs. Pitt, Assistant-Surgeon, B. A., with 1 child. Assistant-Surgeon, T. Carey, H. N., 64th regiment, wounded between 29th Nov. and 2nd Dec.

INCREASE OF POPULATION.—According to the last quarterly report of the Registrar-General, "as the births amounted to 160,975, and the deaths to 110,697, the natural increase of the population in the last three months of 1857, was 50,278 in 92 days, or 546 daily in England and Wales. The natural increase in the United Kingdom was probably about 800 daily. The excess of births over deaths, and therefore the natural increase of the population of England and Wales, was 242,866 in the year 1857, or about 666 daily. In the United Kingdom the natural increase probably did not exceed 1000 daily."

MEDICINE AT CAWNPORE.—A correspondent says, "To notice the devotion and exemplary conduct of our medical staff would exceed my abilities. To them I trust the official report will do ample justice, for they have laboured unceasingly in their trying vocation, and unceasingly devoted themselves to their painful duties. I have heard grey-haired campaigners frequently remark that no annals of any military operations will rival those of our late siege in the frightful character of wounds, and the unusual number of cases requiring immediate amputation; and if it be borne in mind that the high-tiled roof of our General Hospital was the only mark open to the enemy, by reason of which all their guns and mortars were directed to it, it will be evident that our medical officers had to discharge their duties under circumstances of difficulty and danger. If we had a Brigade-Major or a Quartermaster-General to ~~the establishment~~ the state of affairs and confusion ruling from first to last, the utter absence of every necessary arrangement for the order and well-being of all within, and for the cleanliness of our garrison, would argue those officials to have been simply myths. That sickness has not broken out among and decimated us is attributable to a merciful Providence and the season of the year."

MARRIAGES OF CONSANGUINITY.—The Committee of the American Medical Association on Influence of Marriages of Consanguinity upon Offspring solicits the aid of the Medical Profession throughout the Union in collecting facts upon this interesting subject. The points of information more particularly desired are, 1st. The degree of consanguinity of the parties, and whether by the father's or mother's side (as first, second, third, or fourth cousins, or more rarely, uncle and niece or brother and sister). 2nd. The approximate date of marriage (this is only requisite to show whether the fruitful period is passed, and the case complete in its results.) 3rd. The constitutional diathesis and temperament of each parent, their occupation, and such habits or circumstance as are, in the opinion of the observer, calculated to influence the normal development of offspring. (Where the parties are personally known to the contributor, the Committee requests that the colour of the hair, eyes, and complexion may be noted.) 4th. The number, sex, and condition of the children produced by each marriage. 5th. The number and sex of the children who have died young, their ages at death, and causes when known. The Committee desires to accumulate a mass of statistical truths, whose aggregate will determine beyond question whether marriages of consanguinity are in the main prejudicial to the offspring; and it begs the contributors to report the instances of such marriages within their various circles of observation, without selection, whether followed by well-developed or imperfect issue; or by sterility. Any of our readers interested in the matter may communicate with the Reporter, Dr. Beemiss, Louisville, Kentucky, until the 1st of April next.

**FORMULE FOR SESQUICHLORIDE OF IRON.**—Dr. Vicente recommends as a local hæmostatic, aq. dest. 100, sesqu. ferri 3 to 5 parts. As an internal hæmostatic: sesquich. ferri 1, aq. dest. 500 parts. A spoonful of this is to be taken every hour, or oftener, according to the case. The same formula is usefully employed as an injection in uterine hæmorrhage, and as an enema in chronic or choleric diarrhœa. The following hæmostatic and resolvent ointment has been employed by the author in old lardaceous ulcers, white swelling, chronic and acute rheumatism, chronic ulceration of the scalp, and poly-pous, warty, or condylomatous excrescences of the anus, etc.: Axung. 30, sesquich. ferri 4 to 15 parts.—*Revue Méd.* Dec. p. 764.

**COLD WATER IN DYSENTERY.**—Dr. Hiard states, that for several years, during which he has pursued the following treatment, he has hardly ever met with a fatal termination in even very bad cases of dysentery, the patient being usually completely restored within two or three days, and sometimes sooner. On the first visit he is directed to drink glass after glass of cold water until three or four quarts have been taken. The pain soon ceases, and the stools become rare. Next day, the water is continued, and as a precaution against reaction venesection is performed, the dysentery usually ceasing. To encourage a slight transpiration the cold water is replaced by tepid rice water, sharpened with vinegar. In some rare cases the disease resists till the sixth or seventh day, and then on the eighth a blister is applied to the leg, and sometimes another bleeding is employed. Enemata and opiates are both forbidden.—*Revue Méd.* December, p. 753.

## VITAL STATISTICS OF LONDON.

Week ending Saturday, January 30, 1858.

### BIRTHS.

Births of Boys, 880; Girls, 870; Total, 1750.  
Average of 10 corresponding weeks, 1848-57, 1611.

## TO CORRESPONDENTS.

*Impatient.*—Mr. Huxley's lectures will not be continued.

*Mr. Sansom.*—Notices of subjects for discussion at the Societies should be sent not later than the Wednesday before publication.

*Dr. Seward.*—Dr. Jenner's lectures are always printed immediately after they are received from the lecturer.

*Mr. Musket's* case will appear before the end of the month.

*Dr. Savage's* Clinical Experience on Uterine Deviations will appear next week, with several illustrations.

*Dr. Moriarty.*—Book and subscription received.

*A Subscriber.*—The fee should be divided.

*Mr. Newman's* case shall appear.

*Philanthropos.*—There can be no doubt that confirmed drunkards might be placed under restraint for a time as lunatics, with great advantage to themselves and the community. But an Act of Parliament must be passed before it can be done.

*Mr. Jackson's* case of Laceration of the Diaphragm shall appear.

*Vigil.*—We do not wish to say anything of the individual referred to, but we may say in general terms, Avoid all advertising aurists.

*Dr. J. F. Churchill* has written to us, objecting to his name being mentioned as the proposer of a secret remedy; but there is nothing in his letter to alter the opinion we expressed in our review of his book.

**ERRATUM.**—In the 2nd paragraph of Dr. Bond's communication in our last Number, p. 126, for *Dr. Halford* read *Dr. Hamernik*.

MR. SYME AND HIS COLLEAGUES.

In a letter to us this week Dr. Renton says—  
"In presence of a member of the College Committee, the clerk told me this morning, when I called upon him, that on permission being given to withdraw the letter, he handed it over to Dr. Christison, who unconditionally received it. On being asked if it was returned with reference to retraction or correction, he answered, *Certainly not*, for he considered the letter was altogether withdrawn, and therefore no notice of it was taken in the minutes of the Committee. On inspection of the City Record, I found that it contained no reference to Dr. Christison's letter." Dr. Renton adds,—"With reference to Mr. Syme's worthless innuendo as to my 'position,' I may show up his own peculiar position in a late important surgical operation, so far as the case bears on Pathological Science and Clinical Teaching."

COMMUNICATIONS have been received from—

Dr. TODD; Mr. PAGET; Dr. CONOLLY; Dr. WILKS; Dr. RIGBY; Mr. WHITE COOPER; Dr. SAVAGE; Dr. RICHARDSON; Dr. ELLIOT, Carlisle; Dr. HALFORD; Dr. BUTLER, Burlington, New Jersey; Dr. GORDON HARE; Dr. BOND; Dr. GRIFFIN, Bristol; Mr. TERRET; Mr. REED; Mr. WIGLES-WORTH; Mr. GODFREY; Mr. NEWMAN; Mr. WHEATLEY; Mr. M'DERMOTT; PHILANTHROPOS; Mr. STOKES; Mr. VINCENT JACKSON; VIGIL; Mr. RIVERS; Dr. SEWARD; Mr. SANSON; Mr. PITTARD; Dr. GOULD; Dr. CAMPS; Mr. W. SANKEY; Mr. D. THOMSON; Mr. H. GREER; Mr. C. SPENCER; Dr. J. BRENNER; Mr. E. DAVIES; Mr. W. CAIR; Mr. N. CRIEF; Dr. DALGLISH; Mr. J. HILL; Mr. A. T. THOMSON.

## APPOINTMENTS FOR THE WEEK.

Feb. 6, Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's, 2 p.m. Charing Cross, 1 p.m.  
ROYAL INSTITUTION, 3 p.m.: Professor Bloxam, "On the Chemistry of the Elements which circulate in Nature."  
MEDICAL SOCIETY OF LONDON, 8 p.m.: Mr. R. Dunn, "On Mental Physiology, or the Correlations of Physiology and Psychology."  
GUY'S PHYSICAL SOCIETY, 7 p.m.: Mr. Fagge, "On Pneumonia."

### 8. Monday.

Operations at the Royal Free Hospital, 1 p.m.; Metropolitan Free Hospital, 2 p.m.; Orthopaedic Hospital, 8 p.m.

### 9. Tuesday.

Operations at Guy's, 1 p.m. Westminster, 2 p.m.  
ROYAL INSTITUTION, 3 p.m.: Professor Huxley, "On Animals and Plants considered Morphologically."  
ZOOLOGICAL SOCIETY, 9 p.m.  
ROYAL MEDICAL AND CHIRURGICAL SOCIETY, 8½ p.m.: Mr. Hutchinson, "On a Case of Bronzing of the Skin." Dr. Mackenzie, "On the Action of Galvanism on the Contractile Structure of the Gravid Uterus."

### 10. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m. Orthopaedic Hospital, 8 p.m.  
MICROSCOPICAL SOCIETY, 8 p.m.  
NORTH LONDON MEDICAL SOCIETY, 7 p.m.: (Annual Meeting.)

### 11. Thursday.

Operations at St. George's, 1 p.m.; Middlesex, 12½ p.m.; Central London Ophthalmic, 1 p.m.; London, 1½ p.m.  
ROYAL SOCIETY, 8½ p.m.  
ROYAL INSTITUTION, 3 p.m.: Professor Tyndall, "On Heat."

### 12. Friday.

Operations at the Moorfields Ophthalmic, 10 a.m.; Westminster Ophthalmic, 1½ p.m.; Great Northern, 2½ p.m.  
ROYAL INSTITUTION, 8½ p.m.: Professor Faraday, "On Static Induction."

## EXPECTED OPERATIONS.

King's College Hospital.—The following operations are expected at this Hospital to-day (Saturday), at 2 o'clock:—  
Prolapsus uteri; necrosis of femur; urinary fistula; fistula in ano; epithelial cancer from face(?).

## City of London Truss Society, 76,

QUEEN-STREET, CHEAPSIDE.—A Vacancy having occurred in the Office of Surgeon to this Institution by the lamented death of JOHN C. TAUNTON, Esq., persons desirous of offering themselves as Candidates for the Situation are requested to send in their written Testimonials, addressed to the Secretary, on or before Monday the 15th inst., at 12 o'clock at noon; after which day no applications will be received. No person shall be admitted a Candidate until written Testimonials concerning him are produced to the Committee and approved of by them. According to the Rules of the Society, "No person shall be admitted a Candidate for the Office of Surgeon who is not a Member of the Royal College of Surgeons of London, nor any person who practises Pharmacy or Midwifery, or is interested in the Sale of any Advertised Medicine; and he shall be disqualified for his Office of Surgeon to this Charity if at any time after his Election he shall engage in any of the above branches, or enter into a partnership with any person so engaged."

Further particulars may be verbally obtained of the Secretary, at the Institution, on Saturday the 6th, and Wednesday the 10th inst., between the hours of 12 and 1 o'clock at noon; also on Friday evening, the 12th inst., from 6 to 8 o'clock.

Feb. 1st, 1858.

THOS. EGLINTON, Secretary.

## Glycerine.—An Impure Glycerine is

now being sold on the statement that it is as pure as the Patent Distilled Glycerine of Price's Patent Candle Company. The Company beg the application of the following simple tests:—For unpleasant smell, rub a few drops over the back of your hand, when the fetid mouse smell will, if present, at once come out. For lead and other metallic impurities, test by a current of sulphuretted hydrogen. For lime and other earthy impurities, test by oxalate of ammonia or chloride of barium. The Company are not responsible for any Glycerine except that sold in bottles having capsules lettered "Price's Patent." Price's Patent Candle Company, Limited, Belmont, Vauxhall, London.

## Huxley's Spiral Abdominal Belt

is constructed on a principle which secures the required support, without being liable to displacement, the fault which has hitherto characterised these appliances. When required, they are fitted with Air-pads for Umbilical, Inguinal, and Femoral Hernia; also with a longitudinal Air-pad for the support of the lower part of the Abdomen, and band with Air-pad for Prolapse Uteri and Prolapse Ani. These goods, in addition to Stockings, Thigh-pieces, Knee-caps, etc., supplied 30 per cent. lower than the prices hitherto charged, every article being of the very best quality.

Measures required—circumference at a, b and c; depth from a to c.

Priced and Illustrated Catalogues on application to E. HUXLEY, 8, Old Cavendish-street, Oxford-street, W.

## Great Saving in the Purchase of Six

GROSS OF NEW MEDICAL GLASS BOTTLES and PHIALS assorted to suit the convenience of Purchasers, at ISAACS & SON, Medical Glass Bottle Manufacturers.—London Warehouse, 6, Warren-street, Tottenham-court-road.

	s.	d.
6 and 8 oz., any shape, plain, or graduated ..	8	0 per gross.
3 and 4 oz., ditto ..	7	6 do.
1 oz. Moulded Phials ..	4	6 do.
1 oz. ditto ..	5	6 do.
1½ oz. ditto ..	6	0 do.
2 oz. ditto ..	7	0 do.

No remittance required until the goods are received. Packages free. Delivered free within seven miles. Immediate attention to country orders. Post-office Orders payable to S. Isaacs and Son, at the Post-office, Tottenham-court-road, London. Bankers: Unity Bank.

## Great Reduction in the Prices of New

MEDICAL GLASS BOTTLES and PHIALS, at the ISLINGTON GLASS BOTTLE WORKS, ISLINGTON-PLACE, PARK-ROAD.

Warehouse—3, UPPER COPENHAGEN-STREET, BARNSBURY-ROAD, ISLINGTON, LONDON, N.

E. and H. HARRIS beg to submit the following prices for quantities of not less than 6 gross, assorted to suit the convenience of the purchaser.

	8s. per gross.
6 & 8 oz., any shape, plain or graduated ..	8s. per gross.
3 & 4 oz., do. ..	7s. 6d. do.
1 oz. white moulded phials ..	4s. 6d. do.
1 oz. do. ..	5s. 6d. do.
1½ oz. do. ..	6s. do.
2 oz. do. ..	7s. do.

No remittance required until the goods are received. Packages free. Delivered free within 7 miles. Immediate attention to country orders. Post-office orders, made payable to E. and H. HARRIS, at the Chief Office, London.

Bankers: Union Bank of London.

## The Medicated Cod Liver Oils,

comprising

OLEUM MORRHUÆ CUM QUINA.

OLEUM MORRHUÆ CUM FERRI IODIDO.

&amp;c. &amp;c. &amp;c.

Prepared only by SAVORY and MOORE, 143, New Bond-street.

## Liquor Pepsinæ.—A Convenient and

efficacious preparation by  
SAVORY and MOORE, 143, New Bond-street.

## Wines from South Africa.—Port,

SHERRY, etc., TWENTY SHILLINGS PER DOZEN. These Wines, the produce of a British colony, which has escaped the vine disease (the vintage occurring in February may account for the same), are in consequence wholesome, and are warranted free from acidity and brandy, are admitted by Her Majesty's Customs at half-duty, hence the low prices. A Pint Sample Bottle of each for twenty-four stamps, Bottles included. Packages allowed for when returned.

"We have taken the trouble to try Mr. Denman's wines, and have also submitted them to several of the clergy, and the opinion formed is that they are worthy of being patronized."—Clerical Journal, October 22, 1857.

EXCELSIOR BRANDY, Pale or Brown, 15s. per gallon, or 30s. per dozen. Terms—Cash. Country orders must contain a remittance. Cheques to be crossed "Bank of London."

J. L. Denman, Wine and Spirit Importer, 65, Fenchurch-street. Counting-house entrance, first door on the left up Railway-place.

## Wines from the Cape of Good Hope.—

PORT, SHERRY, MARSA, MADEIRA, BUCCELLAS, &c., all at 20s. per Dozen—pure and wholesome Wines, free from acidity and brandy, the produce of vineyards at the Cape of Good Hope, where the vines of Portugal and Spain are now being carefully cultivated, and have escaped the disease. Her Majesty's Government allows these Wines to be imported at half the duty, hence the low price of 20s. per dozen. Samples of any two qualities sent on receipt of twelve stamps.

THE UNIVERSAL BRANDY, 15s. per Gallon, or 30s. per dozen. "That wine, equal to any ever produced, can be made at the Cape, all the world has acknowledged."—Times, Nov. 8th, 1856.

W. and A. GILBEY, Wine Importers, Brandy Distillers, &c., 357, Oxford-street, London, W.; three doors west of the Pantheon. Cheques to be crossed to our Bankers, the Bank of England.

## Electro-Chemical Bath to be Sold, a

Bargain, consisting of a Large Copper Bath, powerful Galvanic Battery by Smee, and insulating frame. Also, a quantity of sulphuric acid, lead piping, conductors, etc. Cost £19, may be purchased for half that amount. Apply to H. S. Fiddes, 5, Deptford-bridge, Deptford.

## Retreat for Ladies Mentally afflicted.

EARL'S-COURT HOUSE.—This first-class Asylum for the reception of ladies only is situated at Old Brompton, the healthiest suburb of London, surrounded by six acres of ornamental grounds. Terms, regulated by the accommodation required, can be had on application or forwarded by post, with the highest testimonials from the leading members of the Medical Profession.

## For Use Medicinally, in all Diseases of

the STOMACH, CHEST, etc., for dressing and deodorising cancer and all foul wounds, for purifying sick chambers, for embalmment of the dead, etc., MR. JAMES ROBERTSON'S PATENT CARBONIZED PEAT MOSS. The various kinds of powder and lozenges are prepared solely by the Health of Towns Improvement Company. Sole Wholesale Agent Joseph G. Thompson, Esq., 2, Adelaide-place, London-bridge, London, E.C. and 5, Donegal-square, Belfast; sold by Mr. W. L. Bird, Pharmaceutical Chemist, 42, Castle-street, East, Oxford-street, W.; Mr. J. Johnson Chemist, 128, Upper-street, Islington, N., London; Messrs. Bewley and Evans, Dublin; and all respectable Chemists. See extracts from publications on the subject, with the preparations.

### PURE SPIRITS FOR THE FACULTY.

By a small annual payment, Life Assurance secures the following provisions:—

1. Policies at death of husband, father, or son, so that widows and children are not left destitute.
2. Settlements secured in marriage contracts.
3. Endowments to children; so that funds are provided for apprenticeships, &c.
4. Security to creditors to provide against the death of their debtors.
5. Security to the debtors themselves; so that at death their estate or business is unencumbered by debt.
6. Capital to meet the loss entailed by the falling in of annuities or reversions.
7. Funds to meet renewals of leases at increased rents.
8. Sums of money payable to the assured themselves on attaining a certain age.

The attention of the Medical profession is called to the following scale of fees payable by the Company on business introduced by the medical attendant:—

Fee of £2 2s. for every assurance of £250 and upwards.

Fee of £1 1s. for every assurance of £100;

and, in addition, a commission of 10 per cent. on the premium of the first year, and five per cent. on subsequent payments.

Prospectuses and proposal forms may be obtained on application to  
FREDERICK BIGG, Actuary and Secretary.

449, Strand, Charing-cross.

## BROUGHAMS.

# Kinder, M'Naught, and Smith,

MANUFACTURERS, WORCESTER, beg respectfully to invite the attention of professional men to their improved Medical Broughams, as under:—

Width of Seat.	Weight.	Price.
3 ft. 5 in. . . .	7½ cwt. . . .	85 Guineas.
3 ft. 6 in. . . .	8½ cwt. . . .	95 Guineas.
3 ft. 7 in. . . .	9 cwt. . . .	100 Guineas.

The latter, including a segmental front, with seat for third person. These Carriages are constructed, by the aid of machinery, of the best material, are of excellent workmanship, and particularly adapted to the wants of medical men, either in town or country. Drawings and other particulars forwarded on application.

## ORIGINAL LECTURES.

## A COURSE OF CLINICAL LECTURES

ON

## DISEASES OF THE KIDNEY.

BY GEORGE JOHNSON, M.D. F.R.C.P.

Physician to King's College Hospital.

## LECTURE IV.

WHEN I last addressed you on the subject of renal diseases, I gave you the history of a case in which we found that the urine contained numerous small casts, entangling pus-cells (fig. 5, p. 106). Cases of this kind are by no means uncommon, and in the greater number of instances of this form of acute Bright's disease the patients recover as speedily and as completely as when the tube-casts contain only the epithelial cells, which have been thrown from the uriniferous tubes by a process of desquamation. We have lately had another of these cases in the Hospital, and I beg your attention to the main points in this patient's history, as recorded by my clinical clerk, Mr. Morris Tonge:—

Joseph K., aged 71, a messenger in Doctors' Commons, was admitted into No. 4 Ward on the 5th of March, 1857. He has always lived well, and has been accustomed to drink about three pints of porter daily. Since the year 1824 he has been subject to occasional attacks of gout, which during the last few years have recurred about every six months.

Four months ago, towards the end of an attack of gout, dropsical swelling of the legs began, and has continued to the present time. During the last five weeks he has been troubled with cough and shortness of breath.

On his admission, March 5th, the feet, ankles, and legs, were very oedematous, but there was no dropsy of the face. His breath was short, and he had a cough, but he expected little. Large crepitation was heard over the lower part of the lungs behind. The sounds of the heart were normal; his tongue was slightly coated, but he had a good appetite, was not thirsty, and made no complaint of pain.

The urine was pale, acid, its specific gravity 1015, and it contained about one-fourth its bulk of albumen. With regard to the microscopic characters of the urine, I may mention that I saw this patient about a month before his admission into the Hospital, and I found that his urine then deposited a copious cloudy sediment, which was chiefly composed of the small pus-containing casts before mentioned, with numerous scattered pus-cells. When he came into the Hospital we found that the casts had the same character, but with this additional feature, that some of them contained oil-globules.

Looking at the history of this case, we concluded that there was kidney-disease of four months' duration. Then, considering the advanced age of the patient, the extent of dropsy, and the amount of albumen in the urine, our prognosis was very unfavourable; and when, after he had been a short time in the Hospital, we found that while in other respects the urine had not improved, the quantity of oil in the tube-casts had much increased, I told you, as many of you will probably remember, that the kidney appeared to be passing into a state of incurable fatty degeneration, and I thought it very unlikely that the patient would recover. The further progress of the case has shown us that our prognosis was wrong. We took too gloomy a view of the disease, or we under-estimated the natural vigour of this old man's constitution.

We thought it not expedient to reduce his strength by any active measures of depletion, and the following was the plan which we pursued. He was directed to remain in bed, to be dry-cupped on the loins every other night, to take an occasional aperient dose of the common white mixture of the Hospital pharmacopœia, and the following—*R. Tinct. ferri sesquich. ℥x. aquæ ʒjss. ter die.* I find no note of the diet prescribed, but he would probably have at first milk-diet, with beef-tea, and afterwards when the tongue cleaned and the appetite improved, a moderate allowance of meat without beer.

The first indication of improvement was an increased secretion of urine, and a subsidence of the dropsy. During the month of March the average quantity of urine in the 24 hours was about 90 oz., the range being from 48 oz. to 120 oz. The sp. gr. was usually 1010; the albumen meanwhile continued abundant. It was not until the middle of April that the albumen began to diminish, and from this time it steadily decreased until at the date of his discharge from the Hospital on the 20th May, it was present only in "very small quantity."

One circumstance which occurred during the progress of this case is worthy of note. On the 30th March, the urine suddenly fell from 89 ounces in the 24 hours to 48 ounces, and at the same time the patient complained of severe headache, and a feeling of sinking; there was also confusion of thought and some delirium. He had not left his bed, nor had there been any alteration of diet or medicine which would explain this sudden change for the worse in his symptoms. A blister was now applied to the nape of the neck, and he was ordered to take a draught containing ammonia, tincture of henbane and camphor mixture. In the course of a few hours gout made its appearance in the left knee, the urine again became copious, the headache and the delirium then quickly ceased, and we got the explanation of the unpleasant symptoms which for two days had caused us some anxiety.

You will not unfrequently find that in subjects of confirmed gouty habit very alarming symptoms, referable to the head or the chest, will speedily subside simultaneously with an attack of gout in a joint. For instance, I have seen a man suffering with urgent dyspnoea apparently from acute bronchitis; then a mustard poultice on the knee has successfully invited gout to that joint, and after 48 hours a slight cough has been the only vestige of the chest symptoms.

Returning now to our patient; I have before told you that when he left the Hospital on the 20th of May the urine still contained "a very small quantity of albumen." Since his discharge he has, at our request, attended from time to time as an out-patient, and we find that his general health continues good. He has had no return of dropsy, but he suffers occasionally from shortness of breath and cough, for which he takes the *pil. ipecac. c. scillâ*, in ten-grain doses. In the month of June he had a sharp attack of gout, during which the amount of albumen in the urine increased considerably, but again diminished when the gout passed off. The urine, when last examined (January, 1858), was found to contain as much albumen as when coagulated by heat, and nitric acid occupied less than one-twentieth of the liquid. We cannot, therefore, consider that all trace of renal disease has in this case been removed, but the old man has, contrary to our expectation, been so far restored to health, that for months past he has been able to continue his occupation as messenger, and he declares that, with the exception of a slight cough and shortness of breath, when he has been exposed to cold, his health is now as good as it has been for years past.

I purpose now to give you a remarkable illustration of the influence exerted by an impediment to the circulation through the heart and lungs, in the production of congestion of the kidney and albuminous urine. The case occurred some time since, when Dr. Whitford, our present House-Physician, was my clinical clerk, and the account which I am about to give you is an abridgement of his very full and complete history of the case.

Christiana S., aged 52, admitted into No. 7 Ward, on the 14th May, 1856, a native of Devon, but resident in London during the last thirty years; married, and the mother of fourteen children, two of which were born at one time. She has had good health until about a year ago, when she caught cold, and had what she calls bronchitis. Soon after this her legs began to swell; but she continued her work until the beginning of the present year, when she went into St. George's Hospital, and remained there fourteen weeks. When she entered that Hospital she had much dropsical swelling of the face and legs. During her stay there this nearly passed away; but it again increased after her discharge, and she then sought admission here.

There was now (May 15) much oedema of the face and legs; she had shortness of breath and cough, with a scanty viscid expectoration. Large crepitation was heard over both lungs. There was extended dullness on percussion over the heart, and a soft systolic bellows sound was heard near the

lower end of the sternum; the heart's impulse was very feeble, the jugular veins were much distended; the pulse was 90, feeble, and somewhat irregular, but not intermitting. The urine was scanty, sp. gr. 1035, turbid with urates, and contained a large quantity of albumen. The tongue was clean, the appetite bad; weakness was much complained of; she was very drowsy, but sleep was disturbed by dreams. To take ether. chloric.  $\mathfrak{m}\mathfrak{x}\mathfrak{v}$ . mist. acaciæ  $\mathfrak{z}\mathfrak{j}$ . 4tis horis., and pulv. jalapæ c.  $\mathfrak{g}\mathfrak{j}$ . om. m.

Two days afterwards, on the 17th, finding that the bowels had not been freely open, that the urine was extremely scanty, and that she was complaining of headache and increasing drowsiness, I determined to give her elaterium as a hydragogue, and I prescribed a dose of half a grain in a pill with confection of roses. Let me warn you, however, that this is a larger dose than I usually give of this medicine, which, if pure and genuine, is sufficiently active in doses of one-fourth or even one-sixth of a grain.

On the 20th the report is, "She was much purged by the elaterium, and to-day she feels very much better. She has no headache, nor is she drowsy. She has passed a much larger quantity of urine, and it contains much less albumen. There is very little dyspnoea."

She continued to improve in every respect for several days. On the 24th the urine had ceased to be albuminous, and the dropsy was fast disappearing. On the 27th the dropsy was nearly gone; not a trace of albumen remained in the urine; dyspnoea, cough, and morbid lung-sounds had ceased; and the bellows sound before mentioned was no longer audible. Certainly surprising results from a single dose of elaterium—the removal of an extensive dropsical effusion, the freeing of the urine from albumen, and the arrest of an abnormal sound over the heart! Yet all this was undoubtedly effected by the dose in question; and I will presently give you what seems to be the true explanation of the phenomena.

At this stage of her history the patient was so much better that she was up and dressed during great part of the day, and we began to hope that we had effected a complete and permanent cure. This hope, however, was destined to be of but short duration. We endeavoured to support her strength by nourishing diet, wine, and steel, but we soon found that unfavourable symptoms were returning. On the 7th June she complained of a feeling of tightness in the abdomen. On the 10th she had pain in the loins, the urine had become scanty, and was again albuminous, and dropsy was re-appearing in the legs. We now again had recourse to elaterium in the dose of one-third of a grain; it purged her freely, but gave comparatively little relief.

On the 12th June it was thought that the bellows sound had returned, but this was doubtful; on the 24th, however, it was distinctly heard in the same situation as before, near the bottom of the sternum, and the cardiac dullness on percussion was found to extend beneath the lower part of the sternum, and somewhat beyond the right edge of that bone. Meanwhile the urine had become as scanty and albuminous as at the first, the lungs had again become gorged, and the general dropsy had increased. We now in our despair gave a variety of diuretics; but they did no good, and from this time the history is one of a continued passage towards an inevitably fatal result. Without troubling you with unnecessary details, I must remind you of one or two main facts which we observed during the further progress of this very interesting case. The systolic bellows sound was henceforth almost, but not quite constantly, audible in the situation before mentioned. On one occasion, July 19th, it ceased for a time after free purging by a dose of elaterium. The heart's action continued very feeble and rapid, the pulse being usually 120; the jugulars were always distended, and sometimes they visibly pulsed. The urine was always scanty, and highly albuminous, and when examined with the microscope was found to contain the small wax-like fibrinous casts.

She died worn out by dyspnoea and want of sleep on the 28th July.

Many of you will remember that while this patient was living, I repeatedly expressed to you my opinion that we should find dilatation of the right cavities of the heart, and consequent insufficiency of the tricuspid valve; the signs of that condition being dullness on percussion extending to the right edge of the sternum, a bellows sound audible over the lower part of that bone, and lastly distension and occasional pulsation of the jugulars.

On examination after death we found the heart much enlarged, and lying transversely across the chest. The walls of the right auricle were thin, its cavity greatly dilated, and the auriculo-ventricular opening was sufficiently enlarged to allow of four fingers being passed through it as far as half their length. The tricuspid valve was healthy, but obviously insufficient to close the dilated orifice. It was apparent that this portion of the heart exactly corresponded with the point where the bellows sound had been heard during life. The mitral and aortic valves were healthy, with the exception of a trifling atheromatous opacity at the base of the latter. The left ventricle was large, and its walls somewhat thickened. The muscular structure of the heart presented no signs of degeneration discoverable by microscopic examination. The lungs were much gorged, and attached to the walls of the chest by old adhesions.

The kidneys were of natural size, had a smooth, congested, mottled surface, and one contained a very small cyst. In other respects they were healthy.

Now, in conclusion, a few words on the pathology of this case. When the patient first came under our observation I inferred from her own account of her illness that the kidney had been the primary seat of disease, and that the bronchitis which had commenced a year before had been a secondary result of the renal disease. As soon, however, as I found that the effect of the purging by elaterium had been not only to carry off the dropsy, but also to free the urine from albumen, I felt sure that the renal congestion and albuminuria had resulted from some impediment to the flow of blood through the heart and lungs, and I was confirmed in this opinion by observing the symptoms before mentioned, which distinctly pointed to dilatation of the right cavities of the heart, and insufficiency of the tricuspid valve.

It is a question which does not admit of a decisive or satisfactory answer, whether the bronchitis which was the first symptom of illness had, by impeding the pulmonary circulation, induced the dilatation of the right auricle. It scarcely seems probable that such would be the effect upon the walls of an auricle not previously in a state of atrophy and degeneration.

As to the mode in which, upon two occasions, elaterium purged away the bellows sound, the most reasonable suggestion seems to be, that the removal of a large quantity of liquid from all parts of the body so far diminished the engorgement and œdema of the lungs, and thus lessened the strain and pressure upon the right cavities of the heart as to allow of the auriculo-ventricular orifice being nearly, if not entirely closed, and the regurgitant current lessened or quite prevented. Those of you who had not the opportunity of closely observing this case may perhaps be ready to suggest that the bellows sound ceased for a time, because the heart's action had been enfeebled by the operation of the strong purgative; as we sometimes find that an abnormal murmur which is distinctly heard when the heart is beating forcibly under the influence of exercise, becomes quite inaudible when the patient has been for a short time in the sitting or recumbent posture. This explanation, however, is not applicable to our case; for, during the time that the murmur was inaudible after the first dose of elaterium, the patient's general strength, and the power of the heart in particular, were considerably greater than they had been before, or than they were at a later period when the bellows sound was again heard.

The copious secretion of urine which followed the free action of the first dose of elaterium was probably not the result of a direct diuretic influence of this drug upon the kidney, but it was simply due to the fact that the large drain of water from the blood through the mucous membrane of the intestines, relieved the distension of the whole vascular system, and so restored the freedom of the circulation through the kidney as through the other abdominal viscera. You scarcely need to be reminded that the amount of urine secreted will be, *ceteris paribus*, in proportion, not to the quantity of blood which the vessels of the kidney contain, but to the volume of blood which passes through the gland in a given time. We often find that in cases of great dropsical accumulation the operation of paracentesis, or acupuncture or incision of the legs, is followed by a very copious secretion of urine. The explanation of this you will infer from what I have just now said of the hydragogue action of elaterium.

## ORIGINAL COMMUNICATIONS.

CLINICAL EXPERIENCE ON THE NATURE AND TREATMENT OF  
UTERINE DEVIATIONS, MORE ESPECIALLY OF PROLAPSUS.

By HENRY SAVAGE, M.D. Lond.

Senior Physician to the Samaritan Hospital.

My object is to state as briefly as possible the result of some years' personal experience of one of the many severe and refractory disorders peculiar to women;—one forcing itself perhaps more than any other on the attention of the practitioner from the pitiable, repulsive, and wretched state of the unhappy subject of it.

From the time of Hippocrates to within the last thirty years, prolapsus uteri derived no help from surgery, except in the shape of an appliance strictly mechanical, called a pessary, which exists in numberless curious varieties, as it were to show not only the frequency and obstinacy of the affection, but the surprising duration for so many years of its earlier history of the one restrictive idea as to its treatment.

Pessaries, even when they were the only resources for prolapsus uteri, had but an uncomfortable reputation, because, as a rule, they failed when used indiscriminately; but in the right sort of cases, as a rule, they appear to me to succeed, and this, too, in the very cases where the knife has been found to fail, and *vice versa*.

The surgical treatment of prolapsus uteri originated with Dr. Marshall Hall, and Dr. Fricke of Hamburg. The principles of one or both have ever

FIG. 1.

FIG. 2.

since formed the basis of everything done by way of operation.

It is stated in the *Rep. d'Acad. R. de Méd.*, Aug. 11, 1835, that a M. Girardin, as early as 1822, proposed the excision of a part of the vagina as a remedy for prolapsus uteri. Whether so or not, the first suggestion of the kind ever carried out was that recommended by Dr. M. Hall, in 1831, and carried into effect by Dr. Hemming under his superintendence (*L. Med. Gaz.* Nov. 1831).

Dieffenbach (*Medicinisches Zeitung*, 1836) says, in allusion to some cases of prolapsus uteri with mortification of the vagina getting well on the healing of the latter, that he had had frequent opportunities of imitating this natural curative process by removing slips of mucous membrane from the vagina. Velpeau mentions that in 1831 many young French Surgeons, then in Germany, addressed letters to the *Gazette Médicale*, describing an operation performed by Dieffenbach for prolapsus uteri in all respects like Dupuytren's for prolapsus recti. This, if correct, still leaves Marshall Hall's the first recorded case. It will presently be seen that all operations tending to narrow the vaginal canal were in reality varieties of his operation.

All operations tending to close the

vaginal orifice so as merely to prevent the uterus from falling out of the vagina, are modifications of Fricke's method. Dr. Fricke's first operation was performed by himself on the 3rd March, 1832.

The choice of means (Pessary, Hall's, or Fricke's method), and the chances of success in any particular case must obviously turn entirely upon these two questions. What are the natural conditions tending to keep the uterus in its normal situation? And, What is the character of the agency to be counteracted—that by which it is so frequently forced out of place?

The woodcuts on the previous page are reduced from two of a collection of drawings taken at the dissecting-table last spring at Clamart, from an unlimited supply of fresh subjects carefully selected for this and other investigations of the same kind. The broad ligaments are seen as lateral extensions of the fold of peritonæum containing the uterus and appendages. Where its posterior layer is reflected from the cervix and upper part of vagina on each side of the recto-vaginal pouch to line the back part of the pelvis, it is particularly strong, and here, with a trifling traction on the cervix uteri per vaginam, it is thrown into resisting ligamentous folds—cervical ligaments—as is seen in the second cut.

The pelvis having been exposed to view as in the above woodcuts, and its contents not otherwise disturbed, traction was made on the os uteri by means of forceps introduced by the vagina, so as to make the uterus take the ordinary course of a prolapsus. A descent of an inch and a half rendered the cervical ligaments very tense, another half-inch and they began to yield. They were now cut through, and the uterus descended at once another inch. The strain was now found to be sustained by the pelvic peritoneal lining, which yielded slowly onwards towards the broad ligaments, which lastly was only put on the stretch when the uterus was drawn well out of the vulva.

The fair deduction from experiments and dissections of this kind, frequently repeated with great care, appear to me to be as follows:—

1. The uterus under normal circumstances is retained at a certain elevation in the pelvis by special ligaments—cervical ligaments—these ligaments and these only tend to prevent prolapsus.

2. All other kinds of displacements are checked by the broad ligaments, which, however, at all times allow considerable motion backwards and forwards, and to some extent from side to side. As to the natural inclination of the uterus the average is in favour of the direction shown in cut.

3. The weight to be sustained by the perinæum is the resultant of the weight of the floating viscera acted on by the tension of the abdominal muscles, and subject to frequent and variable increase by their contraction—the direction of pressure being determined by the rigid walls of the pelvis in a line crossing the vagina.

4. So long as the cervical ligaments are intact the uterus sustains no superincumbent weight, as from its pear-shape the surrounding viscera tend to press it upwards.

5. The moment the uterus sinks within the inverted vagina the two organs constitute a hollow cone, the uterus at the pendant apex with every mechanical disadvantage. The superincumbent pressure is then a match for any pessary, but that one which will completely do away with the inversion.

6. The vagina does not in the least support the uterus. When not inverted the direction of the superincumbent pressure tends to keep its sides together. In this sense only can it be said to prevent prolapsus; even so, it can have no share in doing this until the uterus has lost the support of its cervical ligaments; on the contrary, it is these ligaments which preserve the elongated position of the vagina, which would otherwise, as it does in fact in prolapsus, shorten into numerous prominent transverse folds.

7. The broad ligament with the uterus in its centre is an unstable and yielding partition, dividing the pelvis into an anterior and posterior pelvic sinus. The small intestines by descending into one or other (generally the latter) become the chief determining cause of the kind of uterine malposition, the broad ligament offering no material check except to the extreme displacement known as anteversion and retroversion.

Prolapsus of the uterus is any degree of malposition tending outwards per vaginam, all other forms are known as Displacements; and this is a distinction sufficiently simple, practical and suggestive. So long as surgical interference

is considered applicable only to cases of complete prolapsus. Pessaries, notwithstanding their questionable reputation, must continue to claim the most serious attention of the practitioner.

But what is uterine displacement if the uterus really have no normal position, no standard locus in the pelvis? Such assertions are obviously absurd if they mean more than that the uterus is very moveable, and is often found within certain limits in various situations without inconvenience to the patient. According to Scanzoni it is disease of the womb itself, and not the displacement, which ever causes annoyance—if so it must be a sort of disease which often disappears, as I can truly say, from long personal experience, from the moment of introducing such a pessary as the patient could wear.

The choice of the pessary is everything. It is impossible to tell what they can do without having abundance of all sorts and sizes at hand to adapt at the moment, or change from day to day until the right one is ascertained; but practice now turns so much on strong prejudice and individual opinion that it is not without misgivings I submit to the Profession the following summary of my experience at the Samaritan Hospital during the last eight years.

The pessary originally was only a medicated ball—a device far too much neglected at the present day. Its use as a remedy for uterine displacement is a later idea, suggestive of the innumerable modifications before mentioned; but the only safe forms after all are the disk and ball with or without a stem. As an active supporting agent the stem must always have some external perineal contrivance, otherwise, stem or no stem, the pessary depends for its efficiency entirely on the vagina, which is an elastic tubular cone, with its apex at the perinæum, seldom found twice alike as to its size, tone, and general condition.

Fig. 3.

If the object be to replace the womb in accordance with the annexed woodcut (Cut 3) representing the normal relation of the parts, then no other contrivance will answer than that known as Simpson's. This pessary is composed of a uterine, vaginal, and pubic portion, fitting into each other at such angles that, when introduced and united, the instrument corresponds with the line of relation indicated. This beautiful contrivance answers perfectly, when the patient can bear it, which, alas, is very seldom, if ever!

The ball pessary, which should never be more than two inches in diameter, ascends when the perineal end of the vaginal cone retains its elasticity, and then it is the best of all pessaries. It removes the uterus out of the line of pressure, and exercises gentle compression upon it, which, particularly when the organ is enlarged, and even tender, is generally highly beneficial. Hollow caoutchouc, or gutta-percha pessaries, perfectly replace the hollow silver pessary, so extolled for its extreme lightness by Professor Meigs. A larger size requires a minor midwifery forceps for their removal, and moreover are not curative, but these decidedly are.

The disk and ring pessaries are intended to stick immovably when they are placed in the vagina, which they render tense, and lengthen it, relatively, to its collapsed and shortened condition, but shorten it absolutely. These pessaries are made of wood, cork, gutta-percha, watch-spring, etc.

The best stem pessary, the only active support, is readily made by fastening firmly a piece of sponge to one end of a piece of gutta-percha tubing of proper length and calibre.

The opposite end has attached to it four slips of elastic vulcanised caoutchouc, which pass up, two before and two behind, to a band round the abdomen, or to the ordinary corsets, when they can be adjusted so as to admit of perfect freedom of motion.

This latter form I have found invaluable in some cases, particularly for temporary use. It never causes annoyance. A small quantity of any injection can be thrown up through the tube to saturate the sponge previously introduced as dry as possible. It can be removed and re-introduced by the patient herself, a difficulty insurmountable in the case of the ordinary disk, which can never be allowed to remain with safety longer than twenty-four hours.

Two years ago Dr. Zwanke of Hamburg sent me a dozen of his pessaries, wherein this objection is entirely done away with.

This most ingenious modification of the disk is best understood by the cuts, (Cuts 4, 5, 6.) It consists of an elliptical disk in two halves joined by a common hinge. A piece of

FIG. 4.

FIG. 5

Original screw.

wire is soldered to each at right angles close to the joint, forming the stem when brought together, and fastened by a simple screw. The screw was found an objection, and I am indebted to a very talented instrument-maker in the neighbourhood of the Hospital, Mr. Russell, for a substitute which renders Zwanke's pessary the most perfect yet devised. It finds its

FIG. 6.

way invariably where it is intended to go; the patient can manage it herself without difficulty. The disk can be covered with any soft material. It steadily retains its place in the vagina, and never fails to keep up the uterus effectually without pain, provided one is selected of suitable size, which is soon determined if there be a few sizes at hand to select from, a condition indispensable to a fair trial of a Zwanke. During the last eight years I have tried myself, or seen tried by others, every kind of pessary I ever heard of, and I have come to the following conclusions:—

As above observed, no pessary but one on the principle of Simpson's can replace the uterus, in the true sense of the

word. The round pessary, the disk and the stem pessary just described, will do all that such inventions are capable of, which is very considerable. An internal displacement of the uterus soon becomes tolerable by the use of a pessary preventing an aggravation of it; the organ eventually becoming a sort of fixture in its new situation, when the pessary can be discontinued. Whenever a round pessary two inches in diameter, or a disk three and a half inches in its longest diameter, is found to fail, then the case is a very proper one for either Marshall Hall's or Fricke's operation.

(To be continued.)

## DRAINAGE AND WATER SUPPLY IN CONNEXION WITH THE PUBLIC HEALTH.

By JOHN SNOW, M.D.

I was visiting a gentleman in the West of England some time ago, and he showed me the plan of the drainage of his house and garden. The drains received the proceeds from the water-closets of the house, and they were made to empty their contents into a brook, which flowed along the lower part of the grounds. I had observed that this brook turned a flour-mill in the estate, about a quarter of a mile lower down the stream, so I inquired whether the miller and his family had any other water for drinking and preparing their food besides that of the brook. The owner of the property replied that they had not. He said he had never thought of that subject, but he would try to get the miller some other water. I do not know whether or not he succeeded; and I have only alluded to the circumstance because it is an instance, on a small scale, of what is occurring nearly all over the country. In very many places the drinking water of the community is polluted by the drainage from water-closets, and the constituted authorities try, with more or less of temporary success, to procure other water.

None of the Water Companies which supply this metropolis have, for the last eighteen months, obtained any water which is polluted by the sewage of the town. Five of these Companies, however, still obtain water from the Thames, in the neighbourhood of Hampton and Thames Ditton, where the river becomes every year more impure, from the contents of the water-closets of houses and villages situated on its banks. It is probable, indeed, that from the subsidence of the water in large reservoirs, and from its filtration, it is incapable of communicating disease; but the inhabitants of London ought not to be satisfied with a probability on this point, they ought to have an absolute certainty that disease cannot be communicated by the water supplied to them. Except for the enormous quantity of water which is required to wash away the contents of water-closets, London would, no doubt, by this time have been entirely supplied with water from springs and wells at a distance, or from deep wells in the chalk formation under the metropolis.

The fact that water-closets cause the pollution of the rivers is not the greatest evil attending them, for rivers can never be entirely free from pollution; a greater evil is that they occasion the demand for such an inordinate quantity of water, that, in most cases, a supply from springs and wells cannot be obtained, and the polluted rivers have to be resorted to for the supply. Croydon and a few other towns of moderate dimensions are indeed supplied with water from deep wells, and Manchester and two or three towns in Scotland are supplied with surface water from extensive uncultivated moors; but a great number of towns are supplied with river water, which is more or less liable to pollution according to the situation at which the water is taken, and which is constantly becoming more impure, from the increasing adoption of water-closets, even in rural districts.

A great part of the water supply of most towns, and almost the entire supply of the rural districts, is derived from pump-wells, which are often very shallow, and are extremely

liable to be polluted. It is my opinion that the absence of drainage, and its defective condition, are injurious to health only by the contamination they cause to pump-wells, or other supplies of water; and that when the health of the community is improved by improved drainage, either in town or country, it is by the amendment which is effected in the drinking water of the locality. I believe also that houses situated on gravel are generally more salubrious than those situated on clay, because organic matters are usually oxidised in passing through the gravel, and converted into mineral substances, chiefly nitrates, which have not the power of communicating disease. It is only when the source of pollution is very close to the pump-well that the gravel does not oxidise the organic matter.

I consider that the ordinary opinion which attributes the illness caused by absence, or imperfection of drainage, to effluvia given off into the air, is altogether a mistake. My reasons for this view of the subject are as follow. In the first place, whenever I have been able to separate the effluvia in question from real causes of disease, I have found an absence of effect. During the cholera year 1854, for instance, the Fleet-ditch was open for a considerable distance, and was covered in during the summer of 1855. The part open in 1854, and previously, passed through portions of the sub-districts of Saffron-hill, of the north sub-district of West London, and of St. James's, Clerkenwell. Now the mortality from cholera, in the Saffron-hill sub-district, was only at the rate of five in 10,000 inhabitants. The mortality in St. James's, Clerkenwell, was only eleven in 10,000; and the mortality in the north sub-district of West London was only five in 10,000, when the deaths in St. Bartholomew's Hospital are deducted.

In 1849 a part of Bermondsey, called Jacob's Island, was surrounded and intersected by ditches as wide as an ordinary canal, and covering several acres. The ditches were usually kept full, and emptied only at intervals. The water of the Thames admitted into them received the sewage of the surrounding population, either directly, from privies which overhung the ditches, or through kennels and drains. A number of the inhabitants of Jacob's Island, and the streets immediately surrounding the ditches, had access to no other water except that of the ditches. They usually allowed it to stand awhile, for a sediment to subside, before they drank it. The Metropolitan Commissioners of Sewers caused an inquiry to be made, at the end of the epidemic of 1849, into the effect of using the water of these ditches; and Mr. John Grant, the Assistant Surveyor to the Commissioners, was kind enough to favour me with the result. In the streets inclosed by the ditches, and immediately surrounding them, there were 7,286 inhabitants. Of these there were 865 individuals having no other supply of water than the ditches, and the remaining 6,421 had the supply of the Southwark and Vauxhall Company, or were supplied by private pumps. During the first nine months of 1849, 18 deaths took place from cholera, and eight deaths from other causes, amongst the 865 persons having no water supply but that of the ditches; and 95 deaths from cholera, and 46 from other causes, amongst the 6,421 persons having another supply. The mortality from cholera was, consequently, at the rate of 208 in 10,000 amongst the persons using ditch water, and 147 in 10,000 amongst the inhabitants who had the supply of the Southwark and Vauxhall Water Company, or that of private pumps. The mortality of the population living amongst and around the ditches, but not drinking the water, was, in fact, almost exactly the same as that of the other inhabitants further removed from the ditches, whilst that of the people who were obliged to drink the water was more than one-third higher, as is shown by the following figures from the report of the Registrar-General. St. James's, Bermondsey, in which Jacob's Island is situated, suffered a mortality from cholera of 142 in 10,000; St. Mary Magdalen, Bermondsey, a mortality of 159 in 10,000, and the Leather Market sub-district of Bermondsey, a mortality of 160 in 10,000. It is proved, therefore, that the population of Jacob's Island did not suffer in their health from the effluvia of the ditches amongst which they lived.

Between the cholera of 1849 and that of 1854, the ditches about Jacob's Island were all filled up, and the late Mr. Chas. Walsh reported that the cholera on that spot was not worse in 1854 than in the surrounding district. Bermondsey suffered more from cholera in 1854 than in 1849, owing to the Thames water, with which it was supplied, having become more impure in the interval. The greatest covering in or

filling up of open sewers or ditches which had taken place anywhere in the Metropolis was in St. James's, Bermondsey; and yet the mortality from cholera in 1854 was 192 in 10,000, being higher than in any other parishes in the south districts of London, except St. Saviour's and St. Olave's, which had the same water supply, and contain also the two large Hospitals.

Mr. Glaisher, in his Report on the Meteorology of London, in relation to the cholera epidemics of 1853 and 1854, expresses his opinion that the disease was increased by the impure exhalations from the river Thames. An examination of the subject in detail does not, however, confirm this opinion. There are seven registration sub-districts situated at the river side, and extending from the sub-district of Charing Cross to that of the south-east sub-district of the City of London inclusive, and every one of these sub-districts had a mortality from cholera, in the epidemic of 1854, considerably below the average of that of the Metropolis. The gross population of these sub-districts was 86,816 in 1851, and the mortality from cholera in 1854 was 203, or 23 in 10,000; that of the entire Metropolis being 45 in 10,000. These seven sub-districts are supplied with water by the New River Company. The sub-districts situated at the river side on the south of the Thames had generally a high mortality from cholera, because they were chiefly supplied with unfiltered water by the Southwark and Vauxhall Company from the river at Battersea; but the sub-district of Lambeth Church, first part, which extends along the river side from Westminster-bridge to Vauxhall-bridge, and was chiefly supplied by the Lambeth Company with water from Thames Ditton, had a mortality from cholera of only 29 in 10,000. It should be observed, also, that districts situated at a good distance from the river had a high mortality, when they were chiefly supplied with water by the Southwark and Vauxhall Company. Thus Walworth, which is from a mile to a mile and a half from the Thames, had a mortality of 131 in 10,000; and Camberwell, more than two miles from the river, had a mortality of 136 in 10,000. Mr. Glaisher tries to explain this high mortality at a distance from the river, by supposing that the exhalations are confined by the neighbouring high grounds; but in another part of his report (p. 23), he has shown that Camberwell is beyond the influence of the Thames and the thick atmosphere of London, and that it enjoys a meteorology similar to that of the country near London. There is no situation in which the exhalations from the Thames would be more liable to be confined by the neighbouring high ground than in the valley of the Fleet river or ditch; and in 1854 this ditch was uncovered for a great distance, and was much more impure than the Thames, yet the districts in its neighbourhood suffered extremely little from cholera, as was before stated.

The fact that persons who work habitually amongst offensive animal substances do not appear to suffer in their health, confirms the view that no material injury arises from the effluvia of sewers and drains. The accompanying table, No. 1, contains the mortality in 1851 amongst persons occupied in certain offensive trades in England and Wales, from the Fourteenth Annual Report of the Registrar-General. These trades comprise the second and third sections of the twelfth class of the Registrar-General, and comprise all the persons working in grease, bones, intestines, skins, hoofs, and horns. The deaths are arranged in decennial periods; and I have taken from the census report of the same year the number of persons living in these trades—both the entire number of 20 years and upwards, and the number living at each decennial period, and have calculated the deaths per thousand for each period of life. I have also done the same for males of all occupations, so as to draw a comparison between the population occupied in offensive trades, and the entire population of grown-up males. It will be observed that in the whole population of males of 20 years and upwards, the mortality was 20 per thousand in 1851, while among persons employed in offensive trades it was only 18.3 per thousand. In other words while the entire adult male population had an average duration of life of 50 years, the average duration of life in the offensive trades was 54 years and seven months. At each decennial period under 45 the proportion of deaths is considerably less in the offensive trades than in the rest of the male population; from 45 to 55 the mortality is precisely the same in both; and at ages above 55 it is slightly higher in the offensive trades.

TABLE I.  
Mortality in Offensive Trades, and amongst Males of all Occupations in England and Wales.

	Aged 20 and upwards			20-25			25-35			35-45			45-55			55-65			65-75			75-85			85 and upwards

(To be continued.)

## THE "SPECIFIC TREATMENT" OF CONSUMPTION.

### NOTES ON THE ACTION OF CERTAIN SALTS OF PHOSPHORUS ON PHTHISIS.

By RICHARD PAYNE COTTON, M.D. F.R.C.P.

Physician to the Hospital for Consumption, &amp;c., Brompton.

In a "Memoir" lately published in Paris (a), and presented to the Imperial Academy of Medicine, Dr. J. F. Churchill has introduced to the Profession, as a "specific" remedy for phthisis, phosphorus in certain combinations. A few months previously he had proposed its employment at the Hospital for Consumption at Brompton; but having then declined to make known its composition, the offer, like many others under similar circumstances, was necessarily rejected by the Medical Board. The new remedy, however, being now no longer a secret, and its efficacy, as stated in Dr. Churchill's work, being so "immediate" and unprecedented, I have thought it a duty to give it a fair trial at the Hospital for Consumption, and to publish the results.

It may be as well to state briefly, that Dr. Churchill is of opinion that the direct cause of tuberculosis is the decrease in the system of the normal proportion of phosphorus in an oxygenizable state, and that the natural remedy should be sought in some compound of phosphorus at the lowest possible degree of oxydation. The hypophosphites appeared to him to offer the nearest approach to such a quality; and of these he selected the hypophosphites of soda and of lime, as being the most soluble and "assimilable." "They produce," he observes (p. 15), "a manifest increase of nervous power, sometimes even from the first day of their administration, together with an unusual feeling of comfort and strength. At the same time the nervous symptoms, if there have been any, disappear, as well as the functional derangement, such as weight, &c., of the intestinal mucous surface. The appetite increases, often in an extraordinary manner. The evacuations become regular, and more abundant; the perspirations, if they have existed, cease; sleep becomes calm and profound." He administered it to thirty-five consumptive patients, all of whom were either in the second or third stage of phthisis. Of these, eleven were completely cured, eleven experienced great melioration, fourteen died, and one was still under treatment.

My experience of this remedy is based upon carefully made observations upon twenty of my own in-patients at the Hospital for Consumption. Copious notes were taken by Dr. Walker and Mr. Ford, the resident clinical assistants; and are open to the inspection of those who may be desirous of obtaining more information than I am able to offer in the present communication. Dr. Churchill's rules for administering it were carefully attended to; five grains dissolved in water, with the addition of a small quantity of syrup, being given three times a-day. The cases consisted of nine males and eleven females, all of whom were adults. Three were in the first stage of consumption, five in the second, and twelve in the third. All were affected with the disease in its simple form, there being no other than the ordinary complications. The remedy was administered for a fortnight, notes being regularly taken at the expiration of this period no improvement was observable, it was discontinued; but if the patients expressed themselves relieved, other medicines were prescribed with the view of testing whether such relief was fairly attributable to "specific" agency, or to other circumstances—such as improved diet, rest, &c., which should always be taken into account in estimating the effect of medicinal agents upon Hospital patients.

Of the three patients in the first stage of the disease, two were not perceptibly influenced by the hypophosphites, but afterwards improved considerably under tonic treatment and cod-liver oil; the other considered himself much stronger, but before admission to the Hospital he had been almost starved, so that good diet, &c. may reasonably claim a fair share of the credit; and he left before other medicines could be tried.

Of the five patients in the second stage of the disease, two were not in any way influenced by the hypophosphites, but

(a) Sur la Cause immédiate, et le Traitement spécifique de la Tuberculose Paris: 1858.

subsequently expressed themselves as feeling "much better" under tonic treatment with cod-liver oil; two slightly improved, but one of these afterwards advanced at a much more rapid rate under steel and oil, and the other seemed to get on quite as well under steel and quinine; the remaining one became much worse from a gradual advance of the malady.

Of the twelve patients in the last stage of the disease, one felt herself better under the hypophosphite than under any other remedy; one improved greatly, but not more than under the subsequent use of other tonics; three improved slightly, but afterwards progressed much more rapidly under steel and cod-liver oil; two were not at all benefited, but found themselves "much better" under a change of treatment; in two cases no effect was observed, and in spite of all treatment, the disease ran on; one of the patients became worse, but subsequently gained strength under the oil and quinine; the remaining two died.

Thus, in only two instances could this remedy be said to act with any marked benefit, and in one of these its good effect was very equivocal, the patient previous to admission having been in an almost starving condition, and leaving the Hospital before the comparative trial could be made with other medicines. In all the rest it acted certainly in no way as a "specific;" in most, it seemed to be inert; and the few cases which slightly improved during its administration were evidently instances of the *post*, and not the *propter hoc*, since some advanced equally, and many of them more rapidly under the subsequent use of steel or quinine with cod-liver oil.

It is very possible that the compound of phosphorus proposed by Dr. Churchill may in some cases have a tonic and beneficial influence; but to any "specific" action upon tuberculosis it seems to have no claim.

In a foot-note to the tabular statement made by the above-named Clinical Assistants, I find the following remarks by Mr. Ford:—"As far as we can judge from these cases, it is obvious that the hypophosphites are of no therapeutic value whatever in the treatment of phthisis; indeed they seem to be simply inert, doing neither good nor harm, except indirectly in the latter sense by interfering with more positively beneficial modes of treatment." This opinion is fully endorsed by Dr. Walker.

The employment of phosphorus in the treatment of phthisis is by no means novel. For the last eight or nine years I have been in the habit of using a mixture consisting of the dilute phosphoric acid with phosphate of iron; and at my suggestion it has been inserted in our Hospital Pharmacopoeia. In many cases much good has attended, and I think I may say been produced by, its administration; but I attribute to it no *specific* action. I believe it is a simple tonic, adapted to certain depressed states of system.

Phosphorus is a well known and apparently necessary constituent of all healthy nerve structure; and in some conditions of low nervous vigour, its medicinal employment may be of very great service. We find that it enters largely into the composition of the most nutritive kinds of grain; and we may be quite sure that it is not placed there without a purpose.

If phosphorus, then, be no specific for phthisis, but a simple tonic acting usefully in certain lowered states of nervous energy, are we to seek further for specific remedies for this most intractable of all diseases? I believe the search will ever be futile. Until we know what *life* really is;—until some new aid can be brought to bear upon its demonstration;—until we find out in what consists that diminished power of vitalizing new products, as exhibited in the formation of tubercle and other imperfectly organised substances from the blood, we must be content with treating consumption, as at present, with tonics and cod-liver oil.

46, Clarges-street, Piccadilly, Feb. 1858

**EPIDEMIOLOGICAL SOCIETY.**—A deputation of the Epidemiological Society waited upon Lord Palmerston, at his residence in Piccadilly, on Wednesday, the 10th instant. The object of the deputation was to urge on the Government the importance of early legislation on the subject of Vaccination. The deputation consisted of Dr. Babington, F.R.S., President of the Society, Dr. McWilliam, F.R.S., Hon.-Secretary, Dr. Waller Lewis, Dr. Seaton, Dr. W. Camps, and Mr. Marson.

## DISSECTION OF AN EYE AFFECTED WITH ENCEPHALOID DISEASE.

By T. WHARTON JONES, F.R.S.

Professor of Ophthalmic Medicine and Surgery in University College, London; Ophthalmic Surgeon to the Hospital, etc.

I am indebted to my friend and former pupil, Mr. Charles Drysdale, for the eye of which I here record the dissection. Mr. Drysdale's friend, Dr. Richardson of Battersea, who attended the case for a few days before death, and made the post-mortem examination, states that the patient was a child two years old; and that one year since, it was seen by two ophthalmic Surgeons in London, who pronounced the disease to be incipient fungus hæmatodes, and wished to remove the eyeball.

Dr. Richardson found the eye prominent, and commencing to separate the eyelids. A bright metallic appearance was observable behind the cornea, and a substance apparently protruding through the dilated pupil. The child was occasionally delirious and convulsed: the bowels obstinately constipated.

*Section cadaveris* forty-eight hours after death.—Dura mater adherent to the calvarium;—encephaloid masses under the arachnoid at intervals; optic nerve of affected eye surrounded by encephaloid enlargement up to the commissure, but all softened and unfit for removal.

The eyeball was of natural size. The structures around it healthy. The cornea was reddish-yellow, looking from the presence, as was found on dissection, of a puro-lymph looking matter in the anterior chamber.

Having dissected away the muscles, etc., from around the eyeball, I divided and reflected the sclerotics on one side, thereby exposing the choroid.

Tracing the choroid forwards, I found it, and the ciliary body, whitish and much thickened.

The cornea, which was next cut into from the same side, and a portion of it reflected, was found transparent, but much thinned.

The anterior chamber,—diminished in its antero-posterior depth in consequence of the iris being pressed forward by the morbid formation, to be noticed below, occupying the place of the vitreous body,—contained the reddish puro-lymph matter above-mentioned. This having been removed, the anterior surface of the iris was exposed.

Through the pupil, which was somewhat dilated, the opaque crystalline projected.

The choroid being next traced backward, was found, in the region of the entrance of the optic nerve, enormously thickened, and of an appearance something like firm white medullary substance which has been hardened in alcohol. This portion of the choroid was intimately incorporated with the sclerotics externally, but internally it was smooth, free and prominent.

The whole interior of the eyeball, naturally occupied by the retina and vitreous body, was filled with a lobulated mass of encephaloid, here pinkish, there brownish or blackish in tint.

Springing from the place of entrance of the optic nerve, and lying on the inner surface of the much thickened choroid above described, there was a shreddy membranous substance with pigment cells on its surface next the choroid. This, which I considered to be a remains of the retina, was lost anteriorly in the mass of encephaloid, just mentioned as filling the whole interior of the posterior segment of the eyeball.

Under the white and thickened ciliary body, the ciliary zone was found still distinct, but also thickened and deformed.

The iris having been cut through and detached on one side, the posterior chamber was laid open and found to contain matter similar to that in the anterior chamber.

The opaque crystalline lens with its capsule preserved its natural position in respect to the thickened ciliary zone, but, as above-mentioned, was much pushed towards the cornea by the encephaloid mass behind.

Having completed the preceding examination, I made a longitudinal section of the optic nerve, running into the eyeball. From this it was seen that the sclero-meningeal sheath of the optic nerve was closely adherent by its inner surface to a morbid mass continuous with, and similar to, the thickened and degenerated choroid, with which the sclerotics, as above-

mentioned, was in a similar manner intimately incorporated. The proper fibrils of the optic nerve no longer existed, but there were the remains of their neurolemmata, tinged of a bright gamboge yellow colour.

Near its entrance into the eyeball, the optic nerve presented a small nodule on one side, but with this exception was not enlarged, though degenerated in structure as above described.

Examined under the microscope, the encephaloid mass, filling the whole interior of the posterior segment of the eyeball, and encroaching on the anterior segment, was observed to consist of colourless cells in various stages of development, some caudate, about 1-2500th of an inch in diameter, and some pigment cells very much larger, together with a granular matter. There were also traces of a fibrous stroma.

The white and thickened portions of choroid, the ciliary body, and ciliary zone were composed of similar cells, as was also the reddish purlo-lymphy looking matter in the aqueous chambers.

In conclusion, it need scarcely be remarked that the proposal to remove the eye, above referred to, was most unwarrantable.

### THE LONDON

### PRACTICE OF MEDICINE AND SURGERY.

### THE HOSPITAL FOR DISEASES OF THE SKIN.

THE compiler of the following report was for about three years a regular attendant of the practice of the Hospital for Diseases of the Skin. During that time he had the free permission of its Medical officers to take notes of any cases, and received also from them much valuable assistance in the prosecution of his inquiries. An excellent microscope, the property of the Hospital, was always on the table, and was resorted to in all cases requiring its assistance. In this way very numerous observations were made, and detailed notes of upwards of a thousand cases were taken. The main results of many of these investigations have already been recorded, either in the *Transactions of the Pathological Society of London*, or (more numerously) anonymously in the *Hospital Reports of this Journal*. It is proposed, however, in this and in several reports on special subjects which are to follow, to enter with more of detail into an examination of the disease selected. Thus taking, in the first place, the several diseases of the scalp, it is intended to bring the numerical method to bear, in the hope by its aid of finally setting at rest some of the many points in their pathology respecting which there is as yet much that is doubtful and disputed. This method has the great advantage of placing the writer and his readers on a footing much more nearly approaching one of equality than is otherwise attainable. The responsibilities of the writer are indeed greatly diminished, and his function is reduced to a considerable degree to that of merely collecting, compiling, and counting up facts. The same facts are before his reader as have been the subjects of his own investigation. Their exact number is known, and so also the degree of their detail and completeness. Any flaw in the conclusions deduced is easily exposed and corrected. That at first sight it is a tedious, lengthy, and laborious method must be admitted. It is, however, not so in reality, but tends rather, in the long run, greatly to save both time and trouble. An amount of labour, ingenuity, and valuable time has been expended in the discussion of certain Medical questions which might easily be named, and which are as yet just as doubtful as ever, which, had the numerical method been adopted, would long since have placed the truth beyond the reach of cavil. The observation of Dugald Stewart, that among the chief causes of the slow progress of human knowledge has been "A disposition to grasp at general principles, without submitting to the previous study of particular facts," will be corroborated by all inquirers, and by none more feelingly than by those who have been engaged in Medical pursuits. With this brief defence against the charge of prolixity, should any be inclined to bring it, we shall now pass to the subject in hand.

### REPORT ON THE NATURAL HISTORY, DIAGNOSIS, AND TREATMENT OF ALOPECIA CIRCUMSCRIPTA.

(Cases under the care of Mr. STARTIN and Mr. M'WHINNIE.)

DEFINITION. — Complete baldness in abruptly defined patches.

In proof of the necessity for a detailed examination as to the nature and characters of this affection, the following memorandum, made prior to commencing the inquiry, may be cited.

#### MEMORANDUM FEBRUARY 1851.

Writers on skin diseases do not appear to have sufficiently recognised the specific characters of this disease. It is the "Por-rigo decalvans" of Willan, and the "Accidental baldness" of Wilson. The latter makes no allusion to its great relative frequency in children, but seems to consider loss of hair in patches, when occurring in the latter, as usually a result of Tinea, from which Alopecia probably differs essentially in having no furfuraceous stage, in being never contagious, in occasioning no sensation of itching or tingling in the skin, and (?) in having no microscopic peculiarity (fungus in hair-root, &c.). Cazenave and Schedel thus ignore its existence as a special disease:—"Enfin l'alopecie partielle, décrite par Willan sous le nom de 'porrigo decalvans,' ne doit pas être considérée comme une affection distincte; elle est souvent le résultat des diverses espèces."

At the same date the following were marked out as the subjects to which attention was to be especially directed.

#### AGENDA.

1. To examine microscopically the hairs and hair-bulbs.
2. To ascertain whether in any cases it ever has any other stage or symptom than simple baldness. (Itching, scurfiness, vesicles, broken-up hairs, etc.)
3. To ascertain whether there is any evidence of its being a constitutional disease—especially liable to affect the delicate and puny—to follow fevers or severe illness—to be preceded by debility, emaciation, loss of appetite, or general languor—to recover and relapse coincidentally with improvement or the reverse in the general health—to be curable by remedies addressed to the general system.
4. To ascertain whether there is generally deficient vascularity or innervation in the affected portions of the scalp. This may be learned by scratching, rubbing it, etc.; also by watching the effect of blisters, and inquiring as to the degree of pain produced by them. (The idea of deficient vascularity is opposed by the circumstance that the patches are often very abruptly bounded, and that hair will grow luxuriantly on neighbouring parts.)
5. Is it ever communicable? In the cases in which it is asserted to have been communicated, in what period of its course did the transference occur, and was there reason to believe that the disease was then simple and uncomplicated?
6. How often is it associated with a general tendency to falling off of the hair of scalp, i.e. to thinning without the actual production of bald patches?

#### ABBREVIATIONS AS TO TEMPERAMENTS.

In the column in the table which relates to Temperaments abbreviations have been used. The meaning of these is explained in the following list:—

1. (Dark.) Black or dark brown hair and eyes.
  2. (Brown.) Brown (hazel) hair and brown eyes.
  3. Light brown hair and dark brown or black eyes.
  4. Brown hair and grey or blue eyes.
  5. Black hair and blue eyes.
  6. (Red.) Red hair and grey or blue or yellow eyes.
  7. (Light.) Light hair and light grey or blue eyes.
- Str. Strumous. Features tumid; large alæ nasi; snub nose; patchy colouring of cheeks; aspect heavy and dull.
- F. Str. Fair Struma. Transparent skin; features regular; eye brilliant and expressive; eyelashes long and silky; intelligent.
- P. Phlegmatic. Stout, fat, and flabby.
- C. Cachectic. Sallow earthy complexion; spare habit of body; lack-lustre eye; flabby, moist skin.
- R. Robust. Well fleshed; florid, of fixed and well-diffused colour.

No.	Name.	Age.	Temperament.	Health.	Diet.	Health at the time the disease appeared.	Date of appearance and duration.	Contagion.	Attended by scurf.	Tendency to get well, or to change its place.
1	Emma Jane Gentle.	7	7	Excellent.	Good.	Very good; a little losing flesh; appetite excellent.	Sept. 1853. 4 months.	None, although somewhat exposed.	Very little.	It has spread, but no hair has grown.
2	William Blanshard.	30	7	Fair.	Good.	Anxious; dyspeptic, but not very noticeably.	1848. 9 months this time 6 years.	None; very little exposed.	None.	It has been quite well once for several years; has returned in nearly the same parts; the hair generally is thin, and comes off plentifully.
3	Emma Ploughed.	8½	1	Good.	Poor.	Good; of poor parents and looks underfed; colour good and tongue clean; excellent spirits.	Jan. 1854. 1 month.	None, although very much exposed.	None.	None; it is spreading in all parts.
4	Sarah Bates.	20	2	Fair.	Good.	Not feeling well; head aches; no indigestion; catamenia regular; pale, but moderately stout.	May 1853. 9 months.	None, although considerably exposed.	None.	None; the patches are spreading at their margins; no hair has grown.
5	Rebecca Chipper.	6	2 R	Excellent.	Moderate.	Aged 18 months she had "water on the head," which has left a squint; she was improving in health and almost well when the disease began 3 years ago.	1851. 3 years.	None, although very much exposed.	None.	Always the same, gradually increasing in size.
6	James Reynolds.	12	2 R	Excellent.	Good.	Always had excellent health since the measles, which was at the age of 7.	1847. 5 years.	None, although considerably exposed.	None.	Always the same places, but gradually getting larger.
7	John Lever.	6	7 F St	Good.	Not good.	Appeared to have good health, but was losing flesh; appetite excellent; a delicate pale boy.	March 1853. 1 year.	Two sisters have had true ring-worm at the same time.	None.	Always the same place.
8	Elizabeth Henessy.	14	4	Fair.	Vegetable; very poor.	Dyspeptic; losing flesh; she has a furred tongue, and complains of having had flatulence and stomach ache; has been underfed; appetite good.	Dec 1853. 3 months.	None, although very much exposed.	None.	Always the same; the hair is loose all over, and thin.
9	Sarah Day.	5	7 Fl	Excellent.	Good.	A stout, florid child, well fed, and in every respect healthy.	Jan. 1853. 9 months.	None, although very much exposed.	None.	It began as a patch on the vertex, gradually spread at its borders, and in three months involved the whole scalp.
10	George Sumthwaite.	12	7	Feeble.	Poor.	Delicate at all times, but never especially ill; he looks pale and clear-skinned.	1848. 5 years.	None, although very much exposed indeed.	None.	On former occasions large patches have repeatedly been bare, and once the entire occiput; it generally falls off in Spring; it has several times been well over the whole head.
11	William Drinkwater.	11	2 Fl	Excellent.	Pretty good.	A robust and healthy boy, though not very strong; appetite good; digestion good.	Jan. 1854. 1 month.	None, although much exposed.	None.	Enlarging gradually; no change of place.
12	Robert Waite.	4½	..	Good.	..	....	Sept. 1853. 6 months.	None, though much exposed.	None.	Two patches have got nearly well.
13	George Hodgson.	14	7 D	Delicate; feeble.	Very poor.	Delicate; he is a starved-looking, ill-nourished lad; overworked.	March 1854. 1 month.	None, though very much exposed.	None.	It has not grown again, and is still falling over the whole scalp.
14	Thomas Spreadbury.	12	6 R	Good.	Very poor.	Quite good; he is liable to catch colds, but he is quite as well as usual; looks robust.	3 weeks.	None, though somewhat exposed.	None.	It has not grown again, and is generally worse; the patches are spreading.
15	Jane Raymond.	8	4 Str	Good.	Poor.	Quite good; she is, however, strumous-looking, though very hearty; moderately stout; has had scarlet fever 18 months ago, during convalescence from which the hair came off more than before.	1852. 2 years.	None, although very much exposed indeed.	None.	It has been gradually spreading; the hair has never grown again, but sometimes its fall has been arrested for a time.
16	John Dickenson.	14	4 R	Good.	Fair.	Quite good; healthy-looking, and robust. Is not subject to chilblains or cold hands.	6 months.	None, although very much exposed indeed.	None.	It has been gradually spreading; the hair has never grown again.
17	James Blows.	9	4 R	Pretty good.	Good.	Rather delicate, but looks florid and well. In winter suffers much from chilblains.	8 months, 3 years.	None, although very much exposed indeed.	None.	In 1852 he attended here, with the same disease of 3 months' duration, and was blistered; 10 weeks' treatment cured it; it has reappeared nearly on the same parts.

Attended by itching.	Position, size of the patches, etc.	Condition of the patches as to smoothness, hairiness, etc.	Microscopic Examination of Hairs.	No.
Considerable.	Vertex, occiput, and nape. Oval or round, 3-4 inches across.	Not quite smooth, but not actually scaly; a few scattered long hairs, and much down.	They all broke off abruptly; no bulbs extracted.	1
Very slight.	Vertex and sides of head; occiput. Large-sized, 4-5 inches across.	Smooth and glossy, but not thinned, nor yet quite bare of hairs.		2
Very slight.	Vertex, sides, and occiput; abrupt margins. Very large, irregular, and mapped out, involving altogether half the scalp.	Smooth and glossy, but not so polished as sometimes; a few solitary or grouped long hairs grow on them; no down.	Hairs taken from the midst of the patches; bulbs very much wasted—some of them tapered, others clubbed and black.	3
Very slight.	Front half of scalp, vertex, and occiput; margins very abrupt. The whole front of head, and many small scattered patches from a crown to a sixpence on back of head and occiput.	Smooth and glossy; quite denuded of hair; the head being shaved, it was seen, 1st, that where the hair grew the skin looked black; 2nd, it felt much thicker than over the patches; the latter were pale pink, not readily scratched.	Hairs taken from the margins of patches had much-wasted bulbs; those from the parts where the hair grew were many of them plump, but some of them wasted.	4
None.	Vertex. Irregularly oval, 4 inches by 2.	Perfectly smooth and glabrous; well defined and surrounded by thick-set hair.	Extremely wasted in the immediate border; good plump bulbs on rest of head.	5
Slight.	The entire occiput. Irregular patches; hair loose and thin in other parts.	Quite smooth. White-looking tufts, and irregular bands of thin-set but long hair, interspersed amongst the patches.	All the downy hairs of the patches had good soft plump bulbs; colourless.	6
Slight.	Scattered over vertex and occiput. There are six or seven, from a sixpence to a penny in size.	Skin thin, smooth, stretched-looking, all but bare; a few long thin hairs growing on them; no down.	The bulbs are wasted as compared with those of other parts, but not to so extreme a degree as sometimes; the spiral twist was seen in some of them.	7
None.	Vertex and occiput. 8 round patches on the vertex, and 2 on the occiput.	Quite smooth.	Those from and around the patch were very small, thin, and colourless, but their bulbs were plump; those taken from other parts of the scalp were many of them wasted to thread-like bulbs.	8
None.	The entire scalp. Eyebrows not affected.	At admission the whole head was quite smooth; now (3 months) there are a few short hairs, and a little down about it.	The down and short hairs have many of them plump bulbs.	
None.	Occiput. Small round patches, the size of half-crowns.	Smooth, but not quite destitute of hairs; much thinned.	The hairs drawn from the middle of the patches had good plump bulbs.	10
None.	Vertex and sides of scalp. The size of a half-crown on the vertex—nearly as large on each temple.	The patch on the vertex is smooth, but the skin is not so much thinned as sometimes.		11
No.	Vertex and occiput; the hair generally is thin. A half-crown; two others (smaller) are almost well.	Smooth and polished, but not quite destitute of hairs; some long ones grow over the whole patch; no down or broken hairs.	The bulbs on the patches are much less plump than on the rest of the scalp, but they are not wasted to any great degree.	12
No.	Vertex and scalp. A crown-piece, but the hair generally is very thin.	Quite smooth; the hairs in the patch pull out very easily, those in other parts adhere.	The hairs have lost colour, and are much thinned; the bulbs in comparison with shaft not so much wasted, excepting in a few; the hairs on the other parts have much attenuated bulbs.	13
No.	Vertex and side of occiput. A halfpenny and two crown-pieces.	Quite smooth; not quite destitute of hairs; the hairs look smooth, and hold tolerably.	Bulbs not for the most part in any way wasted.	14
No.	The back part of scalp. Almost the whole head.	Much of the vertex bare of hair and smooth; the whole scalp is very thin of hair, and the hairs come out with the greatest ease; many of them break abruptly off without splitting; the scalp is pale, but not very thin.	All the bulbs extremely wasted; this condition prevailed in almost all the hairs examined.	15
No.	Over the whole head in irregular patches. The hair is only remaining in small, scattered, and ragged tufts, excepting on the vertex.	Patches ill-defined, nearly smooth, not glabrous, some scattered hairs, and also some down.	Hair bulbs but very little wasted.	16
Slight.	Vertex and occiput. Quite smooth; 6 large well-defined patches, the size of crown-pieces.	Quite smooth.	Hair bulbs but little wasted.	17

No.	Name.	Age.	Temperament.	Health.	Diet.	Health at the time the disease appeared.	Date of appearance and duration.	Contagion.	Attended by scurf.	Tendency to get well, or to change its place.
18	Hannah Pearson.	5	3	Delicate.	Poor.	Has been getting thin, and is looking delicate. Is of variable temper and appetite. Generally eats well.	March 1853. 18 months.	None, although very much exposed indeed.	None.	Has continued on the same parts, steadily spreading; The hair gradually has become very thin.
19	Emma Farrell.	12	4 R	Good.	Good.	Had a little lost flesh, and had not so good an appetite as formerly, but there was nothing material amiss.	4 months.	None, but has been very little exposed.	None.	It has gradually increased in the patches where it first appeared.
20	Henry Stagg.	9	3	Good.	Good.	Has not lost flesh. Had no illness. Subject to swim-mings in the head, and occasional faintings; otherwise quite well.	1 year.	None, although much exposed.	None.	The hair has not grown where it had once come off, but the patches have not materially increased.
21	Henry Howe.	20	4 R	Good.	Good.	A red-faced, stout, robust-looking man. Generally good; had bilious fever 8 months ago, and was 3 weeks in bed very ill; 3 months after this the alopecia began; hair always loose.	5 months.	None, although much exposed.	None.	Has kept to the same patches.
22	Dorothy Quick.	10	4 C	Fair.	Very poor.	Pale and delicate; no disease or ill-health noticed at the time the hair began to fall.	3 years.	A sister who sleeps with her is said to have very [small] patches.	None.	It has changed its place often, and the hair has grown permanently on the part first affected, is worse now than ever before.
23	Elizabeth Rigby.	20	1 R	Good; stout; pale	Moderate.	Quite well; she had ring worm in infancy, and the hairs did not grow perfectly afterwards.	1848. 7 years.	None, though much exposed.	None.	It has often got nearly well and then again relapsed.
24	Joseph John Little.	12	1 R	Good; moderately florid.	Moderate.	Quite well in every respect; has a large quantity of jet black hair.	March 1855. 3 months.	None, though somewhat exposed.	None.	It has continued spreading.
25	Elizabeth Moxon.	8	1 R	Good; florid.	Very poor.	Good, excepting headache in back of head.	2 months.	None, although very much exposed.	None.	It has continued spreading.
26	John Scale.	41	4 pale	Good.	Moderate.	Good; had a three weeks' very severe headache, attended by frequent epistaxis. He was not used to epistaxis, and had hardly ever had headache before.	Sept. 1854. 5 months.	None; not much exposed.	None.	It spread in patches, the hair frequently growing again, and then again falling off.
27	James Smith.	28	2 dark	Good.	Moderate.	Was feeling quite well; small-pox 4 years ago; no dyspepsia; no headache.	May 1856.	None, though very much exposed.	None.	The patches now present are the original ones.
28	Emily Beven.	23	1	Fair.	Moderate.	Very good. States she had a bad "scald head," which got well after a short time, but the hair began to fall.	1842. 16 years.	None, though very much exposed.	None.	Does not change in place at all; the condition has been permanent for many years.
29	Edwin Coxsedg.	7	1 R	Excellent.	Poor.	Good; cause unknown.	Feb. 1852. 15 months.	None, much exposed.	None.	A patch of hair has grown on the larger one.
30	Sarah Springthorp.	10	7 R	Excellent.	..	Good.	1846. 6 years.	None, very much exposed.	None.	Almost stationary; the patch has become angular.
31	Henry J. Willis.	6	..	..	..	.. ..	..	Said to have given it to his sister.	None.	.. ..
32	Isaac Moon.	11	Str	Cachectic.	..	Delicate; a puny child.	Feb. 1851. 16 months.	None.	None.	None; in statu quo for 16 months.
33	Mary Ann Collins.	15	..	Excellent.	..	Good.	March 1851. 1 year.	None, though very much exposed.	None.	None; extending.
34	Henry Prett.	25	..	Good.	Good.	Good, excepting dyspepsia.	1845. 8 years.	None.	None.	None. After it had lasted five years, it was cured by stimulant inunction, but the hair again fell off.
35	Sarah Ann Phillips.	8	..	Excellent.	Poor.	Good.	April. 6 weeks.	None.	None.	None.
36	Jane Grossmith.	22	1	Cachectic.	..	Dyspeptic, and out of health.	..	None, though much exposed.	None.	None.
37	Eliza Dean.	23	..	Excellent.	Good.	Florid; excellent.	1849. 3 years.	None.	None.	Those originally affected are now covered with hair.
38	Amelia Spencer.	11	..	Excellent.	Good.	Excellent.	1851. 1 year.	None.	None.	None.
39	Mary Love.	19	1 Fl	Fair.	Good.	Looking very well, but states that she felt languid.	1851. 3 months.	None, though much exposed.	None.	None.
40	Eliza Shears.	16	1 Fl	Excellent.	Well fed on vegetables.	Looking very well, but thinner than before, having much headache and gastrodynia.	Oct. 1852. 1 year.	None, though much exposed.	None.	One patch has got quite well; the rest have with some variations been spreading.
41	Sarah Holloway.	21	1 Fl	Fair.	Well fed and comfortable.	Looking very well, but not considering herself so well as usual.	Dec. 1852. 10 months.	None, though much exposed.	None.	None.
42	Eliza Smith.	13	7 Fl	Excellent.	Good.	Stout, florid, and in excellent health.	Jan. 1852. 5 months.	None.	None.	None; Wilson's ointment has been tried for many weeks without advantage.

Attended by (itching.)	Position, size of the patches, etc.	Condition of the patches as to smoothness, hairiness, etc.	Microscopic Examination of Hairs.	No.
None.	Vertex and occiput. Some of them are the size of shillings; on the centre a patch as large as a palm.	Abruptly defined and bordered by stout hairs, quite smooth and glossy, but with a little down perceptible on close observation.	Hair bulbs wasted to mere threads; in other parts of the head some of the hairs have wasted bulbs.	18
None.	Vertex and occiput. One on vertex as large as the palm of a hand; three others the size of halfpennies.	Quite smooth; polished skin, thin, of pale pink colour, contrasting strongly with the black tint of the surrounding skin.	Not examined.	19
Slight.	On several distant parts of scalp. As large as half-crowns; some on the front much larger.	Quite smooth and polished, especially those on the vertex, where the scalp is much thinned.	Hair bulbs around the border of patch wasted to mere threads.	20
Slight.	Vertex, forehead, and occiput. As large as palm of hand, and as crowns.	Quite glabrous and smooth.	Not examined.	21
Slight.	Almost whole head in irregular patches.	Quite smooth, and abruptly circumscribed.	Not examined.	22
No.	The whole occiput, both sides of head, front of head, two small patches. Involving altogether more than half the scalp.	Quite smooth, hairless, downless, and very white and glossy; abruptly bounded by strong hair.	Not made.	23
Slight.	Vertex, occiput, and sides of head. Those on occiput and side size of pennies—at vertex much larger.	Quite smooth; well circumscribed, downless, but with a very few stumps.	The bulbs not very markedly wasted.	24
No.	Almost the whole head, especially in front. Very extensive.	Quite smooth; the patches circumscribed, but general thinning of hair.	The hair is growing so well that I did not examine.	25
No.	The scalp first, then whiskers and eyebrows. Entire scalp, eyebrows, eyelids, whiskers, beard, arms, etc.; not the axilla or pubes.	Quite smooth and soft; white; sensation good.	There were literally none to be got.	26
No.	Above the left ear; three on vertex. Five or six patches on different parts, round, smooth, and glabrous; largest the size of a crown piece.	Smooth and glabrous; skin thinned; hair on other parts well grown and strong.	Not made.	27
No.	Over the whole scalp. Almost the whole hair is destroyed, a few scattered patches of hair alone remaining; she wears a wig over the whole.	The patches are almost glabrous, or at best have but a little down on them.	Not made.	28
..	Vertex and occiput. 3 inches across, and size of half-a-crown; 2 patches.	A few long hairs; no down; quite smooth.	Not made.	29
..	3 large patches on crown of head, 4 inches across	Quite smooth, without either long hairs or down.	Not made.	30
..	2 large round patches, 2 inches across.	Quite smooth.	Not made.	31
..	Large patches, which at length became confluent, and almost covered the whole head.	Quite smooth, well defined, and surrounded by fringe of long hair.	Not made.	32
..	Large round patches.	Quite smooth and glossy.	Not made.	33
..	Almost the entire scalp is bald, with the exception of here and there a long hair or a small tuft.	Smooth, with here and there a long hair.	Not made.	34
..	Large patches on the back of the head.	Smooth.	Not made.	35
..	One large patch on back of head, amongst long black hair.	Smooth.	Not made.	36
..	Numerous isolated patches of large size.	Smooth and glossy.	Not made.	37
..	Large patch 6 inches across, on crown of head; smaller ones on occiput.	Smooth.	Not made.	38
..	4 large patches, 2 inches across; long black, thick-set hair in other parts.	Smooth and glossy.	Not made.	39
..	Many large irregular patches almost involving the entire posterior half of scalp. In the front is one round one (crown-piece).	Smooth and quite bare. The skin has papillæ, and is oily; readily made red by scratching.	Not made.	40
..	2; 1 on vertex, 2 inches oval, and 1 on occiput an inch across. General thinning of hair, previously luxuriant.	Smooth, and very nearly bare; papillæ with black points visible; easily reddened; blisters well.	Not made.	41
..	4 distinct very large patches.	Quite smooth.	Not made.	42

SATURDAY, FEBRUARY 13.

## EFFECTS OF PROSTITUTION ON THE ARMY.

In our former articles on the subject of Prostitution, we considered it only as a social and moral question. There is yet another point of view, however, in which it deserves to be examined, and particularly by Her Majesty's Government. Without any reference to their ultimate effects in the destruction of health, the diseases arising from this great social evil are causes of a large amount of inefficiency in the Army, and of consequent expense to the country. We are not aware that this has ever been fairly brought before the public, and we therefore propose, so far as the limited materials within our reach will permit, to show the great practical importance of the subject in this respect. It is, we admit, a much lower ground to take; but it may have influence with some of those—unhappily not a very small class—who endeavour to bring every question to the commercial test of £ s. d.

It appears from the Army Statistical Reports (a), that among troops serving in the United Kingdom, the admissions into Hospital from venereal diseases, including under that head not merely syphilis but gonorrhoea, and all other cases arising from impure connexion, amount to 206 in every 1000 cavalry soldiers, 250 in the Foot Guards, and 277 in every 1000 of the infantry of the line. The latter, however, being much more numerous than the others, the average proportion of admissions for the Army at home is 267 per 1000, or more than one-fourth of the whole number. The strength of the troops serving in the United Kingdom in 1848, the latest date at which we have been able to ascertain the numbers accurately (b), amounted to 62,587, including the Ordnance corps, and the number of venereal cases occurring among them must have been 16,733. We have no data to show the average period these cases remained in Hospital; but the Statistical Report already quoted, shows the average duration of each attack of sickness to be in the cavalry 15 days, in the Foot Guards 18, and in the infantry of the line 17 days. Considering that upwards of one-fourth of the cases admitted into hospital are venereal, we do not think we shall overstate their duration if we assume it to be the same as the lowest of these averages, or 15 days.

If, then, there are 16,733 cases of diseases of this class under treatment, each for fifteen days, while the men are receiving 1s. 1d. per day,—the lowest rate of pay of a private soldier (c),—the sum annually lost to the public from this cause will amount to £13,595, while the number of men constantly under treatment will be 688. In other words, Go-

vernment is deprived, by this cause alone, of the services of a number of soldiers nearly equal to the effective strength of a regiment on the home establishment, and at a cost of about £14,000. It is true that while a soldier is in Hospital 10d. a-day is stopped from his pay, to cover the Hospital charges for diet, etc.; but this is merely stating that Government does not, in addition to his pay, incur the expense of keeping him. While under treatment, he still costs the Government 1s. 1d. per diem, and for that pay he renders no service, but his duty must be done by another man, who also receives pay.

The average number constantly in Hospital of troops in the United Kingdom is between 4 and 5 per cent. of the force, and of these above one-fourth are under treatment for disease contracted by their own sensual indulgence. It is obvious, therefore, that everything which tends to diminish this must be a saving to Government, as it increases the number of effective men for duty. We have not entered upon the question of the consequences of venereal in inducing other diseases (as phthisis, for example), which increase the mortality and invaliding, and thereby augment the expense of keeping up the Army, because we are not aware of any accurate observations having been made on this important point. We entertain, however, a very strong opinion upon it, and allude to it now in the hope that some of the Army Medical officers, who have such excellent opportunities of tracing the same men through a series of years, will direct their attention to the subject, and afford to the Profession the means of settling the question, upon the incontestable evidence of accurate and ample statistical observations.

In the meantime we would call the attention of the military authorities to the importance, in a financial as well as moral point of view, of endeavouring as much as possible to restrain immorality, and thus diminish disease in the Army. We are not so utopian as to believe that it can be entirely suppressed, but much might be done by judicious measures to reduce it. Let the barrack-room—the soldier's home—be made more comfortable; let reading-rooms and coffee-rooms be provided in barracks, as well lit and as comfortably warmed as the canteen or neighbouring beer-shop; let books and means of recreation—draughts, chess, dominoes, &c. be provided, and we venture to assert that many of the men will find occupation and amusement who at present resort to the low dens of vice and debauchery to get rid of the discomfort of the barrack and the ennui of a soldier's life.

## THE WEEK.

THE Report of the Royal Commission of Inquiry into the sanitary Condition of the British Army has just appeared. The startling fact has been brought out that "if the army at home were as healthy as the population from which it is drawn, soldiers would die at one half the rate at which they die now," and that "at present the army stands almost at the head of unhealthy occupations in the united kingdom." The popular conclusion is that the Army Medical Department, and Dr. Andrew Smith as its head, are to blame; but a more unjust or erroneous conclusion could not possibly be arrived at. Dr. Smith and the officers of his department are constantly battling with the War Office in behalf of the soldier. His food, his clothing, his barrack and hospital accommodation, have been the subject of innumerable letters and remonstrances, and every improvement that has been obtained has been wrung from the authorities by sheer importunity. It is too bad to make a department responsible because it is powerless. Give us power to act, and then blame us if the result is bad. At present the Medical Department is absolutely dependent on the War Office, and the War Office will do nothing which costs money to improve the sanitary condition of the soldier.

(a) Statistical Report on the Sickness, Mortality, and Invaliding among the Troops in the United Kingdom. Presented to Parliament 1855.

(b) Parliamentary Return.

(c) The minimum pay of a private in the cavalry is 1s. 4d., in the Foot Guards 1s. 2d., and in the infantry of the line 1s. 1d. a-day, including beer-money.

until it is absolutely driven to it by the force of public opinion. All this shall be thoroughly exposed, and the true inference of the report must be established, namely, that the Medical department must be made omnipotent in everything relating to the sanitary condition of the British Army.

There is some hope that a change for the better may take place in the London dissecting-rooms. The students of some of the schools have memorialized the Examining Boards, requesting them to use their influence in procuring a more abundant supply of subjects at a cheaper rate; and Mr. Baco, the Inspector of Anatomy, has resigned. He is a gentleman very much respected and liked, but his administration of the Anatomy Act has ended in a total failure, amid just and universal dissatisfaction at the scarcity and high price of subjects. The Memorial of the Teachers of Anatomy in favour of Mr. Charles Hawkins, will be found in another column. The new Inspector will enter office at a most favourable juncture for himself, inasmuch as the dissecting-rooms can hardly be worse supplied than they are now. He must be judged by results. If next session the Schools of London are as abundantly and as cheaply supplied as those of Scotland and Ireland, he will gain great credit in a very easy manner. If anything like the present state of things continues we trust both teachers and students will join in a request to the Home Secretary, to remove an inefficient officer from an important post, and will endeavour to replace him by a better man.

We have been called upon by the *Daily News*, in a leading article, to substantiate certain statements we made as to persons who had been mutilated by the Sepoys. Our statement was, that we had been informed of these cases by Medical men. One was mentioned by Sir Charles Locock, who, on being referred to, gave as his authority a medical man at Brompton. This gentleman says the mutilated lady is a niece of one of his patients. We have applied to another gentleman, who "guaranteed" the authenticity of a second case, and have proposed that in both cases the patients should be seen by one or two gentlemen in whom the public would have full confidence. Should this be objected to by our informants it will become our duty then to adopt another course. In the mean time we may copy the following letter from the *Times*, premising that the Editor of that paper follows the rule we also invariably adopt, of never publishing an anonymous letter without receiving the real name of the writer in confidence, as a pledge of his good faith.

TO THE EDITOR OF THE TIMES.

Sir,—I believe that what Lord Shaftesbury stated at Wimbome is truth. I know two ladies and one child now in England—one lady has lost her nose and ears, the other nose, ears, and lower lip; the child is minus feet and hands. Can it be that these are the only sufferers? It must be evident to every one why the above and all others having been thus brutally used should wish to live in privacy.

London, Feb. 4.

AN EYE-WITNESS.

Death last week removed the oldest member of the Surgical Profession in Ireland—Robert Moore Peile, M.D. Mr. Peile was the last survivor of those who were admitted as surgeons on the granting, by his Majesty King George the Third, of the first charter to the College of Surgeons in 1784. At a very early period of his professional life he was appointed Surgeon to the House of Industry Hospital, with which he maintained his connexion until the year 1850, when he retired, receiving from his colleagues a well-merited address, expressive of their high appreciation of his private and professional character, and of their respect, esteem, and warm personal regard. He

also held the office of one of the Consulting Surgeons to Dr. Stevens' Hospital, a position he always regarded with pride and satisfaction. In the year 1795 he was appointed Surgeon to the Hospitals for the Forces serving in Ireland, and during the rebellion of 1798 saw active service in the field. In 1803 he was promoted to the rank of Deputy-Inspector of the Forces, an office which he continued to hold for the lengthened period of forty-four years. The first number of the "Dublin Medical and Physical Essays," published in March 1807, opens with a paper by Mr. Peile, on "An improved method of performing the operation of Lithotomy," in which he describes the instrument since known as "Peile's Lithotome and Staff." That Mr. Peile had, however, previously to the appearance of this paper, attained a high degree of celebrity for his performance of the operation in question, is evident from the following tribute, offered alike to the kindness of his disposition and to his professional ability, in the "Second Part of the Metropolis," a poem published in 1806, fifty-two years ago:

"Ingratulating manners, feeling mind,  
His hand as steady as his heart is kind;  
Through pathless darkness, dubious and untried,  
Like him, the deep-rate Gorget who can guide?  
Or steal, with delicacy's touch, away,  
The lens, whose cloud obscures the visual ray?  
Such skill, such worth our value must ensure."

Mr. Peile was a man of the most straightforward and upright character, and his conduct towards his professional brethren was ever marked by the most considerate delicacy. He long enjoyed an extensive and lucrative practice in Dublin, from which he had however retired many years before his death. He closed a long life of simple and unostentatious charity on the 4th of February, 1858, aged 93.

The following Advertisement and Circular may surely be allowed to tell their own tale. The address of Mr. James Barr is what is called a *Blue Poster*, intended apparently for the walls and doorways of the town.

"COLERAINE UNION.—The Committee of Management of the Coleraine Dispensary District will hold a meeting, on Saturday the 13th of February next, in order to appoint a competent person to fill the situation of Medical Officer to the above Dispensary, at a Salary of £90 per annum. Applications, enclosing certificates and testimonials of candidates, to be forwarded on or before Wednesday the 10th of February, and addressed to the Rev. James O'Hara, Hon. Sec., Rectory, Coleraine.

"Coleraine, January 23d, 1858."

"TO THE COMMITTEE OF MANAGEMENT OF THE COLERAINE DISPENSARY DISTRICT.

"GENTLEMEN,—Seeing an Advertisement in the *Coleraine Chronicle* from you, calling upon Candidates for the situation of Medical Officer to the above District to forward their Applications and Testimonials to you, I take leave now, after 27 years' practice in my native town, to offer myself as a Candidate; and, as economy is the order of the day, I propose to discharge efficiently all the duties of the Dispensary District for the Salary of £60 per annum.

"Let the Poor of the neighbourhood, however, distinctly understand, that if not elected,—and these elections usually depend more upon interest than merit,—I shall still continue to manifest the same kind attention to them as heretofore.

"JAMES BARR, Surgeon,

"And Licentiate of the Royal College of Physicians,  
"Edinburgh.

"Coleraine, 4th February, 1858."

Shall we ever or never learn the necessity of union and co-operation before we can expect to raise the position of the Profession?

The Weekly Return of the Board of Health appears this week in an altered form, the remonstrance against its discontinuance having been found effectual. It now appears as a weekly return on the Health and Meteorology of the Metropolis, communicated to the General Board of Health by the Metropolitan Association of Medical Officers of Health. The number just issued is No. 1, of Vol. II., but only accounts for the week ending Jan. 9. It is very desirable that it should appear on the same day, and for the same week, as the report of the Registrar-General.

Surely the most inveterate opponent of medical reform must admit the necessity of some check upon the false assumption of medical titles by ignorant pretenders to medical knowledge, when proceedings can take place at a Criminal Court to call forth such a letter as the following:—

"In the report of the proceedings at the Central Criminal Court given in *The Times* of Wednesday last, it is stated that James Cowan, an elderly man of very respectable appearance, was brought up to receive the judgment of the Court upon an indictment for misdemeanour, the offence imputed to him being that of exposing placards outside his premises containing offensive and disgusting expressions in relation to Her Majesty, the Royal Family, and other illustrious personages. The report says, 'The defendant, it appears, carries on the profession of a medical man in Westminster.' Will you permit me to state that he has no more claim to the title of medical man than to that of barrister or bishop? After having served in the Rifle Brigade, Royal Marines, and Newfoundland Veteran Companies, Cowan was discharged to pension as a private soldier. As to his very respectable appearance, I can only say that appearances are often deceitful. He has been known for many years as a nuisance to the neighbourhood in which he resides, as the police can well testify. It is but justice to the medical profession that they should not lie under the unjust imputation of having among them a member who could be guilty of the disgusting conduct for which this person has been sentenced to twelve months' imprisonment."

A Testimonial, consisting of a very handsome silver salver, was presented the other day by some of the members of the Pathological Society to Dr. Quain, on the occasion of his retirement from the office of Secretary. Dr. Quain had held that appointment, a purely honorary one, for five years, during which time he had devoted a large amount of most zealous energy and talent to the fulfilment of its duties. The high character of the volumes issued under his supervision is abundant testimony to the labour he devoted to them.

A book has just appeared, from the pen of Mr. T. D. Acland, late Fellow of All Souls College, Oxford, on the subject of the new Oxford Examinations for the title of Associate in Arts and for Certificates, proposed to be awarded during the present year. This volume, which will be read with great pleasure by all who take an interest in the spread of education, contains a very temperate and well written abstract of the chief objects contemplated in the new examination, and a refutation of the arguments of those who have placed themselves in opposition to the scheme. To us it appears that the recent step taken by the University of Oxford is worthy of all praise, and is likely to give a very powerful encouragement to the acquisition of useful knowledge throughout the country. There are abundance of good schools in England, and many hundreds of diligent and aspiring scholars, but for want of an examination-test by competent authority, superior ability is at present too often unrewarded and unappreciated, while incompetency remains undetected. The liberality of the University in the manner of carrying out its plan is also to be highly commended, for it does not restrict its honours to the alumni of any particular school, nor to the profession of any

peculiar religious denomination, but it throws open its honours to all who prove themselves worthy of receiving them. Nor are the distinctions which it proposes to confer granted only for proficiency in classics or mathematics; but general literature, science, and art, are included in the category of subjects for which titles and certificates may be bestowed. As far as our own Profession is concerned, there can be no doubt that whatever tends to improve the educational condition of the juniors who are preparing to join our ranks, must elevate eventually the intellectual condition of the whole body; and we are glad to find printed in Mr. Acland's book a memorial drawn up and signed by many members of the Medical Profession in London, to the Universities of Oxford and Cambridge, expressing the greatest satisfaction at the measures now proposed for guiding and testing the preliminary knowledge of those who may be destined for the pursuit of Medicine. We have so often advocated the necessity of an improved system of preliminary education for the youth of our Profession, that it is only necessary for us here to repeat this expression of our opinion, and to offer our warmest support to Mr. Acland's efforts and to the liberal and enlightened policy just adopted by the University of Oxford.

The *Northern Daily Express* of February 4 contains the following advertisement:—

**"PHYSICIAN'S ADVICE WITHIN REACH OF ALL.**

**D**R. PEARSE, for the last Six Years Resident Medical Officer to the Newcastle Dispensary and Fever Hospital, and Lecturer in the Newcastle-upon-Tyne College of Medicine in connexion with the University of Durham.

27, NEW BRIDGE STREET, NEWCASTLE.

FEE.—ONE TO TWO SHILLINGS, Visits and Medicine included."

Can this Dr. Pearse, by any possibility, be the Dr. Pearse described as follows in the Provincial Medical Directory:—

"PEARSE, John Samuel, Newcastle-on-Tyne. M.D. St. And. 1854; M.R.C.S. Eng. 1847; L.S.A. 1848; Lect. on Med. Jurisp. Newcastle Coll. of Med. in connexion with Univ. Durham; late Res. Med. Off. Newcastle Disp. and Fever Hosp. Author of 'Statistics of the Cholera Epidemic 1863, treated at the Newcastle Disp.; with the Chemical and Microscopical Examinations of the Secretions, and Observations on the Pathology and Treatment.'"

"Last week a lawyer was struck off the rolls for an act considered likely to lower the legal profession in public estimation. It is high time that our corporate bodies should be empowered to exercise a similar authority.

The festival of the Children's Hospital, on Wednesday, passed off most successfully, under the presidency of Mr. Charles Dickens, who made a most touching appeal in behalf of the sick children of the poor. Upwards of 23000 was added to the funds of this useful charity at the festival, including the sum of £900 from the ladies present.

Dr. Lankester, as Medical Officer of Health of St. James's has just issued a little tract of half a dozen pages, which is calculated to prove very useful; containing directions for the preservation of health, and for preventing the spread of infectious diseases. Everything which tends to impress upon the public mind the importance of cleanliness, fresh air, pure water, and wholesome food, must lead to the general good. How much disease might be prevented, for example, by the dissemination of such a statement as the following:—

"Water from pumps with surface wells should not be drunk. The following street pumps have surface wells, and

are liable to be charged with the leakage from sewers, cess-pools, and drains:—Bridle Lane, Brewer-street; Vigo-street, Regent-street; Burlington-gardens, Bond-street; Warwick-street, Regent-street; Broad-street, Golden-square; Marlborough-mews, Blenheim-street; Great Marlborough-street; Tichborne-street, Regent-street; Little James-street; Duke-street, St. James's-square; Charles-street."

We trust that other health officers will follow Dr. Lankester's example, and make known to their sanitary parishioners the causes of disease to which they may be exposed unknowingly.

## REVIEWS.

*On Sanitary Legislation and Administration in England.* An Address, portions of which were read before the Public Health Department of the National Association for the Promotion of Social Science, held at Birmingham in October, 1857. By HENRY WILDBORE RUMSEY. Pp. 77. London: 1858.

Mr. Rumsey is favourably known to the Profession and the public by his excellent "Essays on State Medicine," published in 1856; and he has done good service by bringing forward the same subject before the meeting held for the Promotion of Social Science at Birmingham last autumn. In this address he exposes, with great force, the existing defects in sanitary legislation, and recommends effective means for their removal; and it is to be hoped, that as the audience to which his remarks were addressed included some of the most enlightened social reformers of the present day, his remonstrances will not be made altogether in vain. He denounces, with great justice, the absurdity of making each parish or township the absolute judge of the necessity, or otherwise, of the introduction of sanitary measures; and he very truly observes, that those places which are most in need of reform in this particular, will be probably the most vigorously opposed to its introduction. What, he asks, would be the effect of limiting the administration of justice, the management of the poor, or the religious instruction of the people, to those places only which begged for their introduction? And he asks also, what would have been the result of limiting the Poor-law Amendment Act to the parishes which petitioned for its adoption, or of introducing the Constabulary Act only into those localities which confessed themselves so disorderly as to require the aid of its coercive enactments? And, "surely," he adds, "the application of general hygienic laws—often involving questions which have been or have to be solved only by repeated investigations of an abstruse and profoundly scientific nature—ought to be the very last duty of local administration, which a wise and strong government, acting upon the best advice, would leave to the option of any fraction of the community, on the ground of its assumed ability to judge for itself in such matters."

On the subject of the appointment of Medical Health Officers, and on the scientific acquirements necessary for the due discharge of their functions, Mr. Rumsey's observations are sound and judicious. He censures the anomaly of making these appointments only permissive in the case of provincial local Boards, while they are compulsory in the Metropolitan districts. In the latter case, too, although the appointments themselves are imperative, there are no provisions whatever for the efficiency with which their duties are to be discharged. The local Boards have absolute power to appoint and to remove; no general instructions from a scientific authority, and no medical laws are permitted to interfere with the peculiar views of any vestry or district Board. Although, too, it is admitted that many of the Medical Officers of Health are gentlemen of high scientific reputation, there is no competent authority to determine the capabilities of any candidate for the appointment, and the selection of a good officer must be merely a matter of accident. Again, as Mr. Rumsey pertinently remarks, if the Legislature has done wisely in committing the appointment of health officers to the local authorities, why has it deprived the local governments of all control over the County Court Judges? and if the medical officers must be chosen and dismissed at the option of the individuals forming our parochial vestries, why should not the American policy be adopted of leaving the executive and judicial, as well as

the legislative elements of government, to the direct popular choice?

Such are a few of the subjects discussed in Mr. Rumsey's excellent address, which is well worthy of the attention of our legislators; and we hope that when sanitary laws are under discussion in Parliament, they will resort for instruction and guidance to the perusal of its pages.

*Lectures on the Diseases of the Stomach and Indigestion.* By CATHCART LEES, M.B. T.C.D., Physician to the Meath Hospital. Pp. 237. Dublin: 1858.

Dr. Lees apologises in his Preface for the appearance in print of a course of Lectures on Diseases of the Stomach at a time like the present, when so many good works on the same subject are before the public; but, nevertheless, he thinks that they may be found well adapted for students, for whom they were originally intended. They are founded on practical experience; after having been delivered in the Meath Hospital and elsewhere, they have already appeared in the pages of a Dublin contemporary, and they are now presented in a revised and amplified form. On looking over the pages of Dr. Lees's work, we find that he has carefully studied the works of those authors who have written on the pathology and treatment of the diseases of the stomach, and, as a course of lectures to students, his treatise is worthy of great commendation. The rules of treatment are given with clearness and conciseness, and may be considered as trustworthy guides for the practitioner.

*Toothache and other Affections of the Teeth relieved by the Electric Caustery.* By THOMAS H. HARDING, Surgeon-Dentist. London: 1858.

In this pamphlet Mr. Harding strongly advocates the use of the electric caustery, which was introduced into Dental Surgery in 1844 by M. Louyet, of Brussels. The battery employed is that of Smee, consisting of six pairs of plates of zinc and platinized silver, set in action by dilute sulphuric acid. The poles are connected with platinum wires, the extremities of which are introduced into the diseased tooth-pulp, and on completing the circuit the platinum wire becomes hot, and destroys the vitality of the exposed nerve. It is said that by this process toothache is often cured, and that the diseased tooth may remain serviceable for many years.

## PROGRESS OF MEDICAL SCIENCE.

### Selections from Foreign Journals.

#### ON THE ARREST OF PULMONARY TUBERCULOSIS.

By Dr. FLINT.

In this paper Dr. Flint furnishes the details of 24 examples of arrest of phthisis that have occurred in his own practice, and then makes some interesting observations upon the circumstances which seem to favour such arrest. The number might have been much increased had he not excluded such cases as were too recent, or the subsequent histories of which had not been sufficiently followed up, and those in which the disease was not arrested but simply slow in its progress. The evidence of arrest was decided from the fact of well-marked symptoms progressively abating in intensity, the patient increasing in weight and strength. "Until within late years, instances of supposed recovery from phthisis were unreliable in consequence of the want of certainty in the means of determining the presence of the disease. This uncertainty has been removed by the discovery and improvement of the physical exploration of the chest. Physical signs in conjunction with symptoms render the diagnosis of pulmonary tuberculosis positive in the great majority of cases. I shall include in this collection only cases in which the diagnosis rests on the conjoined evidence of signs and symptoms. With some exceptions, the results of exploration of the chest, together with the previous history and existing condition of the patient, were noted prior to the arrest of the disease. In a few instances, however, the cases came under observation subsequently to the arrest, and the diagnosis was made retrospectively; that is, the physical signs and previous history were

deemed sufficient to render it positive that the patient had been affected with tuberculosis." In the narration of the author's cases a marked distinction is made between "arrest" and "recovery." Arrest it is obvious may take place without recovery, when the tuberculous affection ceases to be progressive, but the processes of restoration never being complete; recovery can only be said to have occurred when, in connection with restoration of the general health, the local symptoms have entirely disappeared. Of the 24 cases in 13 arrest of the diseases was followed by complete recovery, while in 11 arrest was alone demonstrated.

"In several of the cases the arrest of the disease was evidently due to an *intrinsic tendency* to that result; in other words, the disease ceased to be progressive, in consequence of its self-limitation. This is fairly to be inferred in those instances in which no appreciable external influences, in the form either of medication, diet, or regimen, were brought to bear in the course of the disease. Eight of the cases may be embraced in this category." The fact of such intrinsic tendency Dr. Flint believes is not sufficiently appreciated, having been, indeed, only of late recognised; and adds, that while it is probable that the arrest of tuberculosis, supposed to be brought about by the measures resorted to, is really in more or less of the cases actually due to the self-limitation of the disease; so it is to be supposed that this intrinsic tendency has been sometimes thwarted by injurious therapeutical or other means—especially when it was the custom to resort to the antiphlogistic course of treatment. In the cases here detailed no resort was had to antiphlogistic debilitating measures, such as depletion, mercurials, emetics, low diet, confinement, &c.: and it may be fairly asked whether an abstinence from such measures did not contribute to the favourable result.

The occurrence of hæmoptysis occurred in no less than 18 of the 24 cases. In 10 of the 18 it occurred more than once, and in some several times. The proportion exceeds that in which hæmorrhage may be expected to occur in phthisis, according to the researches of Louis (57 of 87 cases), proving that the symptom is not an unfavourable one as regards arrest; the fact according with the conclusion arrived at by Walshe, that the occurrence of hæmorrhage does not hasten the progress of the disease, but appears to produce an opposite effect. It also agrees with the inference from observations in individual cases in which hæmorrhage seems to take place in lieu of a fresh tuberculous exudation.

Comparing the 14 cases, in which measures of treatment were adopted, it is found that in nearly all a change was made in the habits of life, such change consisting in relinquishing, partially or entirely, sedentary pursuits, and giving proportionately more time to *exercise in the open air*. In 5 of the cases this change in habits constituted the sole treatment, while all the 8 patients in whom the disease was arrested without any measures of management were persons of active habits of life. We are, therefore, warranted in regarding out-door occupation as conducive to this result. "The exercise in the open air was not generally of the kind which often goes by that title, consisting in simple airings by gentle walks or drives; but it consisted in rough occupation, often involving considerable, and sometimes great exposure to vicissitudes of weather." *Change of climate* occurred only in two cases prior to evidence of arrest. "On this subject I have been led to conclusions to which others have also arrived, viz. that climate, in itself, exerts no special agency in determining an arrest, but that it may favour this result indirectly by affording better opportunity for exercise in the open air, and furnishing objects of interest to the mind which will secure that object. . . . It has seemed to me far less important to fix upon a situation supposed to be the most favourable in its climatic aspects to the tuberculous patient, than to select a residence where the inducements to active habits of exercise are greatest. To place a patient in a group of invalids, in a particular spot where he is expected to derive some specific remedial influence from the atmosphere is rarely useful. The *ennui* incident to such a position, for a man of active habits of mind and body, is intolerable, and the moral effect of his associations is injurious. Patients will do wisely in avoiding the favourite places of resort for those affected with the disease, and in choosing points where the incitements to and the resources for physical exertion abound. Generally the objects of a change of climate are better secured by frequent change of place than by remaining stationary. Travelling in foreign countries, even when, so far as the climate is concerned, the

change is for the worse rather than the better, may be in a high degree useful, because the exercise which it invites is not endured as a task, but accepted as a means of mental gratification."

With respect to *diet*, the object was not to lower the powers of the system, but on the contrary to support and develop them by nutritious food. The patients were encouraged to live generously, indulging and cultivating an appetite for any and all the varied wholesome articles of food, with a full proportion of meat. In consequence of carbonaceous alimentary principles appearing to be useful in the management of phthisis, and the alleged fact of the comparative freedom from the disease enjoyed by persons working in sugar houses, Dr. Flint advises the free use of sugar. "It is a significant fact, apparent on referring to the cases I have reported, that appetite and digestion were, in general, not greatly impaired. It accords with the views just expressed to regard an unimpaired appetite and digestion as highly favourable for an arrest of the disease. Observation undoubtedly shows us instances in which the tuberculosis is progressive notwithstanding the ingestion and apparent assimilation of nutritious food; but it probably can show few examples of arrest of the disease when, either from disinclination or injudicious management, the diet is insufficient for the full support of the body, or fails to be appropriated to that end. No part of the management of tuberculosis seems to me of greater importance than that relating to the diet; in fact, whatever efficiency belongs to active habits of exercise, it is reasonable to suppose, is in great measure exerted by means of the increased activity of the processes of assimilation thereby induced." Diffusible stimuli, as wine, beer, and spirits, entered more or less into the management of a considerable number of these cases. They were given in moderate quantities, subsidiary to alimentation, i. e. contributing to render the digestive processes more active and complete. "I have of late advised their use much more freely than formerly, and I think I cannot be mistaken in attributing to them much value. I have observed that patients affected with tuberculosis are often able to take spirits in large quantity without experiencing stimulant or intoxicating effects. The disease appears to be one of those in which these effects are with difficulty produced."

Beyond mere palliatives, little use was made of *medicinal agents* properly so called. No remedies were given with reference to their special influence on the tuberculous cachexy, unless cod-liver oil can be so regarded. Tonics were often ordered, with the intention of influencing the processes of digestion and assimilation; and in this point of view they must be regarded as important agents. Cod-liver oil does not hold a very conspicuous place in these cases. Several of them occurred before it came into vogue; and in other cases it was taken for too short a period, either from the repugnance or the disturbance of the digestive organs it gave rise to. In very few instances was it persisted in. "Had a larger number of these cases occurred within a more recent period, or were I to report the cases during the last few years in which the progress of the tuberculosis appeared to be greatly retarded, although not arrested, this remedy would be found to enter more generally and often largely into the treatment. That it is a valuable remedy I can scarcely entertain a doubt; but it is to be considered that, since it has become emphatically *the* remedy employed in this disease, improved pathological views and the lessons of experience have wrought a radical change in the management of the disease as regards other measures—a change consisting in the abandonment, to a great extent, of antiphlogistic and debilitating measures, and a recognition, more and more, of the importance of measures of an opposite character."

"A point pertaining to the *mental constitution* of persons affected with tuberculosis seems to me worthy of notice. As regards the successful management of the disease, much depends on the patient's energy and perseverance. Tuberculous patients, as is well known, usually entertain sanguine expectations of recovery; but in a large proportion of cases they expect recovery to take place without any extraordinary agency on their part to secure that result. The disease, while it engenders hopes which are so often fallacious, seems frequently to impair that determination of purpose without which the means requisite to effect an arrest will not be efficiently pursued. A passive expectancy of recovery, and a calm acquiescence in the prospect of a fatal termination, belong to the natural history of the disease. On referring to the

cases which I have reported, I find that, in general, the persons manifested greater resolution than is usually associated with the tuberculous cachexy. This was due in some instances to innate strength of character, and in other instances to the force of circumstances."

"In conclusion, the general views which, with our present knowledge, are to govern the management of pulmonary tuberculosis may be summed up in a few words. The ends to be attained are, the removal of the cachexy on which the progress of the disease depends, the consequent arrest of the disease, and the promotion of the processes of restoration. There is no special medication to be pursued for the attainment of these ends; they are to be attained by measures which, in general terms, develop and strengthen the power of the system. This mode of expression, it is true, in a scientific point of view, must be considered rather vague, but in a practical sense it has a meaning sufficiently definite. The measures are hygienic rather than medicinal; but much importance often belongs to the latter. The hygienic measures which are most important are laborious exercise in the open air conjoined with agreeable mental occupation, and as conducive thereto, frequently change of business, the selection of a more eligible climate, and travelling are desirable, if not necessary; generous diet, and in many, if not most instances, the free use of alcoholic stimulants. The medicinal remedies, in addition to those which are simply palliative, are chiefly those of the tonic class, and in this category may be included the analeptic which has of late years had so much celebrity."—*American Journal, Med. Science*, Jan., pp. 52—86.

#### TREATMENT OF EPILEPSY.

By Dr. BROWN-SEQUARD.

Dr. Brown-Séguard concludes a long series of papers upon the nature and etiology of epilepsy published in the *Boston Journal*, with the following propositions as to the treatment of the disease. 1. The first thing to be done in a case of epilepsy is to find out if its origin is peripheric. The state of all the organs must be inquired into as completely as possible. 2. If it be ascertained that epilepsy is of peripheric origin, employ proper means to separate the nervous centres from this origin, or to remove the cause of the excitation entirely. Leaving aside what relates to the viscera, the application of ligatures, as we have shown, ought to be first tried. Sometimes it happens, as in a very curious case recorded by Reclamier, that the aura will disappear from one place and reappear in another. It will be well to pursue it thither and apply ligatures in the new place. 3. If ligatures fail, this is no reason for despairing of other means having the same object. The nerve animating either the part of the skin from which originates the aura, or the muscle or muscles which are the first convulsed, must be laid bare, and sulphuric ether thrown upon it. This might perhaps be sufficient to cure the affection. If it is not the nerve must be divided. 4. The amputation of a limb for epilepsy is a barbarous act, the section of the nerves being all that is necessary. 5. Sometimes blisters, setons, caustics, etc. in the neighbourhood of a part which is the origin of an aura, may be sufficient to cure, but these means have not the same efficacy as the application of a red-hot iron. 6. The best means of treating epilepsy seems to consist in the application of a series of moxas along the spine, and particularly the nape of the neck. 7. The nutrition of the nervous centres may be modified, and epilepsy be thereby cured, principally by the medicines which act on the blood-vessels, such as strychnia, but particularly by those which determine contractions in these vessels, such as atropia, ergot of rye, etc. 8. Trepanning, in cases where a blow on the head, or some other circumstance, seems to indicate it, ought not to be resorted to until cauterization and other means of producing a modification of the conditions of the skin of the head have failed. 9. Cauterization of the mucous membrane of the larynx, which has been successful in some cases in which there was considerable laryngismus, is an excellent means, not only of diminishing or preventing the spasm of the larynx, but as a mode of producing a modification in the nutrition of the medulla oblongata. 10. As a means of treatment too much neglected, we will point out the possibility of the transformation of epilepsy into intermittent fever, which has been proved by the important facts observed by Selade, Dumas, and others. The frequent passage of an intermittent fever into epilepsy, and the facts which show that nerves of the blood-vessels are excited in the nervous centres in fever and ague (the galvanization of the cervical sympa-

thetic nerve produces the effects of this fever, viz. cold, soon followed by warmth and perspiration), show also that there are great analogies between epilepsy and ague. So it is as regards the efficacy of ligatures in both diseases. That intermittent fever is an affection of the nervous system, is proved by a curious case of fracture of the spine, in which the parts paralysed remained in their normal state, while the rest of the body exhibited the phenomena of a paroxysm of fever. (*New York Journal*, 1861, p. 199.) 11. We will merely add, that hygienic means are as important as the treatment, and that sleeplessness ought to be as much combated as the disease itself. 12. As regards the treatment of the fits, we cannot insist too much upon the prevention or diminution of asphyxia, as it seems certain that the circulation of black blood in the nervous centres prepares for the production of future fits. For this object the best means are dashing very cold water in the face, and the inhalation of chloroform.—*Boston Journal*, vol. lvii. p. 265.

#### EXCERPTA MINORA.

*Iodide of Potassium in Leucorrhœa.*—Dr. Payne recommends the iodide of potassium as an injection in leucorrhœa. It is to be used (31½ to a pint of water), 3 or 4 times daily.—*American Medical Journal*, Jan. p. 296.

*Belladonna in Orchitis.*—M. de Larue recommends the following application, which, he says, promptly relieves the pain, and leads to a cure in a mean period of 8 days. Lard, 60 parts; aqueous ext. of belladonna, 16 parts. It should be applied gently every 2 hours in considerable quantity, the parts being afterwards covered with a linen compress, which is to remain unchanged.—*Rev. Med.*, Jan. p. 61.

*Compression of the Carotids in Epilepsy.*—In the case of a young man who had suffered from more than 500 epileptic attacks within the space of 8 years, Dr. Reiner tried the effect of compressing both carotids until the complete cessation of the pulsations. This procedure, practised 22 times on the first appearance of precursory symptoms, always had the effect of reducing the paroxysm to a few almost insignificant convulsive movements. Meanwhile the patient's general condition, both bodily and mental, has greatly improved.—*Ibid.* p. 53.

*Mortality after Operations in Paris.*—Dr. Mac Pheeters, of Natchez, in a letter from Paris to Dr. Cartwright, states that in the Parisian Hospitals it is the exception rather than the rule for a patient to recover after an amputation of the leg. At first he was inclined to attribute this to the enfeebled condition of Hospital patients; but M. Nélaton, in a lecture on this subject, stated that equally fatal results occur in private practice. Nélaton accounts for this great mortality by some peculiarity in the atmosphere of Paris, which produces purulent absorption; for in the provinces similar operations are performed with much better results.—*Boston Med. Journal*, vol. lvii. p. 327.

*Confection of Cinchona as an Antiperiodic.*—Dr. Gloninger strongly recommends a confection of cinchona (made of the Calisaya bark) as a most effectual and agreeable preparation, sitting easily on the stomach and unproductive of the inconveniences which sometimes follow the use of quinine. Its tonic properties apply excellently to the convalescence from fevers. He believes that a fair trial of the confection will lead to its superseding all other anti-periodics. ℞ Cort. cinch., calis. pulv. conf. sennæ, aa ʒi.; ammon. muriat. ʒ½, syr. cort. aurant. ʒij. M.—Dose the size of a "shellbark" three times a-day.—*American Journal Med. Sci.*, Jan. p. 294.

#### FOREIGN CORRESPONDENCE.

##### FRANCE.

Paris, February 6th, 1858.

In our last letter we noticed an interesting communication of M. Briquet to the Académie de Médecine, on the nature of pain in lead colic. This able Physician has read a second paper at the same Academy on the treatment of this painful affection. He has employed galvanism, or rather electromagnetic currents (the Faradisation of Duchesne), upon 42 patients, most of whom had a simple attack, and only one-fifth had other effects of lead poisoning. Constantly (and without one single exception) the pain has disappeared com-

pletely at the cessation of the Faradisation, and it was not reproduced by pressure upon the walls of the abdomen in any direction. Twenty-four patients have had no return of the pain after the first Faradisation. Ten patients have had a return of the pain, which has disappeared definitively after the second Faradisation, made on the same day as the first, or the next day, and in one case after eight days. In seven patients the pain has definitively ceased only after the third Faradisation, and in one only after the fourth.

The effect of the Faradisation was not limited to the cessation of the pain; the various morbid disturbances constituting an attack of lead colic gradually disappeared. The appetite often returned the day after the beginning of the treatment; vomiting ordinarily did not take place but a few times only for one or two days. In a number of patients (about one-half) constipation ceased only on the fourth day. The patients had taken no purgative.

M. Briquet concludes from these facts, 1st. That it is not the retention of fecal matters which causes the pain in lead colic; 2nd. That it is not the pain in the abdominal wall which paralyzes the bowels; 3rd. That, therefore, purgatives do not cure by voiding the bowels. Besides Faradisation, he has employed either no other treatment, or only sulphurous baths, sulphuric lemonade, alum, and opium. The results have been just the same whether they took these medicines or not. When other effects of lead poisoning exist together with the symptoms of lead colic, they persist after the treatment by the Faradisation. The application of a continuous galvanic current (with Pulvermacher's chain) procured an amelioration, but no cure.

A discussion of some importance has taken place at the Société de Chirurgie, on the treatment of abscesses by congestion. The mode of treatment employed by M. Boinet and others, who consider it as having been successful in some cases, has been criticised energetically by some members of the Society. This treatment consists in injections of iodine into the cavity of the abscess after it has been emptied. M. Marjolin states that he has not had a single success, although he has tried this means in seven or eight adult patients and several children. M. Demarquay and M. Chassaignac have also failed. In some few cases, M. Larrey has succeeded in ameliorating the condition of his patients, but he attributes this good result as much to the means employed at the same time as the injections of iodine, as to them. Giralès also thinks that the success probably has been due to the coincident means of treatment as much as to the injections. However, some cases have been mentioned which seem to show that this mode of treatment may prove very valuable. M. Forget has related a case cured six years after many injections of iodine.

Professor Claude Bernard has made to the Académie des Sciences a more extensive communication than that of which we spoke in one of our last letters, on the differences of the colour of the blood coming from glands during their activity and their periods of inactivity. He has succeeded, by various means, in suppressing the urinary secretion, and found that the venous blood came black from the kidneys in such a case, while it flows out red when the urine is secreted. The same thing he finds with the sub-maxillary glands, which, when they do not secrete, have their venous blood black, while it is quite red, and even scarlet, when the gland secretes either by a reflex action, as when an acid is put on the buccal mucous membrane, or when the nerve of the gland is galvanized. At the time that the gland is active, more blood flows out of it than in the opposite condition.

*Annual Public Meeting of the Académie des Sciences of Paris.*—*Distribution of Prizes.*—The prizes to Medical men are the following:—

1st.—Prizes of Medicine and Surgery: to M. P. Broca, for his work on Aneurisms; to Messrs. Delafond and Bourguignon, for their researches on the Animals of the genus *Sarcop*; to M. Morel, for his work on the Physical and Moral Degenerescence of Idiots, etc.

2nd.—Prizes of Physiology: to M. Muller, for his discovery concerning the changes of form of the Lamprey; to M. Brown-Séquard, for his researches on the properties of Red and Black Blood.

A report made by M. Devergie, to the Académie de Médecine, in the name of a Committee, is now exciting discussion in this Academy and in the Medical press. The principal object of the report is to establish the possibility of the transmission of the *herpes tonsurans* of animals to

man. The report relates facts observed by M. Reynal, which seem to prove positively the existence of such a transmission, at least from horses and oxen to man. Before M. Reynal, several veterinary surgeons and physicians had recorded such cases, but they had not positively proved the contagiousness of the affection. In his report M. Devergie remarks that the *herpes tonsurans* of animals may generate either the same kind of herpes in man, or produce the *herpes circinnatus*. He thinks that these two varieties of herpes are due to a parasitic cryptogam, the *trichophyton*.

M. Moreau states that the *herpes circinnatus* in the human species is not contagious, and as a proof of this assertion he states that he has known husbands attacked with the disease for years, and who had not communicated it to their wives. He thinks the *herpes circinnatus* is incurable.

M. Devergie says that Bielt has ascertained that this kind of herpes is contagious. If it depends upon the presence of a cryptogam, the persons exposed to contagion, and who have resisted it, were not in favourable conditions for the development of the plant and its influence on the skin.

M. Depaul blames M. Devergie for having attributed the merit of the discovery that the *herpes tonsurans* and *circinnatus* are caused by the *trichophyton*, to Baerensprung, who published his views only in 1855, while M. Bazin, of Paris, had already proposed the same opinion in 1854.

M. Devergie shows that M. Bazin cannot be considered as the discoverer, because he thought that the existence of the *trichophyton* was not a constant one.

## GENERAL CORRESPONDENCE.

### THE ANATOMY ACT.

[To the Editor of the Medical Times and Gazette.]

SIR,—As you did me the honour to insert my former letter on the Anatomy Act, I am emboldened to make a few further suggestions on the same subject.

Mr. Bacot, the late Inspector, has resigned before the termination of the session, thereby necessitating the appointment of another Inspector without any opportunity being given for the fair discussion of the question in all its bearings, or any alteration in the Anatomy Act. However, we are only too glad to get quit of him, and must look for better things from his successor.

The Anatomical "Lecturers" have, I believe, agreed to recommend Mr. Charles Hawkins for the post, but whether he will prove the right man in the right place is, I think, doubtful. If Mr. Charles Hawkins really wishes to work his office effectually, he must not only devote his own energies to the work, in no inconsiderable degree, but must have subordinates who thoroughly understand their part also. What is wanted is a "Purveyor," a man of respectability, but not of too high position, who is thoroughly up to all the "dodges" of the undertakers, and who could constantly be going about, looking them up, and procuring as many bodies as possible. The Inspector of Anatomy cannot do this himself; he may influence Boards of Guardians and other great people, but he cannot get at the inferior workhouse officials, with whom it greatly rests whether a body be "unclaimed" or no. It is astonishing what an effect a shilling or two, judiciously laid out, will do in this way, and the Purveyor could manage it all with the greatest facility. It will cost something, no doubt, but upon a proper representation to the Home Secretary additional funds would surely be allowed for the purpose. I presume that the new Inspector will exercise some control over the undertakers' charges, and not leave us entirely at their mercy as at present, for if so, we may expect in a few months that the price of subjects will be raised again, perhaps doubled, without our having any redress.

I am, &c.

DEMONSTRATOR.

### ARTIFICIAL RESPIRATION.

[To the Editor of the Medical Times and Gazette.]

SIR,—I have no wish to enter into any controversy in your valuable paper on the Asphyxia question, but cannot refrain from making a few remarks on Dr. Silvester's letter in your last number.

In that letter Dr. S. describes *three* experiments which "were performed with the view of elucidating the subject of artificial respiration," in connexion with the method he has proposed and contrasted with the Marshall Hall method, over which he believes his own has numerous advantages.

I have, on a former occasion, (a) shown the physiological inferiority of Dr. Silvester's method compared with that of Marshall Hall; I showed how, theoretically, the method was not so good, because the prone position was not adopted, and I have since witnessed experiments on the dead body confirmatory of what I then said.

My present object is to show how unlikely the three experiments, made by Dr. Silvester, are to establish his method as one more serviceable to the asphyxiated than that of Marshall Hall.

"The following," says Dr. S., "was the mode of using the apparatus. The glass tube was passed *through an aperture made in the trachea*, and firmly secured in its place by a ligature, etc."

Surely this is not the way to prove which mode of restoring an asphyxiated person is best. The very point in question, the great object of the inquiry, is entirely overlooked by Dr. S. in his way of performing the experiments. The chief difficulty to overcome in cases of asphyxia (apnoea), is to get air the best way possible into the trachea through the semi-lifeless relaxed tissues at the back of the tongue, the chink of the glottis, the mucus and liquids collected about these parts, etc. These overcome, the task is comparatively easy. Marshall Hall tackled these difficulties, and overcame them; he adopted the prone position (for expiration) to open the glottis, to let the tongue fall forwards, to remove liquids, etc. from the mouth, nose, pharynx, etc. and semi-rotation for inspiration and inflation of the chest, which inflation of the chest is sufficient, and more than sufficient, for natural respiration, as shown by a second coadjutor (b). But in the subject of "deep practical interest," Dr. Silvester quite overlooks this the most essential point, and performs his experiments on the lungs having got rid of the grand difficulty one meets with in the asphyxiated by passing the glass tube (as shown in his plate) into an opening in the trachea.

I am, etc. A COADJUTOR IN THE DISCOVERER'S  
St. George's Hospital. EXPERIMENTS.

#### CASES OF FOREIGN BODIES IN THE EXTERNAL EAR.

[To the Editor of the Medical Times and Gazette.]

SIR,—I beg to send you the following particulars of two cases, one of which has excited public notice.

*Case 1.*—*Pea in the external meatus.*—*Attempted removal with tweezers and forceps, followed by inflammation and suppuration.*—*Acute pneumonia.*—*Death.*—Robert Sinclair, aged 8 years, an only child, son of a lighterman, residing at 46, Commercial-road, Rotherhithe, tall, fair, and of strumous constitution, was taken to my surgery on the 2nd of last December, by his mother, who informed me that while playing with peas the preceding day he placed one in his ear, and could not get it out. His schoolmaster, on finding what had occurred, told him to hurry home, as he would not live many minutes. She accordingly took him at once to some friends, who poked the ear with tweezers, etc. in order to extract the pea; but failing to do so, he was taken to my house, and in my absence he was attended to by my assistant, who syringed the ear well, though ineffectually. On the 2nd, when he was first seen by me, I repeated the syringing; but as the poor little fellow was so dreadfully alarmed, I could not do it efficiently, and being aware of the previous ill-advised attempts with instruments, I recommended his removal to St. Thomas's Hospital. On the 3rd the mother called, and stated that she took him to St. Thomas's, where he was held down on a table by five or six persons; that efforts were made to extract the pea, and that it was taken out in pieces. I desired her to keep him very quiet; to give him a dose of castor-oil, and to let me know on the occurrence of unfavourable symptoms.

On the 7th he complained of severe pain in the ear and all over the temporal bone. The meatus was tumefied, and there was a slight purulent discharge. The pea appeared to me to

be still discernible at the bottom of the ear, and on applying the breast-bag over the ear, the suction moved it a little. Ordered poppy fomentation, linseed meal poultices, and anodyne at bed-time.

8th. Had a better night, but still great pain, and more inflammation and discharge. To have leeches to back of ear, and saline effervescing draughts; feet in warm water and mustard at bed time.

14th. I was informed that the pea, swollen as large as a cherry, had come away this morning. I did not see it, as unfortunately it was thrown into the fire. To have a blister behind the ear, and cold applications to the head, as the mischief is increasing fast.

16th. Seen for the first time at his own home. Delirious at times; sick, and no action of bowels. Continue the effervescing draughts, and to have 2 grains of chloride of mercury every 3 hours.

17th. Great fever—quick pulse; rigors followed by heat, perspiration, and then cold again. No action of bowels. To have an enema, more leeches to the temples, and cold applications to head, and hair removed.

20th. Head symptoms still continue increasing in spite of blisters to the back of neck, cold applications, mercurials, etc., and the discharge from the ear (sometimes tinged with blood) continuing to increase to several spoonfuls daily. The powers of life now began to flag, and stimuli were resorted to.

On the 21st, very acute pneumonia set in, somewhat relieving the cerebral symptoms, and he died (of apnoea) on the 24th.

*Case 2.*—*A large cherry-stone in the external meatus of a boy 6 months, without any inconvenience; its removal without difficulty, by means of syringing.*—This boy, James Rutherford, aged five years, was taken to me by his father, who became alarmed on seeing the foregoing fatal case reported in the newspapers. He stated that his little son had frequently told him during the past half-year that he had put a cherry-stone in his ear, and that he had pain there, and upon examining the ear the preceding day he saw it distinctly. I syringed the ear well, and directed almond oil to be dropped into the ear daily for a week, when I repeated the syringing. The oil was continued another week, the breast-bag applied, and the syringing repeated a third time, when the cherry-stone, a very large one, came away, and with it all symptoms of deafness and pain disappeared.

Comment on the foregoing cases is unnecessary, I believe that had the first case not been meddled with, though the pea would have been still in the ear, the boy would have survived. The acute pneumonic symptoms appeared to be secondary, and entirely dependent on the inflammation of the internal ear. And in the last case did not the boy escape by the father not believing his son's story, and no one attempting to hook it out by means of instruments?

J. J. CREBORN, M.D.

Rotherhithe.

#### LIGATURE OF THE CAROTID.

[To the Editor of the Medical Times and Gazette.]

SIR,—In the number of your Journal, Jan. 23, there is an account of the particulars of a case of fungus hematodes involving the right half of the face, where I tied the common carotid artery, in St. Bartholomew Hospital, to arrest the hæmorrhage which was almost daily taking place.

I do not wish to enter into the question as to whether or no the operation was justifiable. Whatever may be the opinion of others, I acted upon my own responsibility, but with the concurrence of some of the most experienced of my colleagues, and after giving the case my anxious consideration. There is an important fact, however, which I would wish to see corrected. Upon examination after death there was found *no softening of the brain*. In one part the capillary blood-vessels seemed a little fuller than natural, but the cerebral substance was firm and healthy. Paralysis must have ensued from disturbance of circulation, but there was no change which could have rendered recovery impossible.

In another case of similar character, I should be disposed to perform the operation at an earlier period, before the patient had sunk into almost a state of collapse, for the tying the artery is a speedy and not very painful performance; and inasmuch as it offers the patient a chance of prolongation

(a) Medical Times and Gazette, Nov. 14, p. 513, 1857.

(b) Medical Times and Gazette, Dec. 5, 1857, p. 588.

of life, if successful; on the other hand, it arrests hæmorrhage even if the fatal issue of the case be more speedy.

I know of no condition more pitiable than that of a man, the subject of an incurable disease, slowly bleeding to death; nor any position more distressing than that of a Surgeon who should be forced to stand by and witness the lingering death of his patient by such a process.

I am, etc.

HOLMES COOTF.

26, New Bridge-street, Feb. 10.

## MEMORIAL OF THE SCHOOLS OF ANATOMY.

[To the Editor of the Medical Times and Gazette.]

SIR—I enclose for publication in your Journal a copy of a Memorial which was signed by delegates from *all* the Schools of Anatomy in London, at a meeting held on the 3rd inst., and was transmitted on the following day to Sir George Grey, with a request that he would give it his favourable consideration.

I am, etc.

RICHARD PARTRIDGE,  
Chairman of the Meeting.

17, New-street, Spring-gardens.

"The Teachers of Anatomy in the Medical Schools of London having heard of the resignation of Mr. Bacot, are most desirous of having the appointment of Inspector filled by a gentleman thoroughly conversant with the working of the Anatomical Department of the Hospital Schools. The Teachers think that such a person should not himself be engaged in teaching at any hospital, in order that he may be independent of all individual interests; that he should possess sufficient weight and character in the Profession to secure the co-operation of the teachers and of the parish authorities; and be of such an age as to ensure activity and energy in the discharge of his duties.

"The Teachers feel the difficulty of finding a man who combines these qualities, but they believe that Mr. Charles Hawkins possesses them in a remarkable degree, and without wishing to intrude their recommendation upon the Secretary of State, they venture to express their strong conviction that the appointment of Mr. Charles Hawkins would be a great gain to the practical study of Anatomy in this Metropolis, and that he would carefully carry out the provisions of the Anatomy Act, with a due regard to the wants of the Medical Profession, and a just consideration for the feelings of the friendless poor.

"London, Feb. 3, 1858."

## OPIUM IN UTERINE HÆMORRHAGE.

[To the Editor of the Medical Times and Gazette.]

SIR,—In the correspondence which has appeared in the *Medical Times and Gazette* on the effects of opium in uterine hæmorrhage, it appears to have been forgotten that opium has a very different effect, according as it is given in *large* or *moderate* doses. Considering the physiological action of the drug as described in "Pereira" and other works on *Materia Medica*, it appears likely to be useful, or the contrary, in diminishing hæmorrhage according to the dose in which it is administered; a *very full dose* being likely enough to produce relaxation, whilst a moderate dose, without doubt, produces contraction of the uterus. Most of your correspondents have given cases with a view of showing the relaxing effect of opium on the uterus, when administered in *full doses*. The following case, though not one of uterine hæmorrhage, very well illustrates the stimulant action of the same medicine when given in moderate doses. Two years ago I was requested to attend Mrs. A. in her confinement with her first child, she being in the 43rd year of her age: of course I expected a tedious labour. She lived in the country, and I was obliged to remain with her forty-eight hours before the labour was completed. She had suffered much for many hours; the liquor amnii had escaped—the os uteri was not completely dilated—she had taken sufficient nourishment to prevent exhaustion from want of food, chiefly gruel and toast and tea. No progress had been made. The pains, though severe, were badly borne and inefficient, when I administered what I considered the best stimulant, viz. about 25 drops of laudanum in a little water. The effect was much better than I even expected. The pains became almost directly more

powerful and expulsive, the os uteri rapidly disappeared from the reach of the finger, and the head soon began to press upon the perineum. More than twelve hours afterwards the case was exactly in the same condition with regard to the perineum as it had been before with regard to the os uteri. The pains continued to be severe, but ceased to have any expulsive action; the pulse quickened, and other signs of exhaustion began to appear. I repeated the laudanum in the same dose as before, having the forceps in reserve, in case the opium should have no effect. In about ten minutes the stimulant effect of the medicine began to show itself, the pains soon again became powerful and expulsive, and with the aid of pressure on the fundus of the uterus with the hand during each, in about half an hour the head was born. Another pain expelled the child, another the placenta; the uterus contracted firmly, and everything went on well. Mrs. A. was up and in her sitting-room within a week,—without leave, for I thought it too soon,—but no harm followed.

I could relate other cases showing the same effect of opium, but for the present enough. I am, &c.

Bewdley, Feb. 5, 1858.

JOHN GARR.

P.S.—Of course opium will not produce uterine contraction under all circumstances. It is only in cases of deficient power from exhaustion or fatigue that it is likely to act beneficially; and I may mention that inertia of the uterus is a condition particularly requiring its administration in moderate doses; for at the same time that it produces contraction, it prevents the effects of the loss of blood. The above, though the real effect of opium in moderate doses, may appear strange at first sight. But how frequently must every practitioner have observed the suspended action of the uterus in consequence of the hasty and improper administration of brandy and other stimulants, by nurses and midwives! the effect is of every-day occurrence.

## REPORTS OF SOCIETIES.

### THE PATHOLOGICAL SOCIETY.

TUESDAY, JANUARY 19.

Dr. WATSON, President, in the chair.

(Concluded from page 103.)

MR. HUTCHINSON exhibited, on behalf of Mr. BORLASE CHILDS, a specimen of

#### ANEURISM OF THE ARCH OF THE AORTA.

The interest of the case attached chiefly to the fact that the symptoms of laryngeal obstruction produced by the aneurism had been such as to lead to the performance of tracheotomy. A man, of about 30, had for some months had difficulty in breathing, and occasional hoarseness. At length the dyspnoea became very distressing, and paroxysms would occur, in which death by suffocation seemed imminent. Immediately after one of these tracheotomies, as a precautionary measure, was performed. It gave some relief; and although the permanent difficulty in breathing remained, yet no further paroxysms occurred. He sank, and died on the second day. The autopsy showed an aneurism of the arch of the aorta of considerable size pressing upon the trachea, which it had somewhat flattened. The rings of the trachea were all but exposed by ulceration. The left recurrent laryngeal nerve had been stretched on the tumour, and hence, no doubt, the cause of the spasm of the glottis. Mr. Hutchinson adverted to a very similar case, in which, at St. Thomas's Hospital, tracheotomy was performed by Mr. Le Gros Clark some years ago, and remarked that the diagnosis in both was exceedingly obscure. The cause of the dyspnoea was twofold: 1st, the compression of the trachea; and 2nd, the irritation of the recurrent nerves. Of these, the operation was efficient in preventing the influence of the latter, but could do nothing as regards the first.

#### MR. HUTCHINSON also showed specimens from cases of EXFOLIATION OF TEETH IN HEREDITARY SYPHILIS.

These were instances of periostitis of the alveolus soon after birth, ending in the exfoliation of the crowns of the yet undeveloped teeth. In the first, the infant was a month old when

the first tooth came away, and in the second six weeks. Both were the undoubted subjects of inherited syphilis. In the first, at different times during two months, the crowns of five teeth and a considerable portion of the lower jaw exfoliated; and in the second, the crowns of four teeth. None of the teeth had fangs, and most of them were notched and irregular on their edges, being as yet imperfectly formed. Mr. Hutchinson adverted to the rarity of this occurrence in hereditary syphilis; he had himself only known of one other case, and he was not aware that it had been mentioned by any writer. It was, of course, wholly distinct from the premature loosening of teeth after having been cut, attended with exfoliation of portions of alveolus, and not very unfrequently observed in unhealthy children. As illustrating disease of yet undeveloped structures, the cases threw important light on the origin of certain conditions often observed in after life in those who in infancy had suffered from syphilis. Just as a majority of nodes get well without suppuration, so, in all probability, inflammation of the alveolus and tooth-pulps very often passes off without causing exfoliation. To such inflammation occurring during the process of dental development were no doubt due the conditions of irregularity, unequal size, serrated edge, etc., so often seen in the teeth of the subjects of inherited syphilis.

Dr. O'CONNOR inquired whether the mothers of these patients had taken mercury during pregnancy, as he was inclined to suspect that that drug had more to do with the exfoliation than syphilis.

Mr. HUTCHINSON replied, that neither of them had been subjected to any treatment whatever. A warm discussion followed, in which Dr. Brinton, Mr. Henry, Dr. Snow, and Mr. Hutchinson, took part, respecting some of the laws under which syphilis is transmissible to offspring. Dr. Brinton held that a father could not transmit the disease to his child, and that it was necessary that the mother herself should have suffered in order to contamination of her fetus; while Mr. Hutchinson contended that transmission by the father alone was not only capable of as clear proof as could be expected from the nature of the subject, but was of very frequent occurrence.

The PRESIDENT inquired whether the iodide of potassium was not preferable to mercury in the treatment of these syphilitic affections of the osseous system.

Mr. HENRY stated that he thought it was, and that he generally employed the iodide of iron.

Mr. HUTCHINSON stated that he had no reliance on any other remedy against infantile syphilis than mercury. He had often used the iodide, but never alone. Inunction with the mild mercurial ointment, as advised by Sir B. Brodie, was, he felt convinced, by far the most efficient method of treatment.

## HARVEIAN SOCIETY OF LONDON.

JAN. 21, 1858.

Dr. SIEVEKING, Vice-President, in the Chair.

### FUNCTIONAL PARALYSIS.

Dr. HANDFIELD JONES mentioned the particulars of two cases of what he would be disposed to call "functional paralysis." The first was that of a girl, aged 19, who, having been unwell for three weeks, was suddenly seized with paralysis of the extremities, loss of consciousness, etc., which only lasted, however, a short time, and from which she recovered, and was convalescent in three weeks. The second that of a boy, aged 17, affected with slight sickness, impaired memory, and inability to hold objects in the hand for any time together. In both cases tonics were successfully administered; in the first case cod-liver oil and strychnia, and in the second a preparation of iron. Dr. Jones considered that in cases of this kind the paralytic condition depended on an impaired or weakened state of the nervous centres, for which tonics were the appropriate remedies.

A paper was then read by H. C. STEWART, Esq.

### ON THE EPIDEMIC DIARRHŒA OF THE PAST SEASON (1857).

Mr. STEWART had been led to bring before the Society some remarks upon the epidemic diarrhœa of the past season, from

having observed that it presented features in many cases very different from the ordinary summer diarrhœa of this country. During the summer of 1855 bronchitis was concomitant with, or followed as a sequel on, diarrhœa, in many cases occurring in his practice; and in 1856 hydrocephalus was likewise observed to accompany or follow diarrhœa. These peculiarities determined him to keep short notes of all cases coming under his care during the past summer; and he trusted to be able to show, from the results of his observation, that the epidemic in question was characterised by the presence of an increased irritation of membranes in a disease formerly looked upon as very simple. From the 23rd of June to the 20th of October, 1857, he had treated 98 cases, classed as follows:—Simple diarrhœa, 82 cases, followed by secondary choleraic diarrhœa in 15, and by dysentery in 18 cases; the choleraic diarrhœa was followed by dysentery in 2 cases, and collapse in 1 case as tertiary diseases; choleraic diarrhœa occurred as a primary disease in 16 cases. The term "simple diarrhœa" he employed to denote those cases where the alvine discharges were liquid but fecal, vomiting and cramp being absent—in other words, painless diarrhœa; "choleraic diarrhœa," when the alvine discharges were very copious, watery, tinged with bile—also when rice-water stools, vomiting, cramps, acute pain, or spasms, more or less coldness of surface, with chilly sweats, were present; "dysentery," when the alvine discharges were watery, mixed with bile or not, and containing more or less bloody mucus, or pure blood, with tenderness over the abdomen upon pressure, and occasional acute pain, vomiting absent or not, as the case might be. Cases illustrative of the forms alluded to were mentioned; in one of the dysenteric cases, the febrile symptoms accompanying partook of the typhoid type. Mr. Stewart remarked that all these cases of dysentery followed on the simple form of diarrhœa, and not on that of the graver form of choleraic diarrhœa, for which circumstance he was not prepared to give a reason, and all of them had been neglected in the earlier stages, Medical aid not being sought until the symptoms became alarming.

*Treatment.*—The following plan of treatment was found efficacious:—In simple diarrhœa and also in choleraic diarrhœa, eliminants—as calomel, with or without opium, followed by a draught containing rhubarb and tartrate of potash; the after treatment consisting in the administration of ten grain doses of bicarbonate of potash, with carminatives every four hours. Diet—milk, farinaceous food, and cold brandy and water. Respecting the treatment of the dysenteric form, the author had been disappointed in the usual remedies for dysentery, but found the diacetate of lead in doses from one to six grains with dilute acetic acid and opium, taken every three or four hours, the most beneficial remedy. The diet consisted of milk, farinaceous food, beef-tea, and cold brandy and water.

The deaths were 4 or 4·08 per cent. Without troubling the Society with sanitary or meteorological remarks, the author wished to refer to some circumstances which he thought required particular notice.

*Influence of Sex.*—Females were more affected than males in the proportion of sixty-four of the former to thirty-four of the latter. A large proportion, 34·69 per cent. of the whole, consisted of children under five years of age (sixteen males and eighteen females).

*State of the bowels and motions previously to the attack.*—In fifty-nine cases they were confined, in twenty-nine regular, in ten relaxed. The motions were clay-coloured in ten, dark bilious in four, green in two, and not noticed in eighty-two cases. He thought much information was to be derived from observing the previous state of motions, and regretted that so little notice was taken by patients generally of them. Many of these cases might have been prevented by a little attention to these particulars. The ten cases of relaxed bowels were in infants, not cases of actual diarrhœa, but in which the motions were looser than usual.

*Hour of attack.*—Mr. Stewart had found that 88·108 per cent. of the attacks occurred between midnight and midday, and 11·026 per cent. from midday to midnight. The seizures commencing at midnight increased rapidly until 3 a.m., when they reached their culminating point, gradually declining until 9 a.m., increasing somewhat from 11 a.m. to 7 p.m., and again decreasing until midnight, the primary, secondary, and tertiary attacks maintaining the same ratio. The author considered these circumstances of great importance, and agreed with Dr. Handfield Jones in his remarks upon catarrh,—"That the nightly paroxysms were due to a lowering

of the nerve power during the night, and consequent dilatation of the arteries, the basomotor nerves partaking of the general debility; hence hyperæmia of the affected part increased, more irritation is set up, and exudation takes place." Mr. Clarke, in a communication to Dr. Graves, stated—"That the electricity of the atmosphere is at its daily minimum at 3 a.m., and that the atmospheric pressure has one of its two daily minima an hour later—4 a.m." Mr. Stewart remarked that the larger number of attacks of diarrhoea took place at 2 a.m., 3 a.m., and 4 a.m., the numbers being respectively 16, 37, and 30, while there were only 3 at 1 a.m., and 4 at 5 a.m. So that the greatest number occurred at the periods of the least amount of daily electricity and that of the greatest amount of daily atmospheric depression, as well as of that when the vital powers are lowered by the natural actions of daily labour and subsequent sleep. Staff-Surgeon E. J. Burton informed him that in India, the Crimea, Canada, and Africa he observed the majority of attacks of diarrhoea, cholera, dysentery, and fever to occur during the hour of sleep.

Mr. Stewart stated that in all his cases he found the symptoms to be aggravated from 1 a.m. to 4 a.m., and that while recovering under treatment the nightly paroxysms remained longest, but those at 3 a.m. would be the last to leave. The days would often be entirely free, but the patients were invariably worse during the night. Mr. S. next stated, that out of the 98 patients, 74 had neglected the earlier symptoms, mentioning a case of dysentery which nearly proved fatal thereby. The state of the motions when the cases were first seen were then passed under review. He found them clay-coloured in 30, dark bilious in 7, green in 10, watery mucous 23, rice-water 6, bloody in 20, pale mucous 2.

Mr. Stewart then concluded his paper by a few brief remarks upon the effects of free heat upon human life and health, reviewing the unusual degree of heat of the past summer, and its effects in producing an immense number of cases of dyspepsia, cephalalgia, and other diseases of a low nervous type, which he thought would help to elucidate its effects as a cause of the disease under consideration. His experience during a practice of twenty years was, that the primary seat of the disease is not in the liver and stomach and bowels, but in the nervous system. Heat is the exciting cause, producing debility of the nervous powers; owing to want of due nervous power, the liver and gall-bladder cease to perform their proper functions, or performed them imperfectly; hence the congested liver, clay-coloured motions, flatulence and acidity, followed by irritation of the mucous membranes, diarrhoea, and its consequences.

Dr. Randsen considered the cause of the epidemic was to be looked for in some other conditions than simply atmospheric ones, these having been always in operation, whereas the disease was one comparatively new. He had not observed the dysenteric element in the late epidemic to the extent mentioned by the author of the paper.

After some remarks by Mr. Ballard and Dr. Camps,

Dr. Headlam Greenhow stated, that dysentery had, he believed, been very extensively prevalent in many parts of the country during the last season, and from what he had himself observed, the dysentery was accompanied by ulcerative changes in the colon as in regular dysentery. He was disposed with the author of the paper to admit the influence of the extreme heat of the weather during the last summer in giving rise to the epidemic of diarrhoea.

## PARLIAMENTARY INTELLIGENCE.

### HOUSE OF LORDS, FEB. 9.

#### ARMY SANITARY COMMISSION.

LORD PANMURE laid on the table the report of the Commissioners to inquire into the Sanitary Condition of the Army. The report was most voluminous, but he could assure their lordships that it would well repay perusal. It reflected the highest possible credit on the commissioners who drew it up, and he could not forbear from expressing the sense he entertained of the services of those gentlemen, and more especially that of his right hon. friend Mr. Sidney Herbert, who presided over the commission. (Hear, hear.)

## OBITUARY.

### MR. JOHN SEPTIMUS ALDERSON.

WE regret to record the death of John Septimus Alderson, Esq., Medical Superintendent of the West York County Asylum, West Riding House of Correction. The deceased gentleman was son of the Rev. W. Alderson, late Rector of Everingham. He was a pupil of Mr. Henry Dunn, Surgeon, of Wakefield. After passing his examination as a medical practitioner, he became assistant to the late eminent Mr. William Hey, of Leeds. After the lapse of some years, he was appointed Resident Medical Officer to the York County Asylum at York, and held that appointment four years. In the year 1847, he was selected out of about forty candidates as the successor of Dr. Powell (to whose daughter he was subsequently married), in the Superintendency of the Nottinghamshire County Asylum; and from that important office he was, on the resignation of Dr. Corsellis in 1853, elected to fill the still more arduous situation of Superintendent of the West York County Asylum. "The great improvements effected during Mr. Alderson's short directorship over the Wakefield Asylum," says the *Wakefield Journal*, "bear testimony no less to his industry and zeal than to his constructive talent. The reorganisation of the airing-grounds more especially, and the reorganization of extensive portions of the interior of the edifice, with a view to the better accommodation of an ever-increasing population (apart from the acknowledged success of his general management), entitle him to the praise of having faithfully acquitted himself of duties of no ordinary complexity, delicacy, and difficulty. His manly, frank, independent bearing, a temperament in which firmness was blended with true kindness of heart, have greatly endeared his memory to a community which had the best opportunities for estimating the real worth of his unpretending character."

## MEDICAL NEWS.

UNIVERSITY OF CAMBRIDGE.—The following gentlemen have passed the examination of the Downing Professor of Physic:—

BENNINGTON, St. John's  
BROWNE, Corpus.  
CHEADLE, Caius.  
DEAN, St. John's.

DUDDING, Trinity-hall.  
GRAYSTONE, St. John's.  
HAYWARD, Corpus.  
NUNN, St. John's.

ROYAL COLLEGE OF SURGEONS.—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted Members of the College at the meeting of the Court of Examiners on the 29th ult.:—

BRADLEY, FREDERICK, Tipton, Staffordshire.  
DIXON, FREDERICK, Brighton.  
ELLIS, WILLIAM, Morley, near Leeds.  
EVANS, GEORGE HENRY, Manchester.  
MAYSMOR, HUMPHREY LEVERINGTON, London.  
MIDD, JOHN, Stockport, Cheshire.  
WILKINSON, FREDERIC EACHUS, Sydenham.  
WILLIAMS, JOHN, Pen-y-bryn, Wrexham, North Wales.

APOTHECARIES' HALL.—Names of gentlemen who passed their examination in the Science and Practice of Medicine, and received Certificates to Practise, on February 4, 1882:—

BRIGHT, RICHARD STONEHEWER, Croydon.  
EVERET, WILTON, Arundel, Sussex.  
HARRIS, ABRAHAM, Gwennap, Cornwall.  
USHER, THOMAS STEVENSON, Jekley.

### DEATHS.

BROWN.—Feb. 1, at Preston, Lancashire, Robert Brown, M.R.C.S. Eng. 1821; F.R.C.S. 1852; L.S.A. 1821. Aged 58.

HALL.—Jan. 23, at Boyle, Lodge Hall, M.D. Aged 85.

NORGATE.—Feb. 8, at Hastings, B. H. Norgate, of Norwich, F.R.C.S. Eng. (Hon.) L.S.A. 1823. Aged 55.

REA.—Jan. 23, at Ryton, James Lambert Rea, of Balman Village.

## APPOINTMENTS.

DR. JOHN RYAN, has been appointed Medical Officer to the South City Dispensary, Grand Canal-street, Dublin, in the room of Dr. Head, resigned.

The Queen has been pleased to appoint ETIENNE AUGUSTE MANGER, M.D., to be Surgeon-General for the colony of British Guiana.

**MUNIFICENT BEQUEST.**—Mr. Benjamin Sutton of Leicester, who died recently, having observed that patients, on their discharge from the County Infirmary, were often reduced to circumstances of deep distress, has bequeathed a sum of about £30,000, that, in all cases where it may seem desirable, the authorities of that institution may give a sum not exceeding £5 to such patients as they shall think fit objects; the relief, in all cases, to be in money.

**ANNUAL MEETING OF THE BELFAST BRANCH OF THE MEDICAL BENEVOLENT FUND SOCIETY OF IRELAND.**—The annual meeting of the above most useful and philanthropic society was held on Monday; Dr. Patterson presided. The society is neither a benefit society nor an assurance club, but a strictly charitable institution, founded and promoted for the express purpose of assisting medical men when struggling under the pressure of sickness, or any other casualty. This, it should be known, is its primary object. But, under circumstances of urgency and distress, the society affords relief to the widow or family of a professional man, who may have been deprived of the support and affection of either a husband or parent. Having made this reference to the society's general purposes, we have only to add, in regard to the annual meeting of this local branch, that, after the transaction of some routine business, the subscribers proceeded to the election of a permanent president, Dr. Stevenson having resigned that office—one which he filled with much zeal and ability during the last ten years—when Dr. Henry Purdon was unanimously appointed his successor. Professor Gordon having likewise begged to be relieved of his office of treasurer, which was reluctantly consented to, Mr. Browne, R.N., was elected in his place, and Dr. R. Stewart was reappointed the honorary secretary.

**ILLEGITIMACY IN SCOTLAND.**—The last monthly return of the births, deaths, and marriages registered in the eight principal towns of Scotland, published by authority of the Registrar-General, contains the following statement:—"During the month of January there were registered in the eight principal towns of Scotland the births of 2684 children, of whom 1434 were males, and 1250 females. Of that number 2447 were legitimate, and 237 illegitimate. This gives the very high proportion of one illegitimate to every 13½ births; in other words, nearly 9 (8·8) per cent. of the births during the month were illegitimate. As such facts are chiefly of value when contrasted with those ascertained in other places, it may be mentioned that in London the average proportion of illegitimate births is only about 4 per cent. of the total births; in Liverpool, the proportion is about 4½ per cent.; in Birmingham, under 5 per cent.; and in Manchester, about 6 per cent.—while the proportion for all England is under 7 per cent. of the births. It may also be stated that, generally speaking, the proportion of illegitimate children is higher in country than in town districts, notwithstanding the ordinary impression regarding the greater immorality of towns. A single month's returns may, however, give a false estimate of the annual proportions, so that too much weight must not be attached to the above figures. As the Maternity Hospital in Edinburgh drafts off this class of cases from Leith, in giving the proportions for each town, Edinburgh and Leith will be considered as one town. The proportions of illegitimate births in each town will therefore stand thus:—In Paisley, 6·7 per cent. of the births were illegitimate; in Glasgow, 6·9; in Greenock, 7·3; in Edinburgh and Leith, 9·7; in Perth, 13·1; in Dundee, 13·5; and in Aberdeen, 13·7."

**GYMNASTIC PRIZES AT THE SALPÊTRIÈRE.**—An interesting ceremony took place at the Salpêtrière, consisting in the distribution of prizes to the children in the gymnasium of the hospital. Gymnastic exercises are now under the able care of M. Laïsne, carried on in that hospice, as well as at the Enfants Malades and the St. Eugénie, for the relief of diseases of the nervous system, and especially chorea. M. Blache states that of 108 cases of children so treated, the cure was obtained in 102. The children exhibited their exercises both with and

without gymnastic implements; and they all take great delight in the performance of what to most of them becomes a valuable means of treatment. Those in the establishment who have been thus cured are retained to superintend the application of the means to the recently admitted patients.

**FRENCH STATUE OF JENNER.**—The plaster model of the statue of Jenner is to be erected at Boulogne, where were inoculated the first children in France. Jenner is represented as standing upon a portion of the terrestrial globe, meditating on his discovery. At his feet the words "France and England" are inscribed. In his right hand he holds a lancet, while his left arm rests upon his works supported by an ancient broken column. In front and near the knee are drawn the serpent and the cup, while by the side of the column on which the books rest, a scroll hangs down representing a cow.

**CHEMICAL ACCIDENT.**—A rather serious accident took place recently in one of the lecture rooms in the Pesth University. A compound formed of cyanide of mercury and hydrochloric acid exploded, wounding Professor Wertheim and his assistant in the eyes. The pupils, seized with a panic, rushed to the door, and some jumped out of the window. In leaping out they broke a vessel placed beneath the window containing the hydrochloric acid, and several were injured by the fluid.

## TO CORRESPONDENTS.

### THE ARTIFICIAL MEMBRANA TYMPANI.

Dr. Sapolini of Turin has written us a letter on this subject, which concludes as follows:—

"I conclude, 1. That the vulcanised india-rubber layer of Mr. Toynbee, with silver wire, is for patients and Medical men more of use, and for its easier application, and for the sure and quick improvement in hearing. 2. With this method you avoid, when perforation is large, the disturbance so excruciating if the cotton enter in the tympanic cavity. 3. The patient has no trouble at all in inquiring the right point to place the wetted cotton as Mr. Yearsley teaches us, no trouble for the quantity of the cotton, or for the degree of moisture of the same."

### GRAHAM'S SAW, IMPROPERLY CALLED "BUTCHER'S SAW."

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—I think it is universally admitted that every inventor should receive the merit of his invention. I would therefore, through the agency of your well-read Journal, beg to claim for Mr. Graham the merit of being the inventor of the surgical bow-saw, with double extending screw, and blade pointed at each end, for cutting in a curvilinear as well as in a straight direction. A saw, identical in every particular, is obtaining the designation of "Butcher's saw," and by many of the Profession thought to be a recent invention of Mr. Butcher's, perhaps from that gentleman preferring the saw in the numerous cases of excision of joints which he has performed.

The grounds on which I rest my claim are these: in 1836-7, Mr. Graham, who is now practising in Northumberland, was attending the surgical class of Professor Laurie of this city, when, in operating on the subject, the utility of the bow-saw occurred to him; he then had one made to his design, and presented it to Dr. Laurie, who has made use of it, and exhibited it to his class frequently, and in whose possession I have seen it from that time to the present. This original saw I have placed alongside one which, in London and Dublin, is named "Butcher's Saw," and without any exaggeration I say that both in principle and in outline they are one.

Permit me, then, in justice to Mr. Graham, to request liberty from the Profession to christen it for all time coming "Graham's Saw."

I am, etc.

WILLIAM B. HILLIARD,

Instrument Maker to the Royal Infirmary.

65, Renfield-street, Glasgow.

J. E. will find the information he requires in Dr. Cotton's paper in a former column.

F. G.—We know of no work exactly answering the description, but "Muller's Principles of Physics and Meteorology" might supply the information wanted. The price is 18s.

Mr. Byrne.—If a Medical man is not at home when a stranger sends for him, and that stranger then goes to another Medical man, we do not see that the first has any claim to the case. The case is of course different when the sufferer is a regular patient.

### CONSULTING GUARDIANS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—I am Surgeon to a Branch Workhouse four miles from the "Parent stem." Am I obliged to get permission of the Guardians to perform an operation, say for such a trivial thing as removal of any of the phalanges? I should state, I have attended this Institution about four years, and have performed numerous immediate operations, but not amputations. I am, etc. M.R.C.S.L. and L.S.A.

[We cannot answer this question without a copy of the regulations of the "Parent Stem."—ED.]

Mr. Hilliard.—We shall be happy to receive the descriptions.

Senex Cuique.—The review may not be quite "the thing," but it is hard to blame the author of a book because a favourable notice of it appears in a newspaper.

Asquith had better send his address, and his question shall be answered by a note.

M.D.—Dr. Fleetwood Churchill of Dublin, and Dr. J. F. Churchill, the writer on Phthisis and Phosphorus, are two very different men.

Dr. Salter, Dr. Concher, &c.—We do not insert notices of births or marriages in this Journal.

Erratum.—In the report last week of Mr. R. Taylor's observations at the Medico-Chirurgical Society, the expression "consolidate the globe," should have been "consolidate the growth."

### COOPER'S FEEDING-BOTTLE FOR INFANTS.

This bottle is the best we have seen. It is easily cleaned; the rapidity of the supply of milk is easily regulated, and no air is mixed with the milk. When infants are reared by hand it may be generally recommended.

Enquirer had better ask his question of the Secretaries of the Hall and College.

M.D. Hib.—We are glad to see such a sensible article on Medical Reform as that in the *Coleraine Chronicle*. When the question is taken up as a public one we may hope for success.

Dr. Bourchier.—The ergot of rye was used twenty years ago, in the treatment of consumption, by Dr. Robert Williams. Dr. Parola of Turin gives half a drachm of the powder daily for four or five days, and then intermits for forty-eight hours. The statement that he has cured 16 cases out of 31, is of course nonsense, but Dr. Williams's experiments might be repeated with advantage. The drug certainly diminishes the quantity of expectoration.

### COMMUNICATIONS have been received from—

Sir JOHN HALL; Mr. PRESBOTT HEWETT; Mr. TOYNBEE; Dr. G. JOHNSON; Dr. MERRIMAN; Mr. BRYANT; Dr. HALFORD; Dr. SAVAGE; Dr. RENTON, Edinburgh; Dr. LEARBE; Dr. COTTON; SECRETARY-GENERAL, BOARD OF HEALTH; Mr. WATTS; Mr. ELLICE; Mr. BARLOW; Mr. SAMSON; Mr. WALTERS; Mr. TURNER; Mr. HUNTER; REGISTRAR-GENERAL, EDINBURGH; Mr. SQUIRE; Mr. HUGHES; Mr. PARTRIDGE; Mr. HOLMES COOTE; Mr. GAMOCK; Mr. R. TAYLOR; Dr. MERI; Dr. WYTERKAD, Manchester; Dr. MARQUE, Brussels; Dr. H. F. CAMPBELL, Philadelphia; Dr. P. FRANK, Umhlati, Natal; Mr. JOHN WILSON; Dr. CRIBBEN; Mr. DICKSON; Dr. SAPOLINI, Turin; Mr. HILLIARD, Glasgow; Dr. BAINES; Mr. R. ALDERSON; Mr. HEATH; Mr. GIBB; Mr. RIVERS; Mr. RASS; Mr. SMITHER; Mr. MUNTZ; Dr. RYAN; Mr. SMITH, Southampton; Dr. CONCHER; Dr. CAMPS; Mr. HANBURY; Mr. WRIGHT; Mr. ARNOT; Mr. WHITTINGTON; Dr. TROLOPE; Mr. C. BARRETT; Dr. A. D. GULLAND; Dr. PAUL; Mr. J. HARDESTY; Dr. CUMING; Mr. J. DUNN; Mr. T. HUGHES; Dr. KEAVIN; Mr. POTTS.

## APPOINTMENTS FOR THE WEEK.

Feb. 13. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's, 2 p.m. Charing Cross, 1 p.m.

MEDICAL SOCIETY, 8 p.m.

ROYAL INSTITUTION, 3 p.m.: Professor Bloxam, "On the Chemistry of the Elements which circulate in Nature."

15. Monday.

Operations at the Royal Free Hospital, 1 p.m.; Metropolitan Free Hospital, 2 p.m.; Orthopaedic Hospital, 3 p.m.

16. Tuesday.

Operations at Guy's, 1 p.m. Westminster, 2 p.m.

PATHOLOGICAL SOCIETY, 8 p.m.

ROYAL INSTITUTION, 3 p.m.: Professor Huxley, "On Animals and Plants compared Physiologically."

17. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m. Orthopaedic Hospital, 3 p.m.

18. Thursday.

Operations at St. George's, 1 p.m.; Middlesex, 1½ p.m.; Central London Ophthalmic, 1 p.m.; London, 1½ p.m.

ROYAL SOCIETY, 8½ p.m.

LINNEAN SOCIETY, 8 p.m.

CHEMICAL SOCIETY, 8 p.m.

GROSVENOR PLACE SCHOOL MEDICAL SOCIETY, 7½ p.m.

ROYAL INSTITUTION, 3 p.m.: Professor Tyndall, "On Heat."

MIDDLESEX HOSPITAL MEDICAL SOCIETY, 8 p.m.: Dr. Farquhar Davis,

"On the Symptoms and Treatment of Hemorrhages."

MEDICAL SOCIETY OF UNIVERSITY COLLEGE, 8 p.m.: Mr. Balmaine Squire,

"On the Physics of the Earth."

MEDICAL SOCIETY OF KING'S COLLEGE: Mr. Liddon, "On Certain Displacements of the Uterus."

19. Friday.

Operations at the Moorfields Ophthalmic, 10 a.m.; Westminster Ophthalmic, 1½ p.m.; Great Northern, 2½ p.m.

ROYAL COLLEGE OF PHYSICIANS, 4 p.m.; Gulstonian Lectures—Dr. Symonds, "On Headache."

ZOOLOGICAL SOCIETY, 8 p.m. (Anniversary, 1 p.m.)

ROYAL INSTITUTION, 8½ p.m.; Mr. E. Beckett Denison, "On Some Improvements in Locks since 1851."

WESTERN MEDICAL AND SURGICAL SOCIETY, 8 p.m.: Dr. Fincham, "On Cases of Inflammatory Disease, with special reference to Treatment."

## EXPECTED OPERATIONS.

King's College Hospital.—The following operations are expected at this Hospital to-day (Saturday) at 2 o'clock:—

Removal of epulis; removal of epithelial cancer from face; removal of necrosed bone from tibia: by Mr. Ferguson.

Westminster Hospital (Tuesday, 2 p.m.)—Necrosis of antrum; stricture of urethra; fatty tumour of thigh; abscess of hip-joint.

# MR. HOOPER'S IMPROVED HYDROSTATIC BEDS, OR MATTRESSES AND CUSHIONS, FOR PLACING ON AN ORDINARY BEDSTEAD.

ANY TEMPERATURE MAY BE USED.

FOR  
ASTHENIC GANGRENE,  
BEDSORES,  
CANCER,  
CHOLERA,  
COLDNESS OF THE BODY,  
CONSUMPTIVE CASES,  
DISEASED JOINTS,  
FEVERS,  
DROPSY,  
FRACTURES,  
GOUT,

CUSHION FOR GENERAL PURPOSES.

ILLUSTRATED PROSPECTUSES,  
AND REPORTS OF CASES,  
FROM THE THREE  
PRESIDENCIES OF THE  
HON. EAST INDIA COMPANY,  
FREE BY POST.

THE FULL-LENGTH MATTRESS, OR HYDROSTATIC BED.

*The width of the Bed should be sent with the Order.*

"The comfort your Hydrostatic Beds afford can only be estimated by those that have them in use."—HENRY GILBERT, M.R.C.S., Kensington.  
"I have in several instances employed Mr. Hooper's Water Cushions and Mattresses. They have in all cases afforded great relief and comfort, and have proved much more convenient and manageable than the original Water Bed."—J. PEREIRA, M.D., Physician to the London Hospital.

GUN-SHOT WOUNDS,  
INFLAMMATION OF THE  
BOWELS,  
LASSITUDE,  
PARALYSIS,  
RHEUMATISM,  
SPASMS,  
SPINAL AFFECTIONS,  
SLOUGHING SORES,  
TYPHUS FEVER,  
ULCERATED CARTILAGES,  
AND  
ALL INVALIDS.

ORDERS BY  
TELEGRAPH, OR OTHERWISE,  
PROMPTLY ATTENDED  
TO.

**HOOPER'S WATERPROOF SHEETING** for protecting Bedding from Sloughing Sores, Incontinence of Urine, Hæmorrhage, etc.

Mr. Hooper has succeeded in manufacturing Waterproof Sheetting, at a great reduction in price, that may be washed as family linen. It is soft, odorless, and not acted on by urine, heat or cold, acids or alkalies.

**HOOPER'S URINALS**, with Valve to prevent leakage, adapted for Invalids or Railway Travellers of both sexes, for sitting, reclining, or walking; they are not affected by boiling water, and therefore may be easily kept clean.

**HOOPER'S INSPISSATED JUICE OF TARAXACUM**, prepared by dry air, can be obtained in the following forms:—

The EXTRACT: dose, a teaspoonful.

The FLUID EXTRACT: dose, a dessert-spoonful.

The LIQUOR: dose, one or two teaspoonfuls.

The LIQUOR, with CORTICAL ESSENCE OF SARSAPARILLA: dose, a dessert-spoonful.

With Brighton Seltzer Water, either of these preparations forms a pleasant draught, and with which their effects are greatly augmented.

"For emaciated constitutions, I know of no medicine equal to Hooper's Taraxacum and Sarsaparilla."—DR. JOHNSON.

For AFFECTIONS of the LIVER, KIDNEYS, JAUNDICE, INDIGESTION, CUTANEOUS AFFECTIONS, and CONSTIPATIONS, these preparations have long been prescribed by the most eminent of the Faculty with the best results. The above Extracts of Taraxacum, when mixed with water, produce a milky appearance, similar to the juice in its fresh state.

The following remarks of the Rev. A. Leapingwell show the value of Taraxacum when properly prepared:—

"So valuable a preparation as your Taraxacum can need no recommendation from me; still I feel bound to say its beneficial effects have surpassed my most sanguine expectations. My mother, who is in her 78th year, and who through the greater part of her life has been a martyr to liver complaint, appears to have had ten years added to her life by a three months' use of it. I remain yours truly, ARTHUR LEAPINGWELL, To Mr. Hooper, 7, Pall-mall East." Haydon Vicarage, Sleaford.

BRIGHTON SELTZER WATER, 4s. per doz. Other factitious Mineral Waters, at a reduction of 25 per cent.

FOR EPILEPSY.

**COTYLEDON UMBILICUS.**—The introduction of this remedial agent has proved a valuable discovery. The satisfactory accounts Mr. HOOPER has received have induced him to pay great attention to its collection and preparation. He cautions medical men against the use of worthless preparations, passed off for his, and as prepared for Mr. Salter, etc. Mr. Hooper has instructions to state, that Mr. Salter has never used any but that obtained from him. A copy of Mr. Salter's reports in the *Medical Gazette* sent free by post.

**GALUUM APARINE (HOOPER'S) FOR CUTANEOUS DISEASES, PSORIASIS, etc.**—Dr. Winn, of Finsbury-square, having published in his *Medical Gazette*, October 4th, 1851, an account of the peculiar properties of the Galium Aparine in Cutaneous Diseases, Leprosy, Psoriasis, etc., Mr. Hooper has given his attention to preparing it in various forms. Dr. Winn finds the inspissated Juice the most efficient preparation, which can be had from Mr. Hooper, or direct through the Wholesale Houses.

HOOPER, Operative Chemist, Inventor and Sole Manufacturer of Invalid Beds and Cushions, 7, Pall Mall East, and 55, Grosvenor Street, London. Laboratory, Mitcham Surrey.

**SPECIAL NOTICE.**  
To secure the advantage of this year's entry, Proposals must be lodged at the Head Office, or at any of the Society's Agencies, on or before 1st March.

**MUTUAL LIFE ASSURANCE.**  
**THE WHOLE PROFITS DIVIDED AMONGST THE ASSURED.**  
**The Scottish Equitable Life Assurance**

Society,  
Instituted 1831.  
Incorporated by special Act of Parliament.  
The Fund accumulated from the Contributions of Members exceeds ONE MILLION STERLING.  
The Annual Revenue exceeds ONE HUNDRED and SEVENTY-SIX THOUSAND POUNDS.  
The amount of existing Assurances exceeds FOUR MILLIONS AND THREE QUARTERS.  
The amount paid to the Representatives of Deceased Members is upwards of Nine Hundred Thousand Pounds, of which One Hundred and Twenty Thousand Pounds consisted of Bonus Additions.  
A Division of Profits is made every Three Years, the next Division being at 1st March, 1859.

HEAD OFFICE.  
26, St. Andrew-square, Edinburgh.  
ROBERT CHRISTIE, Manager.  
WILLIAM FINLAY, Secretary.  
LONDON OFFICE—26, POULTRY, E.C.  
ARCHD. T. RITCHIE, Agent.  
WESTERN LONDON OFFICE.  
6a, James's-street, Westbourne-terrace, W.  
CHARLES B. LEVER, Solicitor, Agent.

[ESTABLISHED 1841.]

**Medical, Invalid, and General Life**

OFFICE, 25, PAUL MALL, LONDON.  
Empowered by Special Act of Parliament.  
By the Annual Report of 1853, it appeared that the number of Policies then in force was 3434, insuring £1,337,500, and yielding an income of £55,207.

At the SIXTEENTH ANNUAL MEETING, held on 26th November, 1857, it was shown that on the 30th June last:—

The Number of Policies in force was ..	6255
The amount Insured was ..	£2,917,598 13s. 10d.
The Annual Income was ..	£125,113 3s. 8d.

Two Bonuses have been declared (in 1848 and 1853), adding nearly Two per cent. per annum on the average to sums assured, and by which a Policy of £1000 issued in 1842 on a healthy life, is now increased to £21860.

Profits divided every five years—next division in 1858.  
The Society, since its establishment, has paid claims on 776 Policies, amounting to £312,584.

Assurances are effected at home or abroad on healthy lives at as moderate rates as the most recent data will allow.

Indian Assurances at very moderate rates, and great facilities given to insurers.

Invalid lives assured on scientifically constructed tables.

Policies issued free of stamp duty, and every charge but the Premiums.

Medical men are paid a guinea for each report, and receive the same advantages as Solicitors for any business they may introduce.

Active working agents wanted for vacant places.

Prospectuses, Forms of Proposals, and every other information, may be obtained of the Secretary at the Chief Office, or on application to any of the Society's Agents in the country.

C. DOUGLAS SINGER, Secretary.

**Huxley's Half-Guinea**

**FULCRUM BELT.**—Great advantage will be found from the Diagonal Arrangement of Huxley's Fulcrum Belt, securing, in cases of Pregnancy, the chief support at the lower part of the Abdomen. It is an extremely light and elegant Article, and weighing under four ounces, is well adapted for India and warm climates. It is the only thoroughly efficacious Belt at a low price. Free by Post for 11s. 2d. To Medical Men, 9s. 2d.

Measures required—circumference at a, b, and c; depth, from a to c.

Spiral Stockings, Belts, with air-pads, for Umbilical or Inguinal Hernia and Prolapsus Uteri, 30 per cent. under the prices usually charged.

Illustrated and Priced Catalogues free by post, on application to

EDWARD HUXLEY,  
12, Old Cavendish-street (W).

**Wines from the Cape of Good Hope.—**

PORT, SHERRY, MARSALA, MADEIRA, BUCCELLAS, &c., all at 20s. per Dozen—pure and wholesome Wines, free from acidity and brandy, the produce of vineyards at the Cape of Good Hope, where the vines of Portugal and Spain are now being carefully cultivated, and have escaped the disease. Her Majesty's Government allows these Wines to be imported at half the duty, hence the low price of 20s. per dozen. Samples of any two qualities sent on receipt of twelve stamps.

The UNIVERSAL BRANDY, 15s. per Gallon, or 30s. per dozen.  
"That wine, equal to any ever produced, can be made at the Cape, all the world has acknowledged."—Times, Nov. 8th, 1856.

W. and A. GILBEY, Wine Importers, Brandy Distillers, &c., 337, Oxford-street, London, W.; three doors west of the Pantheon. Choques to be crossed to our Bankers, the Bank of England.

**For Use Medicinally, in all Diseases of**

the STOMACH, CHEST, etc., for dressing and deodorizing cancer and all foul wounds, for purifying sick chambers, for embalming of the dead, etc., Mr. JASPER ROGERS'S PATENT CARBONIZED PEAT MOSS. The various kinds of powder and lozenges are prepared solely by the Health of Towns Improvement Company. Sole Wholesale Agent, Joseph G. Thompson, Esq., 2, Adelaide-place, London-bridge, London, E.C., and 5, Long-al-square, Belfast; sold by Mr. W. L. Bird, Pharmaceutical Chemist, 42, Castle-street, East, Oxford-street, W.; Mr. J. Johnson, Chemist, 123, Upper-street, Islington, N., London; Messrs. Bewley and Evans, Dublin; and all respectable Chemists. See extracts from publications on the subject, with the preparations.

**Crosse and Blackwell, Purveyors in**

Ordinary to Her Majesty, respectfully invite attention to their PICKLES, Sauces, Tart Fruits, and other table delicacies, the whole of which are prepared with the most scrupulous attention to wholesomeness and purity. The practice of colouring pickles and tart-fruits by artificial means has been discontinued, and the whole of their manufactures are so prepared that they are not allowed to come in contact with any deleterious ingredient. A few of the articles most highly recommended are, Pickles and Tart Fruits of every description, Royal Table Sauce, Essence of Shrimps, Soho Sauce, Essence of Anchovies, Jams, Jellies, Orange Marmalade, Anchovy and Bloaters Pastes, Strasbourg and other Potted Meats, and Calf's Foot Jellies of various kinds for table use. C. and B. are also sole agents for M. Soyer's Sauces, Relish, and Aromatic Mustard; and for Carstairs' Sir Robert Peel's Sauce, and Payne's Royal Osborne Sauce. The above may be obtained of most respectable Sauce Vendors throughout the United Kingdom; and Wholesale of

CROSSE and BLACKWELL, 21, Soho-square.

**M. and R. Jewell beg to express their**

thanks for the encouragement they have received from the Medical Profession, and hope for a continuance of their favours at their Medical Glass and Bottle Warehouse, 53, Howland-street, Tottenham-court-road, where an extensive Stock is always kept on hand, at the lowest prices. Measures, Stopped Bottles, Pedestal Mortars, etc. etc. Orders punctually attended to. List of prices may be had on application.

**Kamala, a Powder obtained from the**

Capsules of Rottlera Tinctoria. Recommended as a remedy for Tape-worm; dose, half drachm to two drachms. See Medical Times and Gazette, May 2, and December 19, 1857.

ALLEN and HANBURYs have a supply of the above-named Medicine. Price to Members of the Profession, 1s. per ounce; if by post, 1s. 4d. Tincture of Kamala, dose two to three drachms, price 1s. per ounce.

London: Plough-court, Lombard-street, E. C.

Or SACCHARATED CAPSULES, approved of by the French College of Physicians, successfully administered in the Paris and London Hospitals, and acknowledged by them to be the best remedy for the cure of certain diseases. (See the "Lancet" of 6th November, 1852; "Medical Times," 10th December, 1852; a copy of which will be forwarded on application.) Price, per 100, 4s. 6d.; 50, 2s. 9d.

To be had of the Inventor, GABRIEL JOZEAU, sole French Chemist, 49, Haymarket, London, whose name is printed on the Government stamp; and of all the principal Chemists of England.

**Poultices superseded by the use of**

**MARKWICK'S PATENT SPONGIO PILINE.**

As a substitute for common poultices and fomentations, the superiority of this article is unquestionable. It is strongly recommended by the most eminent of the Faculty for its cleanliness, economy, lightness, and general efficacy, and is now used in several of the hospitals. Also, Markwick's Patent Piline, for Cholera Belts, Rheumatism, Chest Protectors, Respirators, Lumago, etc.

Sold, retail, by Chemists and Druggists, and wholesale only by GEORGE TRIMBEY, 41, Queen-street, Cheapside.

**Facta non Verba.—**

The unprecedented success of the far-famed SYDENHAM TROUSERS, invented by SAMUEL BROTHERS, 29, LUDGATE HILL, has acted as an incentive to them to use every effort to deserve the continued patronage of an intelligent public, so that they now submit their new and beautifully-fitting SYDENHAM GREAT COAT, in which is concentrated all the practical advantages of geometrical principles combined with a knowledge of the science of the human frame and its complex laws. For the SYDENHAM GREAT COAT displays the symmetry of the chest and the graceful and manly outline of the human figure, yet admits the greatest freedom of action, without discomfort or any derangement in the garment itself. In this new invention SAMUEL BROTHERS will prove their motto by deeds not words, for the SYDENHAM GREAT COAT combines the highest style of elegance and fashion with the most perfect comfort; and they therefore invite a trial, satisfied that the SYDENHAM GREAT COAT will ensure for itself an extensive patronage, as it is an elegant and economical garment.

## ORIGINAL LECTURES.

## LECTURES

ON

THE ANATOMY, INJURIES, AND DISEASES  
OF THE HEAD,

DELIVERED IN THE

*Hospital of the Royal College of Surgeons of England.*

By PRESCOTT HEWETT,

Professor of Anatomy and Surgery to the College.

## ON FRACTURES OF THE SKULL.

## LECTURE II.

DAUGHTER as are the cases of fracture which we were considering in our last lecture, still more dangerous are those cases in which the injury of the bone belongs to that variety known as the punctured fracture. Let us bear clearly in mind that in all fractures of this nature, produced by the corner of a brick, a sharp stone, a nail, the end of a poker, and, in fact, any pointed instrument, the injury of the outer part of the bone does not correspond in extent to that of the inner part; the outer plate is driven in or perforated, the inner one is cracked, and extensively splintered, the sharp splinters being more or less thrust down upon the dura-mater, which they are very apt, indeed, to wound.

Such punctured fractures, if left to themselves, almost invariably give rise to intra-cranial inflammation and suppuration. In the broader fractures with depression, we have already seen that the patient has some chance of escaping internal mischief when the fragments remain; but in the punctured fractures you will find that even this chance is very much lessened. Hence the rule, now so common among Surgeons, that the trephine is at once to be applied to punctured fractures with depression and without symptoms.

I have said that the punctured fractures, when left to themselves, almost invariably give rise, sooner or later, to intra-cranial mischief of a most serious nature. Here are two examples admirably illustrative of the alarming symptoms arising from the projecting fragments when left, and of the use of the trephine in such cases.

A boy, aged 15, was admitted into St. George's Hospital, under the care of the late Mr. Babington, in October 1842, with a small punctured wound, leading down to a fracture with depression. The injury was on the left side, a little below the lambdoid suture, and about two inches from the ear. The lad complained of intense pain in the head, and of giddiness; the skin was very hot and feverish; the pulse quick, but not sharp. This was his history:—Five days before he came to the Hospital he had been struck on the head by a stone, which another boy had thrown at him. He was but slightly stunned, but lost a good deal of blood; he then went to a chemist, who strapped the wound over. For two days he felt very well, and went about his business as usual. On the evening of the third day, however, he was attacked with great pain in the head and shiverings, and was very restless during the night. These symptoms had continued ever since, and so great was the pain in the head, that he could hardly keep it up; and when walking to the Hospital he felt very giddy. At a consultation of the Surgeons it was decided that the trephine should be at once applied. The wound was enlarged, and the crown of a trephine applied just over the fracture, which was a punctured one; the depressed portion of bone was removed; the internal table was splintered and fractured to a much greater extent than the external one; the dura-mater corresponding to the depressed bone looked as if it had been slightly wounded, but this was not satisfactorily made out. The patient was purged, and put upon low diet. By the following day all the cerebral symptoms were much relieved, and so well did this lad go on after the operation, that he never was even bled once, and required no mercury, save as a purge occasionally. In about a month the wound was nearly healed, and he left the Hospital.

The following case is, however, even more strongly marked:—

A boy (a) was admitted into University College Hospital

on the sixteenth day after having been struck on the side of the head by a large nail, projecting from a door, which had fallen on him. No symptoms of any kind had occurred until the eleventh day after the accident, when he became dull, and lost his appetite. On the sixteenth day, that of his admission into the Hospital, he had suddenly become drowsy and delirious, but still answered questions when spoken to, and complained of pain in the head. The pupils were dilated; the skin hot, and the pulse quick. On examination, a small round opening, from which some fetid pus exuded, was discovered over the right parietal eminence. Through this opening, just large enough to admit a probe, some rough bone was felt. Mr. Samuel Cooper immediately trephined the boy, removing a circle of bone, including the small opening. The inner table was splintered to some extent; the dura-mater was thickened and inflamed. After the operation, this boy recovered without a single bad symptom.

But it occasionally happens, and especially in these punctured fractures, that a fragment of bone is seen sticking into the brain; in fact, brain-substance may be seen oozing out of the small opening around the depressed piece of bone.

Such being the case, is this at once to put an end to all our operative proceedings? Are we to defer the operation for some days? Are we to leave the bone where it is?

I think not. Still bearing in mind that every case of injury of the head, of whatsoever kind, may present special features demanding a special treatment, I deem it, nevertheless, to be the duty of the Surgeon in the majority of instances to make at least an effort to get away every fragment of bone thus seen to be sticking in the brain.

Every effort of this kind should, however, be characterised by extreme caution, and the Surgeon must ever recollect that the greatest care, the greatest nicety of handling is here required of him.

We make the attempt, then, with all due care—and it may so happen that the fragment comes away easily and readily; but it may happen, as so graphically described by Colles, that “if we attempt to seize the depressed fragment, the first touch of the forceps sinks it more deeply into the brain; portions of the brain, from the softness of its texture, rise up, and conceal the bone both from our sight and from our touch;”—here, no doubt, the wisest course is to desist from all further endeavours. And far be it from me to recommend any Surgeon to undertake any of those curious and daring investigations which have been carried on, we are told, through the length and breadth of the brain, in search of some fragment or foreign body lodged within its substance.

Not being able to extract the fragment without the risk of doing great mischief, we leave it. Adhesive inflammation may take place, and harden the brain around it, so that in a few days we may perhaps be more successful; or the fragment may in the course of time either be thrown off, or else scarred over.

A girl, aged 12, was admitted into St. George's Hospital, in August 1841, under the care of Mr. Keate, with a wound on the top of the head, not larger than a quarter of an inch in length, and lying over the meeting of the coronal and sagittal sutures. A probe being introduced, passed down into some soft matter; the pulsations of the brain were evident, and soon afterwards portions of brain were protruded. There were no symptoms whatsoever. The patient answered all questions perfectly well, and stated that a piece of iron had been thrown at her, and struck her on the head. Mr. Keate at once cut down upon the part, and a portion of hair was discovered driven deep down; this was removed, and then a pointed fragment of bone came into view; it appeared loose, but could not be removed with the forceps; it was therefore left. Some inflammatory symptoms followed; the patient was then bled, and soon brought under the influence of mercury, and by the eighth day all alarming symptoms had subsided. On the fourteenth day, the House-Surgeon, Mr. Henry Lee, removed with the forceps two small pieces of bone and several hairs, which were lodged at least half an inch below the level of the skin. Save an attack of erysipelas, which came on a few days afterwards, the patient went on uninterruptedly well, and when she was discharged from the Hospital the wound was perfectly healed.

Such was the plan adopted by Mr. Keate in this case, and such, too, was the plan adopted by Sir Philip Crampton in Mr. Brougham's case. In both instances, you will observe that an attempt was at once made to get out the fragments.

(a) *Erichsen's Surgery*, p. 263.

But one of Colles's practical precepts is that, in such cases as these, all interference should be postponed for a few days, in order that the cerebral substance around the fragment may have time to become consolidated.

Now, I cannot help thinking that more mischief is likely to accrue from the bone being left, even for a few days, sticking in the brain, than from the well-directed efforts of a cautious Surgeon. The case is, indeed, one of extreme danger; if left to itself, the bone may produce irreparable mischief; in our attempt at removal we, too, may bring about that very mischief which we were so anxious to avoid. It is, in truth, a choice between two most serious evils, and every Surgeon must decide for himself, according to the circumstances of the case.

Closely allied to these punctured fractures is that form of fracture so much dwelt upon by Mr. Guthrie, where a clean cut exists in the outer parts of the bone, with a more or less extensive splintering and depression of the inner plate. Such fractures may be more common in military practice; but they, or something very like them, are not uncommonly met with in civil practice; the cause of the injury being in this case, as I have already said, slates, sharp stones, broken bottles, etc.

In these cases, having ascertained that there is a clean cut through the outer parts of the skull, our next point is to ascertain the state of the inner plate. For this purpose, Mr. Guthrie advises that "a blunt or flat-ended probe should in such cases be carefully passed into the wound, and being gently pressed against one of the cut edges of the bone, its thickness may be measured, and the presence or absence of the inner table may thus be ascertained." To this, however, the following objections are put by Mr. Benjamin Philipps.<sup>(b)</sup> "Supposing the interval between the two tables to be considerable, how is the surgeon to feel secure that it was not the normal condition in this particular case? And would he be justified in applying the trephine because he found a greater than usual space between the two tables? Besides, if even there were fracture of the inner table with depression, is it sure that the probe would detect it?"

In these objections of Mr. Philipps's there is doubtless some reason; no doubt there is at times great difficulty in exactly ascertaining the state of the inner plate of the bone—still the difficulties are not insuperable in the majority of cases. Instead of trying to measure the thickness of the bone—bearing in mind how the inner plate splinters, let us try to carry the probe sideways, as soon as we have got through the cut edges of the bone, and if we find that we can thus pass the probe first under the outer plate, and then feel the inner plate some distance deeper, we may be sure that the two plates are separated from each other, and that the inner one is broken and depressed.

Thus far we have seen that operative surgery often is of essential service in depressed fractures of the vault of the skull: but, thus far, we have been dealing only with those cases in which primary brain symptoms were either absent, or but very slightly marked. This is the bright side of the picture. Let the fracture co-exist with primary brain symptoms, and the case at once becomes a much more complicated, a much more dangerous one.

In these depressed fractures with primary brain symptoms, again must we ask ourselves this question. Being clear as to the existence of a depressed fracture, are we at once to resort to an operation in all cases accompanied by primary brain symptoms? Here, again, we find this question giving rise to the question of "wound, or no wound, leading down to the bone;" and here, again, we find the answer given to this question modifying the practice of our best masters.

1st. There is no wound leading down to the depressed bone. Then, let us carefully avoid making one, if the symptoms are such as not to call imperatively for the use of the trephine. Not being very urgent, the symptoms may perhaps be dependent upon concussion of the brain, or upon some slight pressure, either by blood or bone; and such symptoms, it is well known, may, and frequently do, pass off under the influence of judicious treatment. We may postpone the operation, and see what we can do with our other remedial measures before resorting to the trephine. But, if the symptoms are urgent, if they indicate decided pressure upon the brain, then operative interference becomes necessary: a wound must be made, the

depressed bone must be freely laid bare, and either elevated or removed. And the sooner this is done the better.

2ndly. There is a wound leading down to the depressed bone. If we think it necessary to remove the bone, where the bone alone is injured, all the greater necessity will there be for our removing the bone when cerebral symptoms exist. And, having a wound already made, we had better operate at once, even if the symptoms are slight, as they may be altogether dependent upon the depressed bone.

If the cerebral disturbance be slight, we may naturally hope that the structure of the brain itself is scarcely if at all injured, and that the operation will be successful.

A lad, 13 years old, was admitted into St. George's Hospital, under the care of Mr. Pollock, in September 1854, with a small contused wound over the right eyebrow, leading down to a fracture with marked depression. There was partial insensibility, but no stertor, and no loss of power over the limbs; he put out his tongue when ordered to do so, but would not answer any questions; was constantly rolling about the bed; occasionally noisy, and called out lustily when the wound was examined. Blood was effused in the right eyelids, as well as under the ocular conjunctiva; the eyeball was very prominent, evidently from the blood in the cellular tissue of the orbit. There were marks of dried blood both about the left nostril and in the left ear. The account given by those who brought this boy, was that he had been sent the previous evening into a field to drive in some horses, by one of which it was thought that he had been kicked on the head, as he was found some time afterwards lying on the grass insensible, and bleeding freely from the wound over the eyebrow. When Mr. Pollock saw the boy a short time after his admission, the symptoms were somewhat more marked, and it was determined, in consultation with Mr. Tatum, to operate at once. Free incisions were made in connexion with the wound, which laid bare a considerable surface of depressed bone: the fracture was a comminuted one, and the fragments tightly jammed in. A portion of sound bone was therefore removed with the trephine, and one of the fragments was easily taken away; but it was not until a part of the projecting bone had been cut off with the nippers that the lower fragment, which was driven down into the orbit, could be got at, and so firmly was this fragment found to be wedged in, that it was with great difficulty even partially raised: several smaller pieces of bone were then removed. The dura-mater which was thus exposed to the extent of about half a square inch, seemed to be uninjured; from the appearances which it presented it was, however, thought that blood had been effused under it. The operation was not followed by any immediate relief; the cerebral symptoms still continued unabated; the pulse was sharp and quick, with great heat of skin, and under these circumstances it was thought advisable to give the patient some small doses of mercury, which were, however, discontinued on the following day, as he appeared to be very much reduced. Some strong beef-tea was now ordered. For three or four days he remained much in the same state; at times very noisy and restless, but nevertheless somewhat more conscious. All medicines were carefully avoided, and he was put upon fish diet, which was increased to ordinary diet on the eighth day, as he continued gradually improving. The eyeball still remained very prominent, with a good deal of chemosis at the lower part, so much so indeed that the lid was everted. Subsequently to this nothing occurred to interrupt the boy's convalescence; the protrusion of the eyeball became less marked; the wound scarred over; and he was discharged from the Hospital, sound in mind and body, in the month of December.

In the case which I have just brought before your notice, the brain symptoms proved to be independent of the depressed bone, and they might perhaps have been relieved without an operation. But, as it sometimes happens that such symptoms are altogether dependent upon the state of the fracture in these slighter cases of cerebral disturbance, there is, I think, a clear indication for an immediate operation, whenever there is a wound. It is then the existence of a wound which in these cases leads us to operate at once, and it is in such cases that the operation will not unfrequently be attended with complete success.

But how seldom will success crown our efforts in those cases in which the cerebral symptoms are urgent, where compression of the brain is decided, and strongly marked!

True it is that operative interference is all the more

(b) *Med. Gazette*, vol. xxxiii. p. 106.

urgently called for in such cases, but equally true is it that an operation undertaken under such circumstances will seldom—very seldom—be attended with success. The records of every hospital easily explain this. There it is shown how rarely it happens that the brain symptoms in these cases are dependent upon the bone alone. And let me add that it has never yet fallen to my lot to meet with a case of cerebral disturbance of a formidable and urgent character, in which such symptoms were wholly dependent upon depressed bone. In every case which I have seen with these symptoms strongly marked, there was also some extensive extravasation of blood, or some serious lesion of the brain substance itself.

Being perfectly aware of the serious and all but fatal complications which so frequently co-exist with a depressed fracture, still it is our duty not to give up the case as hopeless. Let us not forget that there are many cases on record by which it has been clearly proved that cerebral symptoms, even of a very urgent nature, may, after all, be altogether dependent upon the depressed bone; cases in which the symptoms have persisted so long as the bone remained depressed, and been relieved only by its removal. Such a case as Cline's, for instance, in which the symptoms continued unabated for the extraordinary period of thirteen months, and were then relieved by the removal of the bone, at once disproves the opinion that it is useless to resort to an operation in cases of severe cerebral symptoms with fracture and depression. There can be no doubt that it is our duty to operate at once in such cases, notwithstanding that the chances are so much against us.

In a compound fracture with depression, the indriving of a piece of bone along the course of one of the large venous sinuses, the longitudinal or the lateral, may give rise to hæmorrhage of an alarming character. But, however alarming such bleeding may, at first sight, be, it is generally said that the danger is more apparent than real. In our different works on Surgery may be found a goodly number of cases of wounds both of the superior longitudinal sinus, and of the lateral sinuses, which did perfectly well, notwithstanding the loss of a large amount of blood. The bleeding, in such cases, however profuse, is represented as being most easily controlled; so much so, indeed, that M. Chassaignac states that he had not been able to find on record a single instance of fatal hæmorrhage from a sinus thus wounded.

Here is a case, however, in which bleeding from a wound of the left lateral sinus did lead to the death of the patient.

A man, aged 51, remarkably stout and large-framed, was admitted into St. George's Hospital, under the care of Mr. Keate, in August 1847, perfectly blanched from bleeding of so profuse a character that his waistcoat, shirt, and other clothes were completely saturated with blood. This bleeding was connected with a compound fracture of the skull, situated in the course of the left lateral sinus, and about two inches from the ear. The poor fellow had, it appeared, fallen off a scaffold, upwards of twenty feet high, and struck his head against the top of some iron railings, one of the points of which had gone through the bones. The patient was perfectly sensible, and had not been even stunned at the time of the accident. The bleeding had all but stopped when he arrived at the hospital; but it was stated by those who came with him that he could not have lost less than close upon four pints of blood. The fracture itself proved to be a comminuted one, with several loose splinters; one fragment was bent outwards so as to be standing up above the level of the surrounding bone, in which position it was fixed by the fracture being only partial on one of its sides; no fragment could be detected driven down towards the brain, the pulsations of which could be distinctly felt at the bottom of the wound. Mr. Keate thought it advisable to postpone interfering with the fragments. Suppuration of a foul character soon set in; the wound put on an unhealthy, sloughing appearance, and, on the eighth day after the accident, hæmorrhage of a venous character suddenly made its appearance; it was easily stopped, but it recurred slightly on the following day and then ceased. During the whole of this time there were no cerebral symptoms of any kind. Generous diet was ordered as the patient was low, and the wound very foul and sloughy. He appeared to be going on perfectly well, and was daily gaining strength, when bleeding again made its appearance on the eighteenth day after the accident, and from this day it kept constantly recurring, at times stopping, and then coming on again, notwithstanding the numerous and various

means which were used to check it. And thus matters went on for some fortnight, when the patient sank, exhausted from the constant draining of blood, having lived nearly five weeks after the accident. This preparation (c), belonging to the museum of St. George's Hospital, shows the perforation at the back part of the skull communicating directly with the left lateral sinus. The sinus itself presented no traces of inflammation, and it contained a small coagulum only. The brain was blanched, and so too was every part of the body.

In the case which I have just mentioned, it is right to notice that, after the first violent bleeding, no hæmorrhage took place until the wound had put on an unhealthy aspect. The recurrence of the bleeding was due to the sloughing of the wound; no attempts at repair were made either by the surrounding parts, or by the walls of the sinus, the hole in which remained perfectly patent, and gaping; the sinus itself did not become blocked up by fibrinous deposits; the blood circulating through this channel found therefore a ready means of escape—in fact, the man died of repeated attacks of secondary hæmorrhage.

It is curious to notice how lightly injuries of these large venous sinuses are spoken of by many Surgeons of great repute. Indeed so lightly was an opening into these sinuses thought of in former days that Pott did not hesitate, in a case where the superior longitudinal sinus had been laid bare, to open it with a lancet, in order to relieve more immediately the vessels of the brain—dealing, in fact, with this sinus, as he would have done with a common vein, thinking only of the possible difficulty of stopping the flow of blood, and little dreaming of any ulterior mischief which might arise from his proceedings.

And how seldom, in fact, do we find any allusion made, even in our most recent authors on injuries of the head, to the mischievous consequences which may arise from a diseased action being set up in these sinuses, either from an injury implicating the sinus itself, or from an injury done to the bones in the immediate neighbourhood of the sinus. Recent investigations prove, however, that, under such circumstances, fibrinous deposits and suppuration, with all its secondary consequences, may take place within these sinuses.

In examining the body of a patient of Mr. Cæsar Hawkins', in March, 1852, I found the channel of the left lateral sinus completely blocked up, from its mastoid portion down to the jugular vein, by a very firm coagulum of a rusty brown colour, and adherent throughout to the inner coat of the sinus. This fibrinous deposit, evidently of several days' standing, was connected with a slight fissure implicating a part of the bone in which the sinus is lodged, but no trace of actual injury could be detected in the coats of the sinus itself. The fracture had been caused by the patient falling with the back of his head against a stone pavement. Symptoms of diffuse inflammation of the membranes soon made their appearance, and he died eight days after the accident. But, had this patient lived longer, suppuration within this sinus would, in all probability, have ensued.

A man, aged 37, was admitted, drunk, into St. George's Hospital, under the care of Mr. Cæsar Hawkins, in July 1835, with a small scalp wound, exposing the bone above and a little behind the left ear. The injury had been caused by a fall against the edge of a stone step, during a scuffle in which he was engaged with one of his companions; and it appeared that whilst still on the ground he had had an attack of an epileptic character. With the exception of some slight giddiness, for a day or two, everything went on very well: the wound was healing, and he was made an out-patient after some eight or ten days. But he was re-admitted into the Hospital about three weeks afterwards, with great pain in the head, and a good deal of discharge, of a puriform character, from the meatus, accompanied by fever and a low pulse. The pain in the head had come on shortly after he left the Hospital, and the discharge had made its appearance suddenly on the day previous to his re-admission, as if "something had burst inside his head." The wound was not quite healed, and the bone was still exposed. Two days afterwards, he had some distinct rigors, accompanied by great restlessness, and an increased discharge from the ear. Then came other rigors, with typhoid symptoms and profuse perspirations. These symptoms continued, with slight intermissions, for some days; but there was no paralysis, neither was there any affection of the mind; still it was thought advisable to apply a

trepine over the exposed bone. No matter was found between the bone and the dura-mater, the surface of which looked quite healthy, and the inner surface of the bone was still living and healthy. No relief was afforded by the operation, and the patient died three days afterwards. A lineary fracture was traced across the temporal bone, to the junction with the sphenoid. The dura-mater (d), where exposed by the trephine, was quite healthy, but, within a quarter of an inch of the opening, both surfaces of the tentorium were covered with lymph and pus, which appeared to have commenced in the lateral sinus. The sinus was blocked up with coagulum, and lymph and pus; but two small openings existed on its outer surface, and one on its inner surface, just below the tentorium. From the latter pus escaped, so as to cover the cerebellum to a small extent, its further passage being bounded by lymph. The external openings, towards the bone, were also surrounded by lymph; but the matter from the sinus appeared to have escaped through the linear fracture into the tympanum, as well as into the external meatus, giving rise to the discharge from the ear noticed during life.

(To be continued.)

## ORIGINAL COMMUNICATIONS.

### CLINICAL EXPERIENCE ON THE NATURE AND TREATMENT OF UTERINE DEVIATIONS,

MORE ESPECIALLY OF PROLAPSUS.

By HENRY SAVAGE, M.D. Lond.  
Senior Physician to the Samaritan Hospital.

(Continued from page 161.)

*Marshall Hall's Operation, fig. 7.*—This operation succeeds by keeping the uterus from entering the vagina, which it seeks to do by narrowing its calibre and restoring its tone and elasticity. But it must, at the same time, do away with the mechanical disadvantages above referred to, by bringing the line of pressure across the vagina instead of in a line with it, or it must inevitably fail.

FIG. 7.

A strip of vaginal mucous membrane, an inch and a half wide, and running its entire length, is removed from the front of the prolapsus. The long wound is brought together laterally by interrupted suture and the prolapsus reduced.

Diefenbach removed a portion of mucous membrane the size and shape of half an egg from both sides of the prolapsus,

(d) Catalogue of Mr. Hawkins' Museum, I. a 17.

and having applied the sutures, and replaced the tumour, in some cases he also drew down, by *Museux's* forceps, another fold which he removed with scissors. This wound he left without sutures.

Ireland, Velpeau, Berard, and Bellini adopted a modification of Hall's plan. The plans of Dr. Every Kennedy (Letter to Sir B. Brodie, *Lancet*, 1839) with the actual cautery—of Mr. B. Phillips (*London Med. Gazette*, 1839) with fuming nitric acid—that of Degrange, with *serres fins*, &c., are the same in principle.

In a case admitted into the Samaritan Hospital two years ago, where the prolapsus was chiefly of the bladder, I removed from the most prominent part of the tumour a piece of mucous membrane, the size of the bowl of a large table-spoon. The denuded surface bled rather freely, and two small vessels had to be secured. The wound was brought together laterally by interrupted suture, and the tumour reduced. She was kept in bed not quite three weeks, and allowed to leave the Hospital shortly afterwards, wearing a small Zwanke. She was watched for some months as an out-patient, and I have lately ascertained that she laid aside the pessary upwards of six months ago, and has had no return of the disease since the operation.

I now come to Fricke's operation, which relieves solely by preventing the escape of the uterus out of the vulva. This operation, even when modified, as described below, in my opinion, is desirable only in those cases which have proved rebellious to a fair trial of the methods above described, where also the perinæum is deficient, or has lost its resistance by long-continued distension. Every day's experience shows the error of the assertion that a weak or deficient perinæum must necessarily sooner or later entail prolapsus of the uterus; although it is quite certain that the moderate contraction of the lower end of the vagina and the restoration of the vaginal perineal angle by means of a plastic operation are essential to the success of every procedure on Fricke's principle.

FIG. 8.

*Fricke's method (8).*—The operator transfixes the labium with a sharp pointed bistoury, so as to remove a slip about the width of the finger, commencing about two fingers' breadth from the upper commissure, and joining a similar slip from the opposite labium, at an angle about a finger's breadth behind the fourchette. Bleeding vessels are secured by torsion, the exposed surfaces placed face to face, and secured by ten or twelve points of ordinary interrupted suture (*Annalen der Chirurgischen des Allgemein Krankenhaus in Hamburg*, 1833). Sponge was introduced into the vagina before bringing the wound together, to prevent the prolapsus interfering with the adhesive process. Fricke is said to have cured three out of four; and I notice that Professor Fergusson, of King's College, has reverted to this, after having operated in another way to be presently mentioned; nevertheless I feel convinced Fricke's plan must fail in the long run. A perinæum thus

formed has no vaginal angle, and can never long stand the abdominal strain, propagated as before stated under every mechanical aggravation through the uterus lying in the inverted hollow vaginal cone.

The same objection appears to have struck Professor Geddings, of the Medical College of South Carolina, whose interesting monograph has furnished much of the foregoing historical detail.

FIG. 9.

**Geddings' Method.**—Having marked off on the labia, by a sweep with a sharp scalpel carried from one side to the other behind the commissure, a slip the size of that in Fricke's operation, he proceeds to remove it by dissection, continuing so as to remove also a slip of mucous membrane from the vagina of a corresponding horse-shoe shape, and similar in this respect to the slip recently described by Mr. Brown as the peculiarity of his operations. Geddings says, "I have never found it necessary to use more than five interrupted sutures. I also use the quills. (Fricke's sutures remained for ten or twelve days.) I never leave either quills or sutures after the tenth day, and I use no sponge."

His first case was in July, 1839. His monograph containing his remaining cases, which appeared in 1840, anticipates, in respect to the operation, sutures, subsequent treatment, &c., everything of importance, which has been done since. All his cases completely succeeded.

Mr. Brown's first case was in 1853.

FIG. 10.

He removes a horse-shoe slip of mucous membrane, but no part of the labium. The sutures and subsequent treatment exactly resemble the same as described in 1839 by Geddings. Mr. Brown thinks the removal also of a square piece of

mucous membrane, as indicated in the cut, affords additional security when the bladder is much prolapsed.

Fricke's operation I never adopted. I have operated in twenty-one cases, exclusive of the case above. After trying both Geddings's and Brown's plan, which I thought were not without objection, I came to a modification of my own.

FIG. 11.

I mark off on the vulva and vagina all the redundant skin, and as much of the latter as will promise most subsequent contraction, and then dissect, so as to remove all the skin so circumscribed, and with it the entire thickness of the vagina, using quills, interrupted sutures, exactly as in Geddings's cases. The result has always been an efficiently firm perineum, a good vaginal perineal angle, and enough subsequent vaginal contraction, without excessive diminution of the vaginal aperture.

FIG. 12.

Perineum immediately after operation.

FIG. 13.

Perinæum after recovery—uterus just apparent behind the aperture.

A glance at a foregoing cut (fig. 3), of the section of the pelvis, made with every care to ensure correctness, will show what is meant by vaginal angle. The following selection of cases will prove it to be one of the chief preventatives to the return of the prolapsus. Two of these cases (the only unsuccessful ones) illustrate in a very striking manner that when the uterus succeeds in turning the corner so as to bear entirely upon the vaginal aperture, it is sure to bore its way out, and the operation is altogether a failure.

The true perinæum can be felt as a firm, resisting, slightly elastic ring, the *vaginal ring*, where the vagina terminates at its opening in the perineal fasciæ, it is at once felt by the finger, where these unite at a horizontal line leading from one tuber ischii to the other. The Peroneo vaginal angle of the vagina is where the tegumentary perinæum begins. *The object of the operator is to prevent the new perinæum from having to sustain all the pressure.*

The following have been selected from my twenty-two cases, and details given with a view of illustrating what such an amount of experience may be worth, in deciding upon the value of a method which has of late been so generally and unequivocally recommended in one quarter, and as decidedly discountenanced, if not condemned, in another equally respectable.

*Case 1.*—An old Frenchwoman, 75, widow the last twenty years; thin, haggard, feeble. A very large prolapsus pendent nearly a foot out of the vulva. Womb large, excoriated, here and there deeply ulcerated; cervix large, indurated; os large, open, cracked into three deep fissures, turgid, injected; mucous membrane of vagina in coriaceous flakes; vagina distended into a tough, leathery, inelastic bag, having by nearly twenty years of distension entirely lost its contractile power. No signs of laceration of perinæum, vaginal ring scarcely perceptible. Both labiæ loose, flaccid, redundant. The prolapsus contained apparently intestines and bladder besides the uterus. Curved male catheter followed direction of prolapsus. On the whole nothing could be more strikingly pitiable and helpless than the state of this poor old woman, going about with her "chute" badly supported by an ordinary napkin. Said this had been her condition for the last fifteen years, in spite of the various means adopted to relieve her. Not clearly apparent by her account that the prolapsus ever had been properly reduced. She was admitted.

It was thought advisable to look after her general health for a fortnight before the operation. The operation was performed according to Plan 9.

The quills removed on the fifth day, the sutures on the seventh. Adhesion throughout by first intention. She was not allowed to get up until three weeks after the operation.

Opium was found to disagree; not more than two grains given. Sphincter ani not divided. Dressing-pledgets of water, cold or warm, according to circumstances. Careful nourishment. She preferred milk, beef-tea, soups, etc. Wine and stimulants, except very sparingly, and not every day, found to disagree. Scrupulous care taken to syringe out vagina, and keep the parts clean.

Condition at the end of six weeks, when allowed to leave her bed:—No prolapsus visible; uterus hardly within reach of the finger, but a knuckle of vagina down to within half an inch of vaginal aperture. Adhesion perfect throughout. Patient much stronger, and infinitely more comfortable than before the operation.

A week after getting about, the knuckle of vagina slightly protruded. She thought she was "mal coussue." I did not consider it advisable to adopt her repeated suggestion to have the vaginal aperture entirely closed.

Six months afterwards I had an opportunity of examining this case. The vagina had not in the least recovered its tone. The finger as soon as it entered the vagina came in contact with the uterus, and numerous folds of vagina, one of which projected about half an inch from the vaginal orifice. The new perinæum was firm and sound. A belt and under pad easily retained the insignificant vaginal protrusion when reduced.

To be continued.)

## DRAINAGE AND WATER SUPPLY IN CONNEXION WITH THE PUBLIC HEALTH.

By JOHN SNOW, M.D.

(Concluded from page 163)

THE material among the emanations from drains and sewers which is supposed by many persons to be most active in promoting zymotic disease is sulphuretted hydrogen gas; but it must be acknowledged that the chemist never catches any disease from this gas, when liberated in his laboratory; and that invalids drink a solution of it at Harrowgate and other places, without acquiring any tendency to zymotic disease, although the gas is undoubtedly absorbed into the blood. An instance occurred lately of this gas being set free on a very large scale, without its doing any injury to health. It is as follows:—

"At a certain point in Westerdale Head (North Riding) the process of jet-mining has been carried on for some time past, and a few weeks since it was observed that the heaps of shale excavated or turned over by the miners were giving out much smoke, and the smoke was accompanied by a noisome smell or stench. This smell, which is that of the sulphuretted hydrogen gas liberated from the decomposing alum shale, has been perceived at points not less than seven or eight miles, or even more, from the point of its origin; and every room in houses three or four miles distant is most offensively penetrated by it at all times of the day and night. The burning heap is of large dimensions; many thousands of tons of the displaced shale lie in heaps more or less continuous. . . . It had been surmised that a mischievous effect on the health of the neighbourhood would be produced; but so far beyond the nauseous, suffocating fumes, which annoy everybody for miles in the direction of the wind from the burning heap, no harm seems to have been done; and it may be hoped, therefore, that none will now arise. Even among the inhabitants of the houses in the neighbourhood of the place no worse consequence than the annoyance from the almost intolerable stench has so far arisen."—*Times*, 7th January, 1856.

It is quite true that sulphuretted hydrogen will cause sudden death when breathed in a too concentrated state, but no argument ought to be adduced from this circumstance with regard to its causing illness, for carbonic acid gas will also cause sudden death, although it is a normal constituent of the atmosphere.

I have in former papers, in this Journal and elsewhere, been able to point out the very close connection which exists between the mortality of cholera and the contamination of the drinking water, by the contents of sewers and cesspools. It has very frequently been observed, that cholera was most fatal in situations where the ordinary mortality was highest; and, taking both these circumstances into consideration, there was reason to presume that the kind of pollution of the water mentioned above increased the ordinary mortality, at times when the cholera was not present. I am now able to show, from a set of statistics compiled and calculated from the Quarterly Reports of the Registrar-General, that this is the case. That part of this metropolis which is situated in the county of Surrey is supplied with water by two companies

—the Lambeth Company, and the Southwark and Vauxhall Company. No other company supplies any portion of the metropolitan part of Surrey, except a very small portion of Rotherhithe, which is supplied by the Kent Waterworks Company.

The estimated population supplied by the Lambeth Company in 1854 was 166,906, and that supplied by the Southwark and Vauxhall Company 268,171. These numbers leave about 65,000 persons who were probably supplied by pump-wells, and lived chiefly in the more suburban districts, as Clapham, Wandsworth, Camberwell, and Norwood. The Lambeth Water Company, which supplied about one-third of the population of the metropolitan part of Surrey, obtained their water from the Thames in London, near the Hungerford Suspension Bridge, until January, 1852, when they moved their water-works to Thames Ditton, beyond the influence of the sewers of London. The Southwark and Vauxhall Company, which supplied more than half the population of that part of London which is situated in the county of Surrey, continued to obtain water from the Thames, between Vauxhall and Battersea, until July 22, 1855, when they obtained their supply from near the village of Hampton. I have shown, in the Table No. 2, the mortality in that portion of London which is in the county of Surrey, in every quarter of each year, commencing with 1850, and extending to June 1853, shortly after which period the cholera made its appearance. I have omitted the latter part of 1853 and the year 1854 from the table, as the cholera was present, and the mortality from this disease in this part of London has already undergone a very extensive and minute inquiry, extending to particular cases. Moreover, I do not wish on this occasion to inquire into the effect of water-supply on cholera, so much as on other diseases. The statement of the mortality in the table is, therefore, resumed at the beginning of 1855, and continued till the end of 1857. Throughout the table the mortality of the remainder of the metropolis during each year, and each quarter of a year, is shown side by side with that part of it which is situated in the county of Surrey.

TABLE II.—Mortality of the Metropolitan part of Surrey compared with that of the rest of the Metropolis.  
METROPOLITAN PART OF SURREY—Population in 1851, 482,436.

	Deaths.	Deaths per 1000 of Population of 1857.
Quarter ending March 1850 ... ..	2,854	5.9
Quarter ending June 1850 ... ..	2,404	4.9
Quarter ending September 1850 ... ..	2,551	5.2
Quarter ending December 1850 ... ..	2,901	6.0
Year 1850	10,710	22.2
Quarter ending March 1851 ... ..	3,206	6.6
Quarter ending June 1851 ... ..	3,826	5.8

Year 1857	48,037	25.5

It will be observed that in the years 1850 and 1851 the mortality of the metropolitan part of Surrey was considerably above that of the rest of the metropolis, being 1.8 per 1,000 above it in 1850, and 1.5 above it in 1851. In 1852, when a part of the water-supply of that part of London had been improved, the mortality still remained greater than that of the rest of the metropolis, but to a less extent than in the two previous years, only exceeding it by 1.2 per thousand. In the first half of 1853, the mortality of the metropolitan part of Surrey exceeded that of the rest of London by only decimal 4 per 1,000, or at the rate of decimal 8 per 1,000 per annum. When the account of the mortality is resumed in 1855, after the cholera had passed away, it will be observed that the mortality of the metropolitan part of Surrey is still above that of the rest of London, in the two first quarters of the year; but on the 22nd of July, the Southwark and Vauxhall Company changed their source of supply from Battersea Fields to a point near Hampton, beyond the reach of the contents of the London sewers; then the whole of the metropolitan part of Surrey had an improved supply of water, and then, for the first time within the period of my inquiries, the mortality of this division of London falls, in that very quarter of the year, below the mortality of the remainder of the town. It remained below it in the last quarter of 1855, and also in the years 1856 and 1857, taking the mortality by the year together; and there are only two separate quarters in which the mortality of the Surrey Division of London rose a very little above that of the rest of the metropolis. I have not made any corrections for increase of population, because that of the metropolitan part of Surrey increased, from 1841 to 1851, exactly in the same ratio as that of the rest of London, and therefore the relative mortality of the respective divisions would have remained the same in the table, if the correction had been made.

The Chelsea Water Company removed their source of supply

at the end of June, 1856, from Chelsea to a point of the river beyond the influence of the tide, and the mortality of the Chelsea and Westminster districts, which are supplied exclusively by this Company, has diminished in comparison with that of the rest of London. The diminution is, however, not so great as in the districts supplied by the Southwark Water Company, for the Chelsea Company used to separate a great part of the impurity from the water by subsidence and filtration before its distribution.

I have not had an opportunity to inquire into all the diseases besides cholera, which have been diminished by the improvement of the water supply; but I find that, since the change in the source of supply of the Southwark and Vauxhall Company, there has been a marked diminution in the deaths from diarrhoea and typhus, in the districts they supply. Since the commencement of 1855 the weekly reports of the Registrar-General have contained the deaths from these two diseases in the different districts of London, and I have compiled, in table No. 3, the numbers of deaths from diarrhoea and cholera as they occurred respectively in that part of London situated in Surrey, and in the rest of London, from the beginning of 1855 to the end of 1857. It will be observed that in the two first quarters of 1855 the mortality both of diarrhoea and of typhus was higher in the metropolitan part of Surrey than in the rest of London; but that in the next quarter, that in which the supply of water was altered, the mortality of diarrhoea in this part of London fell below that of the rest of the town, and remained below it, with only two trifling exceptions to the end of 1857. The mortality of typhus in the Surrey part of London fell below that of the rest of the town, not in the quarter when the supply of water was improved, but in the following quarter, and has remained greatly below it ever since. I ought to remark, that the Registrar-General includes typhoid fever under the term of typhus.

I have in former papers adduced proofs that polluted water does not increase the prevalence of cholera by its acting in a general way, but only by conveying the special morbid poison of the disease, which must be present in the water, from a previous case or cases of the same malady. So, when polluted water increases the prevalence of other diseases, we must conclude from analogy that it acts in a similar manner, and that, when the water formerly supplied by the Southwark and Vauxhall Company increased the prevalence of diarrhoea and typhus, it acted by conveying the morbid material of these diseases from former patients.

The injury caused by impure water is by no means in proportion to the amount of impurity, but rather in proportion to the number of persons who respectively contribute to, and partake of that impurity. Thus a pump-well supplying a single family may be grossly polluted for years, without causing or communicating any illness, and if it do so at last, the illness may not spread beyond the family. Or a pump may supply a large population, but if polluted only by the cesspool of a single house, may be a long time before it does any harm; like the pump-well in Broad-street, Golden-square, which caused no mischief during three epidemics of cholera, but caused a great mortality in 1854. It is when a river receives the excretions of a town and at the same time supplies the population with water that the mortality is greatest, as shown in Hull during the cholera of 1849; at Newcastle and Gateshead during the cholera of 1853, and in certain extensive districts of London in every epidemic. And that increase of mortality which is so striking in time of cholera, goes on to a less extent at other times.

It follows from what I have said above that I should recommend the discontinuance of water-closets, or at least their diminution, instead of the continued increase of their numbers. A complete and well-regulated water-closet is so great a convenience that one cannot expect it to be discontinued in the better class of houses; but the so-called water-closet used by the working classes, who form the great bulk of the population, is according to the experience I have had, a worse nuisance than an open privy over a cesspool; as the recent excrement sticks about the pan and pipe, and is constantly disturbed by the water. In recommending the diminution of the number of water-closets, I of course do not suggest a return to the use of common cesspools; but some kind of moveable tank might be contrived, which should be charged with peat, or charcoal, or sawdust, or some other substance which would have the effect both of deodorizing the excrement, and bringing it into a state of disintegration, in which it could be more easily applied as manure. The tanks should be of a uniform size, so that a full one could be replaced by an empty one. It would be in new houses, and new neighbourhoods, that a plan of this kind could be best introduced. Dr. Hawkesley has contrived a plan for deodorizing the contents of water-closets, but he retains the use of the water.

As I have said above, the greatest evil of water-closets is the inordinate demand for water they occasion, and thus prevent most large towns being supplied otherwise than from the polluted rivers. If the general use of water-closets is to continue, and to increase, it will be desirable to have two supplies of water in large towns, one for the water-closets, and another, of soft, spring, or well water from a distance, to be used by meter, like the gas. Another evil of the general

adoption of water-closets is the waste of manure. The sewage becomes diluted with such an enormous quantity of water that it is doubtful whether it can ever be profitably applied to agriculture. The quantity of the sewage is so great that it could not be detained in reservoirs, and it could not be constantly applied, as the ground is often oversaturated with rain; whereas, if the solid excrement were conveyed away in carts, by some plan similar to the one I have mentioned, the house drainage, which would contain a good deal of the urine of the community, together with solution of soap and other fertilizing materials, would be so moderate in amount that it might probably be applied as liquid manure. It would most likely be five times more fertilizing than the present sewage. By the present plan, the proper contents of the house drains are vastly diluted with water, whilst the solid excrement chiefly lodges in the sewers, and has to be carted away from time to time, or is washed into the rivers by a heavy rain.

As regards water supply, it is desirable that all the shallow pump-wells, situated in towns and among houses, should be closed from domestic use, as they are extremely liable to be polluted, and that, as rivers can never be entirely free from pollution, the supply of towns should be from springs or wells at a distance.

In detached houses in the country, where well-water must be used, the wells should not be sunk close to the house, but at a distance; and the water should be conveyed to a cistern in the house by pumping it through a pipe, or in some other suitable manner.

As regards the great question of the purification of the Thames, I believe the part of the river which most concerns the public health is that in the neighbourhood of Thames Ditton and Hampton. I consider that the river in London was never in a better state, regarding it in a sanitary point of view. Not a single water company now obtains a supply from it, hardly any of the inhabitants on the banks dip a pail into it, and I believe the water is much less used among the sailors and others on board ship than formerly. I look on the question of diverting the sewage of London from the Thames rather as a question of taste than a sanitary question; and I shall not attempt to decide whether the improvement in the appearance of the river would be worth the cost. I only hope that, if the measure is carried out, the pump-wells along the course of the operations will be closed, to prevent such a prevalence of epidemic disease as occurred at Croydon; and that if the river is made to look comparatively clean the population will not again resort to drinking the water. If the sewage of London can be conveyed all, or part of, the way to the sea without polluting the river, it is evident that the sewage of Oxford, Windsor, Reading, and other inland towns, cannot be dealt with in a similar manner. The great sewage difficulty arose out of the almost general adoption of water-closets, and I believe it will continue until they are very much diminished in number.

18, Sackville-street.

#### EXPERIMENTS AND OBSERVATIONS ON THE ACTION AND SOUNDS OF THE HEART.

By GEORGE B. HALFORD, M.D.

Lecturer on Anatomy, Grosvenor-place School of Medicine, &c.

(Continued from p. 111.)

SINCE writing the former part of this essay, my attention has been kindly directed by Dr. Francis T. Bond, of Queen's College, Birmingham, to a paper in "The Monthly Retrospect of Medical Science," (Jan. 1849,) by Dr. Hamernik, recapitulating at some length the opinions of Dr. Baumgarten, "On the Mechanism by which the Valves of the Heart are closed, and by which the Sounds of the Heart are produced."

As my endeavour is, if possible, to unravel the intricacies of this subject, and to lay it bare before the Profession, I gladly transfer to these pages Dr. Hamernik's own words. He says, "The auriculo-ventricular valves are closed by the counter-pressure of the ventricular blood, suddenly developed by the contraction of the auricles; that the cavities of the auricles and ventricles during the heart's diastole are dis-

tended by the continuous current from the veins; while at this period the valves are to be found floating in the blood in the form of a funnel: that the object of the auricular systole is to induce such an amount of tension in the contents of the ventricles, and of course in the blood surrounding the funnel-shaped arrangement of the valves, as to cause their rapid closure; and in this way only can regurgitation be prevented."

Now, I grant that Dr. Hamernik is perfectly correct when he states that "the auriculo-ventricular valves are closed by the counter-pressure of the ventricular blood suddenly developed by the contraction of the auricles;" but he is incorrect when he says that "the cavities of the auricles and ventricles are distended during the heart's diastole;" for, as I have shown by the diagrams fig. 2 and 3, there cannot be full auricles and full ventricles at the same time within the pericardium, (*vide* also Table, showing the analysis of one complete action of the heart.) Nevertheless, the truth came out of Drs. Baumgarten and Hamernik's experiments, as witness the following remark of the editor of "The Monthly Retrospect:"—"The experiment by which it is shown that the auriculo-ventricular valve is closed before and independently of the ventricular systole is very easy of performance."

Dr. B.'s mode of demonstrating the action of these valves differs from that adopted by myself, in which, in imitation of nature, I effected their closure, and which I elsewhere explained as follows:—"The auricles contracting on the blood, the force of their contraction is transmitted by the blood in all directions, separating the flaps of the valves, distending the ventricles, and (the semilunar valves being shut down) pressing as much upwards and backwards as downwards and onwards. The force not being sufficient to raise the semilunar valves, is expended in distending the ventricles, and raising and closing the auriculo-ventricular valves."

Trusting, through the information by Dr. Bond, I have rendered proper acknowledgments to Drs. Baumgarten and Hamernik, I pass on to the consideration of the Sounds of the Heart.

The second sound of the heart is almost unanimously believed to be due to the tension of the semilunar valves of the aorta and pulmonary artery. The cause of the first sound, however, is differently stated by physiologists, inasmuch as up to the present time at least thirty explanations have been offered of its production. Need I say how detrimental to the study, and discouraging to the student of medicine have been this uncertainty and perplexity? The subject has by its occultness been peculiarly enticing to the speculative and fanciful; but it must not be left in such hands, it must be brought back and tested, both theoretically and experimentally.

Dr. Billing, in the preface to the second edition of his "First Principles of Medicine" (a work of which our Profession should feel proud), thus speaks of the sounds of the heart:—"In an essay read at the anniversary meeting of the Hunterian Society (February 9, 1832, and reported in the *Lancet* May 19, 1832), I first stated publicly that "the push or beat felt at the side is caused by the ventricular muscles, in their systole to expel the blood. The first sound is caused by the tension produced in the shutting of the auriculo-ventricular valves, and the second sound is caused by the tension produced in the shutting of the ventriculo-arterial valves," etc. etc. "This is a simple, unsophisticated explanation of the causes of the beat and sounds of the heart; and you will find that the morbid signs are all explicable as alterations of these." "Subsequently Rouanet brought forward the same explanation in his thesis, which was noticed in the *Journal Hebdomadaire* (September 1832), and copied into the *Médecino-Chirurgicale Review* (April 1833), as well as an extract from my essay; in which I had advanced, as I thought, sufficient to enable any practised physiologist to confirm my positions by the suggestions of his own mind. Finding, however, from some observations, that this did not appear to be the case, I published the following additional remarks in the *Lancet* (November 30, 1833):—"The succession of phenomena of the heart's action is as follows:—First, the auricle contracts, then the ventricle; by the action of which latter the auriculo-ventricular valves are shut by the pressure of the blood against them. Upon the relaxation of the ventricle, the semilunar valves are shut by the backward pressure of the blood in the artery. The first sound takes place exactly synchronous with the impulsion and action of the ventricle; hence it might be supposed that the action of

the muscle (as averred by some) produces the first sound. But the second sound takes place at a time when there is no action of the heart going forward; and this is peculiarly evident when there is an intermitting pulse, as there is then a marked pause after the second sound; so that, in fact, there is nothing but the semilunar valves in operation to produce sound at the instant." "I have thus proved that the second sound can be produced by nothing but the valves; and I have therefore shown the tension of the valves to be a sufficient cause for the first sound; and as *nil frustra natura facit*, according to the laws of reasoning in physics, more causes than are true or sufficient are not to be assigned (Newt. Princip. lib. iii. reg. phil. 1), so I discard muscular action as the cause of the first sound."

Speaking of the conclusions arrived at by the Committee of the British Association, appointed to inquire into the cause of the first sound, he further says:—"Now, as to their experimentum crucis (to show that muscle produced the first sound), of putting the finger into the heart after the valves were destroyed, and their hearing a sound proceeding from the contraction of the heart, with air, carnae columnae, and bloody moisture in it, without the fingers; doubtless there was a sound produced independent of the valves, but not the sound of the heart. I say my proof is legitimate—their assertion a sophism of *non causa pro causa*. It is the tympanic sound of the membranous valves which, with the time of the beats, produces the rhythm; and we judge of the existence of certain states of disease by the degree and manner in which they are out of tune. Looking at the subject physiologically and pathologically, valvular sound is the one we have to depend upon; for granting, for argument's sake even, that any other exists as a normal accompaniment, it has no more to do with the sound, than the drone of a bagpipe has to do with the tune."

Ignorant of Dr. Billing's priority, Mr. Bryan thus wrote, (*Lancet*, January 1833):—"I shall content myself with offering an explanation of the first sound, founded on a simple law of physics, examples of which are so frequently before us as to have rendered it familiar to every one."

"Any flexible solid, suddenly brought from a state of relaxation to a state of tension, vibrates, and its vibrations are sonorous or not, *i.e.* audible or not, according to its physical structure."

"At the commencement of the systole of the ventricles, their auricular valves are flapped into play, and at the instant of their closure, the whole substance of the ventricles and the valves are suddenly brought to a state of tension, and then consequently vibrate. I leave it to the reader to determine according to the laws of physics whether the vibrations of the valve, floating freely in fluid, or the muscular substance of the ventricles, trammelled by the contact of surrounding solids, would most contribute to the formation of the first sound."

Notwithstanding the above ably written theories, the valvular origin of the first sound had very few supporters. We now come to the experimental part of the inquiry.

In order to prove that *tension* of the auriculo-ventricular valves is sufficient to produce the first sound of the heart, Mr. Brakyn of Dublin devised an ingenious experiment, the details of which I extract from the *Lancet*, November 24, 1849:—

"The apparatus used consists of an ox's heart carefully dissected from the animal, so as to avoid injury to any of the appendages. To this I attached an apparatus consisting of a flanged tube, attached to the middle of the left ventricle, and piercing its wall, introduced through the auriculo-ventricular opening, to which was screwed externally another tube, with a flange also, so as to grasp the wall of the ventricle all round the tube, and render the junction air-tight; to the outer tube a bladder is tied. A free communication is thus established between the bladder externally and the cavity of the ventricle within. To the left auricle, a similar apparatus, but without flanges, was then attached by one trunk of the pulmonary veins, the rest being tied. Then having tied all the offsets of the aorta, I tied a tube and bladder to its abdominal extremity; to the distal end of this a small stopcock was then tied, into which a brass pipe, fastened to the end of an india-rubber one, can be wedged; the other extremity of the caoutchouc pipe is finally attached to the distal extremity of the auricular bladder. There is thus completed an apparatus, permitting a mimic circulation through the left heart, (it being sufficient

for illustration,) which may be conducted with perfect ease in the following mode:—

"Let the system be inflated with air through the orifice of the elastic tube next the stop-cock (marked by an arrow in the diagram); when, having wedged back the stop-cock into the pipe and opened the cock, a rhythmical circulation may be carried on by alternating manual pressure applied to each of the three bladders in succession (without removing any of the three hands applied), thus representing the successive contractions of auricle, ventricle, and aorta, with the natural attempts at regurgitation, which close both sets of valves in succession. Hereby a complete imitation of the normal sounds may be produced on either a very magnified or diminished scale, according to the force used in propelling the air."

"These sounds, being produced without any muscular contraction, or rush of blood, &c., must evidently be valvular, which can be further demonstrated by removing part of the apparatus (the auricular) so as to show the mitral valves in action synchronously with the first sound; or by introducing a wire cage, prevent them closing on regurgitation, when no sound follows; above all, the first sound is as perfect as the second, the valvular origin of which is, I believe, undisputed. In fine, the illustration, though conducted with air, ought to be conclusive, inasmuch as a suddenly strained membrane, which gives a tympanic sound in air, will do the same in water also, as I have tried, but not so loudly."

I had the good fortune to witness and assist at this experiment, when a pupil of the Grosvenor-place School of Medicine. Mr. Brakyn, going abroad, left the apparatus with two of the pupils, Messrs. Waters and Lercombe, who, with myself, frequently repeated the experiment, which was quite conclusive as to the valvular origin of both sounds. There being still an objection in the minds of some to this experiment, and an almost total neglect of Billing's original theory, I determined, in 1851, to see what would be the effect of fluids upon the valves; whether the tension produced by their resistance to compressed fluid would produce sound—such sounds resembling the two sounds of the heart.

It is evident that, to determine so delicate a point as the cause of the first sound of the heart, there must not be (as in the experiments of Hope, Williams, and the Committee of the British Association) any rude interference with the mechanism of the heart's action; its cavities must remain untouched; there must be no thrusting fingers into auricle or ventricle (as in theirs); no hooking back of valves (as in theirs); in fact, not one source of sound substituted for another, nor two or more brought together to discover one. My proceedings were as follow.

Large dogs were obtained, and, as in my preceding experiments, the heart was exposed, and the circulation kept up with artificial respiration. A stethoscope being applied to the organ, the sounds were distinctly heard. The superior and inferior venae cavae were now compressed with bull-dog forceps, and the pulmonary veins by the finger and thumb; the heart continuing its action, a stethoscope was again applied, and neither first nor second sound was heard. After a short space of time the veins were allowed to pour their contents into both sides of the heart, and both sounds were instantly reproduced. The veins being again compressed, all sound was extinguished, notwithstanding that the heart

contracted vigorously. Blood was again let in, and both sounds were restored.

I have thus frequently interrogated the same heart for upwards of an hour, and always with the like result.

This experiment (which was, at the time of my first performing it, in 1851, carefully examined, and verified by the late Dr. Marshall Hall and Messrs. Lane and Blenkins; more recently, and during the quiet of the night, by Messrs. Bickersteth, Waters, Fletcher, Grimsdale, M'Cheene, and Webster, of Liverpool; and lastly, for his own especial conviction, by Dr. Quain, of the Brompton Hospital) reduces the origin of the sounds either to the vibrations of the valves or to the rush of blood into and from the heart's cavities. That they need not be referable to the blood (that is, not generated in the fluid) is rendered certain by Brakyn's experiment, in which there was nothing but the *tension of the valves* to produce sound; and I will not admit that the flow of blood either into or out of the heart (in health) can produce sound; for if such were the fact, sound should be developed during the filling of the auricles, and subsequent injection and distension of the ventricles, that is, during the whole pause, which is not the case. (a) But ascribing, as I do, with Billing, Rouanet, Bryan, Valentin, Baumgarten, and others, the sounds to valvular tension alone, it becomes easily explicable why the first sound should be more prolonged than the second; for although the tension of the auriculo-ventricular valves is instantaneous, the vibrations of their flaps and of the chordæ tendinæ, by reason of their unequal sizes and attachments, are continuous; whereas, from the similarity of size and attachment of the semilunar valves, the sound resulting from their tension is limited.

That the blood closes both sets of valves is beyond dispute; that the force of the ventricular contraction is imparted to the blood, and by it transmitted in all directions must also be admitted. The valves between the auricles and ventricles being, as we have before seen, already in position, their resistance to the ventricular contraction must necessarily be accompanied by extreme tension and vibration of their flaps and tendons, (*first sound*.) At the same time the semilunar valves give way, and the arterial trunks become greatly distended. Then, the ventricular systole ceasing, this distension of the vessels is overcome by the elasticity of their coats, which second power reacting upon the blood, again impels it, its backward progress, however, being effectually impeded by the semilunar valves, (*second sound*.) Whereas no sound is heard, when, as in the last experiment, the blood is prevented entering the heart; inasmuch as the valves cannot be acted upon, the flaps of the auriculo-ventricular valves lying side by side, and the semilunar being immovably closed by the pressure of the blood upon their upper surfaces.

I contend, therefore, that the fact of both sounds being destroyed and reproduced by the same means is the greatest proof, and the first that has ever been given, that they depend upon the same cause, which is simply the vibrations of the valves produced by the backward pressure of the blood, first against the auriculo-ventricular (*first sound*), and secondly against the ventriculo-arterial valves (*second sound*).

The numbering of the Illustrations at p. 110 should be corrected; that on the right hand being Fig. 2, the other Fig. 3.

To be continued.)

**NORTH LONDON MEDICAL SOCIETY.**—The Annual Meeting of this Society took place on Wednesday evening, Feb. 10, when the oration was delivered by Dr. J. Russell Reynolds. The following officers for the ensuing year were then elected. *President*.—John Erichsen, Esq.; *Vice-Presidents*.—Dr. Jenner, Dr. Hare, Dr. Hillier, John Hainworth, Esq.; *Treasurer*.—Wm. Adams, Esq.; *Hon. Secretary*.—Robert Charles Croft, Esq.; *Councillors*.—Dr. J. R. Reynolds; Wm. Catlin, Esq.; Dr. Greenhalgh; C. J. F. Lord, Esq.; P. Mageniss, Esq.; Ed. Cousins, Esq.; Dr. M. Davis; Carr Jackson, Esq.; R. S. Myers, Esq.; Robert Burford, Esq.

(a) That the blood conducts sound, witness the heart's sounds heard on the pillow by night, when the circulation is excited, and the sounds sharper. How well, again, they are heard from the tiny fetal valves through both blood and liquor amnii!

## CASE OF

## EXTRACTION OF A FRAGMENT OF GUTTA-PERCHA BOUGIE

OF FULL SIZE, AND  $4\frac{1}{2}$  INCHES IN LENGTH, FROM THE URINARY BLADDER, BY MEANS OF THE LITHOTRITE.

By HOLMES COOTE, F.R.C.S.

Assistant-Surgeon to St. Bartholomew's Hospital, and to the Royal Orthopaedic Hospital; late Surgeon to the British Hospitals at Smyrna and Benkioi, etc. etc.

THE following case appears to me to present some points worthy of attention:—

Mr. P., about thirty years of age, was passing for himself a full-sized gutta-percha bougie, October 9, 1857, when the instrument broke between four and five inches from the distal extremity, and he found, upon withdrawal, that a fragment of that length was left in the urethra. He immediately called in a Surgeon, who endeavoured, by cutting into the urethra from the perineum, to seize the bougie, but while operating he perceived, and the patient himself felt a sort of spasmodic action of the urethra, and the whole fragment was drawn into the bladder. The patient came to town a fortnight after the accident, and called on me in good health, but in considerable agitation and distress. He said that hitherto he had experienced but little inconvenience, although there was an uneasy and sometimes painful sensation after the evacuation of the bladder, and occasionally a painful feeling referred to the glans penis. The urine was clear, and he could retain it the usual time. I sounded this gentleman, and immediately felt the piece of bougie, which appeared to lie transversely across the neck of the bladder. A blow with the steel sound communicated a dull sensation to the hand, from which I inferred that there was no considerable calculous deposit. The patient's urethra was very capacious, and he had never suffered from stricture.

It was obvious that the fragment of bougie must be removed, as its presence in the bladder would inevitably lead to results so well known that it is unnecessary for me to enter upon them here. The question in my mind was, what kind of operation was most likely to afford relief without endangering life. He himself, having read some medical works since his accident, suggested an opening by an incision along the median line of the perineum into the prostate gland and neck of the bladder, commencing behind the scrotum (a proceeding sometimes called Allerton's operation). Some of my colleagues thought that the lateral operation would be the readiest and the surest method. But, bearing in mind the numerous accidents and the high rate of mortality attendant upon the usual operation for extraction of the stone (lithotomy), I determined to act upon the piece of bougie with the lithotrite. The plan which I proposed and followed out was as follows:—

1. To introduce the lithotrite and seize the fragment very gently.
2. By a sliding movement to try to reach one of the ends; and by a turn of the screw to grasp it firmly, and pull the piece lengthwise through the urethra.
3. Failing in this attempt, to cut the bougie into fragments, and to trust to the efforts of the bladder for their expulsion.

My only fear (and that an unnecessary one) was that the blades of the lithotrite might become clogged with the gummy substance, and cease to move freely. But I was prepared, in the event of any accident which might prevent my withdrawing the lithotrite, to cut immediately into the bladder in the usual way.

October 26.—The bladder having been injected with about a pint and a-half of warm water, I introduced the lithotrite and seized the bougie. The instrument was made to slide along towards one extremity, when the blades were fixed, and the first attempt to withdraw the bougie lengthwise was commenced. Twice the bougie slipped from the blades of the lithotrite, and upon the third occasion blood began to flow in small quantity from the urethra. I felt that much damage might be done to the mucous membrane of the urethra by the forcible withdrawal of the bougie, bent and ragged, even were such an event feasible; and, inasmuch as I failed, I resolved upon crushing the bougie at once into smaller pieces. Accordingly the lithotrite divided it twice, and brought away some small bits of gutta-percha impacted in the blades.

No unpleasant symptoms having ensued, I repeated the operation on the Thursday following, four days afterwards. The bougie was not so easily felt, but it was again seized, and divided twice; larger fragments were withdrawn between the blades of the instrument, which were not tightly closed. But the bulk of the foreign body remained in the bladder.

About five hours afterwards I was sent for, the patient having experienced great irritation about the neck of the bladder. It was clear that a bit of bougie had entered the vesical orifice of the urethra. There was spasm, desire to make water, and to empty the rectum. An enema, containing 40 minims of laudanum, was immediately given, with orders to have it repeated, if necessary. During the course of the night severer symptoms came on, the patient walked restlessly about the room, and about three in the morning expelled, with a violent rush of urine in two acts, rapidly succeeding one another, the whole piece of bougie, about half with each of the expulsive efforts.

No symptom has since occurred, and the patient has returned to the country in good health.

I doubt not there are many Surgeons who have met with somewhat similar cases; but I have been induced to record the particulars of the present one, in consequence of the great diversity of opinion expressed by those among my friends with whom I spoke or sought advice. A very general feeling prevailed that lithotomy was the proper measure; and even up to the last the issue of the case, as treated by the lithotrite, was considered doubtful. I have not met with any instance in which a similar account of so large an instrument has been removed in the way here mentioned; although there are cases scattered through the public journals, in which pieces of smaller bougies have been successfully extracted. In the *Medical Times and Gazette*, Sept. 13, 1856, we see related the particulars of a case from St. Mary's Hospital, under the care of Mr. Lane, wherein a piece of gutta-percha bougie of small size broke off in the urethra of a patient suffering from stricture, and passed into the bladder. The ordinary assistance to be obtained from instruments such as a grooved sound was not possible; consequently, Mr. Lane proceeded to cut into the neck of the bladder in the mesial line, and extracted the fragment by a small pair of lithotomy forceps. The whole length amounted to about five inches.

Mr. Cock performed the lateral operation of lithotomy with success on a patient in whose bladder a piece of gutta-percha bougie, of the diameter of No. 4, and about five inches in length, had passed, in consequence of its breaking in the urethra. Here, too, there was a stricture rendering highly improbable any expulsion of the fragments by the natural passage.

A case, in some respects resembling that now before the Society, is related in the same journal by Mr. Hutchinson, of the Metropolitan Free Hospital. A piece of gutta-percha bougie, of the diameter No. 7, and about three inches in length, broke off in the urethra of a patient in whom no disease of the urinary organs existed, and passed into the bladder, as in the preceding cases.

No. 8 catheter was introduced without trouble, showing that the patient had a capacious urethra; and acting upon this fact Mr. Hutchinson made several, though ineffectual, attempts at extraction through this passage by forceps. He then distended the bladder with warm water, of which some was shortly afterwards voided. Six hours afterwards a strong desire to micturate came on, when the broken bougie was driven with force into the urethra, and was expelled without further difficulty.

I will not advert to the reprehensible practice of patients passing bougies for themselves, on account of some real or supposed disease of the urethra or bladder, further than by remarking, that in many of these cases the mind of the patient is in a morbid condition of anxiety or excitement. The first point to which I would draw attention is, that when the point of the instrument is fairly in the bladder, there being no stricture to interrupt its progress, its usual seat of fracture is about five inches from the extremity or tip, and that it corresponds to the part of the urethra anterior to the bulb, where the suspensory ligament binds the organ to the pubes, — in short, at the junction of the moveable with the fixed part of the urethra.

The muscular coat of the urethra draws the broken piece along the passage into the vesical cavity; when fairly lodged there, it lies somewhat transversely across the neck of the

bladder, the two ends impacted in the folds of mucous membrane; and there it remains, daily receiving its coating of phosphates.

The extraction of the foreign body is a measure which must not be delayed; and I think that this case is interesting, as showing how long a piece of a full-sized bougie may be expelled, when properly divided, through the natural passages, without the performance of any operation involving the prostate or neck of the bladder, a measure never unattended by danger. The fact, too, is of value in deterring Surgeons from forcibly drawing a large piece of bougie through the urethra, even should they be so fortunate as to seize it by one end, and so command its long axis; for the male urethra bears lesion of the mucous membrane very badly, and it is hardly possible to estimate the amount of injury which would be inflicted on the various ducts, both of primary and secondary importance, engaged in the formation of the spermatic secretion, or upon the walls of the canal itself, which might be subject to the formation of a stricture.

## THE LONDON PRACTICE OF MEDICINE AND SURGERY.

### GUY'S HOSPITAL.

#### LIGATURE OF THE EXTERNAL ILIAC ARTERY FOR A LARGE ANEURISM, UNDER POUPART'S LIGAMENT.

(Under the care of Mr. Cock.)

A man, aged 26, a baker, in delicate health, was admitted under Mr. Cock's care, towards the end of last November. Immediately beneath Poupart's ligament, on the right side, was a freely pulsating tumour, about the diagnosis of which there could be no error. Its projecting part was about the size of the rounder end of an egg, but its concealed portion appeared to be large. The man stated that he had first noticed it only a month ago. He had suffered extreme pain in the thigh and at the knee, along the course of the anterior crural nerve, which appeared to be pressed upon. He was very irritable and nervous. There was considerable deformity of the spine, and from a liability to attacks of sharp pain in the chest, with stethoscopic bruit over the heart, an aneurism of the aorta was suspected. It was evident that nothing could be done by the employment of pressure, and Mr. Cock accordingly decided without delay to put a ligature on the external iliac. This was done, without any unusual difficulty, on November 23, the part selected being about an inch and a half above Poupart's ligament. Pulsation ceased afterwards, and the pain complained of in the knee did not again recur. All went on as well as could be wished for some weeks. The ligature fell on December 8 (16th day), and at that time the wound was healed, excepting in the track of the thread, and the man's health had much improved. A minute fistula remained, but the man was so well that he was allowed to be up and about the ward until January 8. On January 8, a month after the ligature had come away, an attack of secondary hæmorrhage took place, and about a pint of arterial blood was judged to have been lost. The bleeding ceased spontaneously, and did not again recur. The man was afterwards, of course, kept quiet in the recumbent posture, but no local measures were called for. The sinus remained open, and continued to discharge a minute quantity of pus. During the night of January 24 sudden death, as if from cardiac syncope, took place. No return of bleeding preceded death, nor were there any circumstances other than the state of the thoracic organs to explain its occurrence. The aneurism had somewhat diminished in size during the time that had elapsed since the ligature, but its contents had not solidified.

The autopsy was conducted by Mr. Bryant, and the parts concerned in the disease and operation were carefully dissected. The aneurism was found to be not of the femoral

itself, but of the trunk of the profunda immediately after its being given off. The sac was large, and projected backwards under the muscles, until it reached the bone; the surface of the latter had been roughened by its pressure. But little of coagulum was found in its interior, its contents being chiefly grumous blood. The ends of the iliac artery, where it had been cut through by the ligature, were still unsealed, and a probe passed readily up and down its interior. Between the ends and enveloping them was a small mass of soft coagulum of dark colour, with the surface of which the still open sinus communicated. The artery above the site of ligature contained coagula, below it was quite empty. There was very little evidence of reparative action, and the wonder was that repeated and profuse hæmorrhages had not taken place. On examining the heart its aortic semilunar valves were found almost wholly destroyed by past ulceration. The other organs of the body, excepting that they were pale and in some instances fatty, did not present any special disease.

The early age at which the disease occurred, the coincident affection of the heart, and the fact that the artery involved was one which very rarely suffers, all combined in this case to point to a severe lesion of constitutional power. That such was really the fact the progress after the operation abundantly confirms. The man evidently possessed very little indeed of the *vis medicatrix* necessary for the reparation of injuries. His blood did not coagulate, nor was plastic material effused in sufficient quantity or of suitable kind to glue up the ends of the divided vessel. In what the systemic debility which caused the want of success consisted it is impossible to say. Its cause may have been some latent syphilitic or scorbutic taint in the blood, but these are mere guesses. The case is just one of those in which, as we remarked a few weeks ago in commenting on a similar one, the treatment by pressure, had it been feasible, would have resulted in disappointment. As to the immediate cause of the fistulous track remaining open, there could be little doubt but that the coagulum around the end of the vessel had prevented healing at the bottom. This coagulum had probably been effused early in the case. Apart from these considerations the case is of great interest as an example of idiopathic aneurism of the profunda, a vessel so affected with most extreme rarity. (a)

## ST. THOMAS'S HOSPITAL.

### ALBUMINURIA—LATENT PLEURISY—SUPERVEN- TION OF PHTHISIS.

(Case under the care of Dr. PEACOCK.)

A girl is now under Dr. Peacock's care in St. Thomas's Hospital, whose illness has furnished the opportunity for instructive observation as to the dependence of other organic affections upon disease of the kidneys. Her case exemplifies, 1st, the existence of albuminuria, without any tendency to anasarca, or other symptoms likely to attract attention to the kidneys; 2nd, the occurrence, in connexion no doubt with that disease, of extensive pleural effusion; and 3rd, the rapid supervention of tuberculous deposit in the compressed lung.

Abigail J., aged 18, was admitted in the last week of January. She is a very pale-complexioned girl, the clear watery brightness of her eye at once exciting suspicion as to the kidneys. Dr. Peacock has diagnosed tubercular softening of the left apex, and also the existence of a small quantity of fluid in the lowest part of the pleural sac. These conditions are chiefly of interest in connexion with the history of the early part of her illness, and this, as furnished by the Medical man who attended her, is as follows:—About two months ago, when living as housemaid in a very comfortable situation, she first sought Medical advice, on account of a very copious eruption of erythema papulatum on both legs; at the same time she complained much of feeling feeble, and unable to go about. Some of the spots were not unlike purpura; and on inquiry it was found that for a week or two past her gums had been liable to bleed when touched. She had disliked potatoes, and stated that she often passed a week without eating fresh vegetables, living on bread and meat. A mixture

containing chlorate of potash was ordered, and she was directed to eat vegetables and fruit freely. In ten days the eruption had disappeared, and she was as well as usual. About a week later, however, the Surgeon was again called in, and found her confined to bed with what she termed "a bad cold." She made no complaint of pain in either side, but stated that there had been a good deal in her back. She had no cough, nor any shortness of breath. An examination of the chest having, however, been made, the Surgeon was not a little surprised to find that the left pleura was filled with fluid to the very apex, and the heart displaced to the right side. On being closely questioned, she now recollected that four days before she had felt some pricking pains in that side, but they had not been at all severe. And now came the question of treatment. A condition closely allied to scurvy having been present only a fortnight before, the exhibition of mercurials was not to be thought of. It was determined to treat the case by diuretics and counter-irritants only, and accordingly a mixture, containing the acetate, nitrate, and bitartrate of potash was prescribed, and the chest was freely painted with a strong solution of iodine. Purgatives and blisters were subsequently used. It being found impossible to excite diuresis, and the condition of the chest remaining as before, an examination of the urine was made a fortnight later. This led to the discovery of albuminuria as a new complication to the case. The urine was scanty, of smoky tint, and, on boiling, deposited albumen most copiously. Diuretics as well as mercurials were now contra-indicated. Diaphoretics, vapour baths, and purgatives were during the next month sedulously employed, and with some advantage. On several occasions the secretion of urine was wholly suppressed for 48 hours at a time, and the condition of prostration was such, that speedy death was expected. At length, however, she recovered sufficiently to allow of removal to the Hospital, her friends being very anxious to have her placed under Dr. Peacock's care.

It would thus appear that the absorption of the pleural effusion has been slowly progressive during six weeks, and is at length nearly complete. Simultaneously, however, with its removal, the deposit of tubercle in the upper part of the compressed lung has taken place. It seems likely that albuminuria and consequent retention of urinary constituents in the blood have been the starting point in the rôle of morbid phenomena. Although the girl has never at any time had œdema of the extremities, yet her friends state that her complexion has for a year past been of the pasty pallor which it now exhibits. The influence of albuminuria in predisposing to serous inflammations and to extravasations of blood is well known. Respecting the connexion of diseased kidneys with the deposit of tubercle, opinions are much less unanimous. Dr. Peacock has indeed himself contributed the best collection of facts towards its determination.

Dr. Peacock, in the paper (a) to which we have made reference, supports the opinion (in opposition to that of Dr. Bright, and in conformity with that of Dr. Christison), that the tubercular diathesis powerfully predisposes to granular disease of the kidney. Of 117 cases of diseased kidneys, in which the lungs were examined, he states that in 36 or 30·7 per cent. they were found affected with tubercle. Respecting the priority of the two, he adds that "there seems every reason to believe that tuberculous affections of the lungs are very rarely secondary to the granular disorganisation of the kidney." Dr. Christison has stated that he has never met with a single instance in which the phthisis appeared to be secondary. This it must be observed is undoubtedly its position in the case given above, since in the beginning of her illness the girl had not the slightest cough, or other indication of pulmonary mischief. With regard to the prognosis of cases thus complicated, Dr. Peacock writes:—"We see, therefore, that the supervention of the renal disease during the progress of pulmonary consumption, both by the great liability which it induces to inflammation of the parenchymatous viscera and serous sacs, and also by the direct effects of the elements of retained renal secretion, tends very materially to add to the severity, and hasten the progress of the pulmonary disease." If this be true of the cases in which the renal disease is the later one, it must, *a fortiori*, be true of those in which phthisis commences after the albuminuria has long existed, and the spasmia attending it has become fully developed.

(a) In the Monthly Journal of Medical Sciences, August 1846.

(a) Mr. Bryant exhibited the preparation from this at the meeting of the Pathological Society on Tuesday evening, and stated that he had made a careful search in authorities, and had been unable to find another instance of aneurism of the profunda. He therefore deemed the case unique.

## THE ROYAL INFIRMARY FOR CHILDREN.

## LARGE UMBILICAL FISTULA COMMUNICATING WITH THE COLON.—OPERATION AND PARTIAL CLOSURE.

(Under the care of Dr. WILLSHIRE and Mr. COOPER FORSTER.)

THE subject of the following case was a little boy aged 5. The fistula, which was situate at the umbilicus, and was large enough to admit two fingers, had existed three weeks, and was believed to have been caused by a tubercular (?) abscess connecting the colon and abdominal wall, and finally ulcerating externally. The child was in a miserable plight, the fæces escaping to the amount of several ounces daily, and very small quantities indeed passing by the anus. His health was very bad. The fæces had an offensive odour, and were of such character that but little doubt was felt as to the bowel involved being the transverse colon. A probe was readily admitted in one direction, but encountered an obstruction when attempted to be passed in the other. The track of communication was very short, and direct. It was determined to attempt closure of the opening by a plastic operation, and its edges having accordingly been pared and dissected up, Mr. Forster united them across by the quill suture. Three sutures were put in, and the parts were retained by them in very excellent apposition. On the second day after the operation a good motion passed per anus, and until the removal of the sutures no fæces whatever had escaped by the wound. It was then thought that union of the whole length had taken place, but subsequently this proved not to be so. At present there is a small fistula about admitting a probe, through which daily a very small escape of fluid takes place. With the exception of the few drops which thus flow away, all the fæces now pass their natural outlet. No symptoms of peritonitis, nor indeed any undue disturbance, resulted from the operation, and the child is now in greatly improved health.

## HOSPITAL NOTES.

## DIVISION OF THE TEAR PUNCTUM AND ITS CANAL.

FOR the performance of this little operation Mr. Solomon has laid aside the knife and director, and substituted a pair of Mannoir's scissors, that have narrow blades and sharp points. The advantages of this change are,—he finds great facility and rapidity of execution, a matter of moment in nervous patients; the slit is always perpendicular; it never re-unites, and the sides of the canal remain well everted. The greatest width of the blades of the scissors he makes use of, is one-sixth of an inch, their length from rivet to point half an inch. Having first explored the canal with a probe to ascertain if it is stricture, and what its direction may be relatively to the margin of the lid and the caruncle, the operator, bearing in mind the anatomical arrangement of the parts, enters the punctum, while the lid is on the stretch, with the point of the lower blade of the scissors, and then slightly depressing the handle, slides the blade along the canal as far as the caruncle, where he pushes the point through the conjunctiva, and cuts out. If the punctum is constricted a common pin is used as a dilator before the introduction of the scissors. In the preceding description the lower canal is supposed to be the one selected for the treatment, though this method is also applicable to the upper.

## EXCISION OF THE HEAD OF THE FEMUR.

Mr. Coote has at present under his care in St. Bartholomew's a case which promises to do very well after the resection of the head of the femur. The patient is a lad, aged 16, in poor health. The disease was of two years' duration, and the head of the bone was dislocated on to the edge of the great sacro-ischiatic notch. The distortion was great, and there was much suppuration from the open sinuses. The resection was performed in the usual manner, the bone being cut through just below the base of the great trochanter. The lad's health has since much improved, and the wound is already almost healed.

## EXCISION OF THE ELBOW-JOINT IN A CHILD.

A case under care in Guy's Hospital, in which Mr. Cooper Forster performed excision of the elbow-joint in July last, has afforded a good example of the value of that operation. There were those who at the time expressed a strong opinion that amputation ought to have been preferred. The patient was a little boy, of ten years old, very delicate and strumous. The disease was of four years' duration, and the whole elbow was greatly swollen, there being many large sinuses and much ulceration. His health was rapidly failing, and amputation would have been quite justifiable. The excision was a complete one; the H incision was adopted, and the extremities of the three bones freely sawn away. The bones were found carious, and wholly denuded of cartilage. The case did uninterruptedly well afterwards, the parts healed soundly, the lad regained his health, and enjoys good motion in the false joint which has resulted.

## SPONTANEOUS ABSORPTION OF CONGENITAL DOUBLE CATARACT.

A case of congenital double cataract is now in attendance at the Birmingham Eye Infirmary, wherein vision has been restored in both eyes by the rapid absorption of the lenses, without the agency of an operation, or the occurrence of any accident that could rupture the capsules. The patient, an infant at the breast, when placed under the care of Mr. Solomon a month ago (January 9) was quite blind. The only treatment employed since its birth has been atropine drops to the eyes, and the administration once every day of a powder composed as follows:— $\beta$  Hyd. c. cretâ, pulv. Doveri, sacchari albi, aa. gr. j; ft. pulvis. On some future occasion full details of this interesting case will be published. The present very brief notice of it is now inserted in the hope that any one who has met with a parallel instance may be induced to communicate it to the Profession.

## CASES OF DIVERGENT STRABISMUS.

Several cases of divergent strabismus have recently been operated on at Moorfields. They are of interest on account both of their great comparative rarity and of the usually unsatisfactory result obtained. Mr. Critchett and Mr. Bowman, as our readers may be aware, are accustomed to insist most strongly on the vast superiority of subconjunctival myotomy over all other methods of operating for the convergent form. Mr. Bowman adopted it also the other day in two cases of external squint, but remarked at the same time that he did not deem the avoiding to cut the conjunctiva of such great importance in these as in the more common class of cases. There was no fear of the resulting depression in the outer side of the globe, which so frequently follows the old and clumsy procedure on the inner side, nor was there much fear of inversion. In one of the cases, however, a very slight inversion existed for the first week or two after the operation, and the non-division of the restraining mucous membrane was therefore a matter for congratulation. Mr. Bowman stated that he did not recollect to have ever observed a permanent convergent squint result from an operation for an external one; and Mr. Critchett added that his experience was similar. It must always be borne in mind in doing the subconjunctival division of the external rectus, that its tendon is inserted nearly a quarter of an inch further back than that of the inner muscle.

## THE PROVINCIAL PRACTICE OF MEDICINE AND SURGERY.

## THE YORK COUNTY HOSPITAL.

## ENCHONDROMA OF THE TESTICLE—EXCISION.

(Under the care of Mr. RICHARD HEY.)

ENCHONDROMOUS growths are among the forms of tumour to which the testis is most rarely liable. Their hardness and crispness on section led the older observers to mistake them for true scirrhus, and several specimens existed in our different museums so labelled until very lately. Into this mistake Sir Astley Cooper fell in respect to the specimen illustrated by Plate x. Fig. 2. The microscope affords an easy means of diagnosis, though, indeed, there ought never to

be much need for it in this instance. True scirrhus of the testis has, we believe, never as yet been observed. Of the enchondromatous disease a very well-marked example is recorded by Mr. Jabez Hogg, in vol. iv. of the *Pathological Society's Transactions*, page 181, and the description is illustrated by a good drawing from the microscope. The disease is usually associated with the development of cysts. It is often of rather rapid growth, but very rarely, indeed, manifests any of the characters of malignancy.

William Smith, aged 55, was admitted about three weeks ago, under the care of Mr. Hey, on account of great enlargement of the right testicle. According to his account, three years ago the gland had wasted to the size of a hazel-nut. It remained very small for about a year, and then began to enlarge. It had been throughout the seat of slight darting pain. Its enlargement was rather rapid, and in the course of two years it had equalled the size of two fists. It was very heavy and solid feeling, being also slightly nodular in parts. The cord was not thickened. Mr. Hey removed it in the usual manner, and the man is now nearly well.

The organ removed was a most excellent specimen of enchondromatous and cystic disease. Its section displayed numerous detached and nodular masses of white, glistening cartilage, from the size of a pin's head to that of half a walnut. In none had ossification commenced; indeed, that they yet retained the structure of foetal cartilage, and were of recent growth, was proved by the circumstance that, on maceration, the nodules became of a carmine tint, as does the cartilage of foetal bones and of exostoses in young people. The cysts were numerous, but none of them very large. The connecting tissue was a firm fibrous stroma, in most parts of a pinkish colour. Nothing that could be clearly recognised as gland-structure was seen, and it was impossible to state in what particular part the morbid changes had commenced.

## Medical Times & Gazette.

SATURDAY, FEBRUARY 20.

### THE MEDICAL DEPARTMENT AND THE SANITARY CONDITION OF THE ARMY.

THE articles which have appeared in the daily papers upon the sanitary condition of the army, as exposed in the recent report of the Royal Commissioners, show beyond all dispute the truth of the conclusion at which the Commissioners have arrived, that a large proportion of the mortality among British soldiers arises from causes which should not have been allowed to continue in operation,—in other words, that there is much unnecessary and preventable sickness and mortality in the army. It will be seen, by a reference to our Parliamentary Intelligence of the week, that the accuracy of the report as to the mortality of the Guards has been called in question. But on this point Mr. Sidney Herbert well observed:—

"Now, one thing is clear with regard to statistics—if you take single years or single periods, you are almost certain to be misled, because those years or periods may be exceptional; and therefore the only way to arrive at accurate results is to extend your examination over lengthened periods. The Commissioners took fifteen years, and the reason we stopped at 1853 was, that the war with Russia then broke out; and to argue about the mortality of our troops at home during the time they were engaged in operations in the Crimea, which

were most destructive to human life, would have been manifestly absurd. I believe the gallant officer opposite founded his belief that the Guards can now show better rates of mortality than those mentioned in our Report, upon the fact that during the last twenty months there has been a great decrease in the number of deaths. I am not surprised at that. The old brigade was almost destroyed in the Crimea; a new brigade has taken its place; that brigade is composed of young men, and a young life is better than an old one. Moreover, when the Guards came home they underwent a considerable reduction, and the men who were discharged were the weak and sickly; that left the brigade as young, as healthy, and as strong as it is possible to conceive an equal number of men to be; and no wonder, in these circumstances, that the rates of mortality show a decrease. But I contend that it would be wrong to place the mortality of the last twenty months before the public, and say, 'The Guards are in such a healthy condition, that there is no need for improving their barracks, or carrying out any of the recommendations of the Commissioners.'"

There is internal evidence in the Report itself of such extreme care in the statistical calculations, that we feel bound to assume their correctness, and admit the great unnecessary mortality in the army. But articles in the papers, and popular opinion, which is in a great measure founded on them, go further and lead very naturally to the conclusion that some one must be to blame. So far we are disposed most fully to agree with our political contemporaries and with the popular voice. But the reasoning is carried a step further. It is said, "The Medical Department of the Army is entrusted with the health and life of the soldier. His life is lost, his health is undermined, by influences which might be removed or prevented. The medical officer knows this, therefore he is to blame; the army surgeons are inefficient, the department has broken down, Dr. Andrew Smith is incorrigible. Down with the Doctors!" This really is, in a few words, the sort of reasoning into which the British public is falling. It becomes necessary, therefore, for us, as guardians of professional honour, to show that such reasoning is most unjust, and that it most certainly is not countenanced by the report of the Royal Commissioners.

Throughout the very able report of the Commissioners the feeling is apparent that it is their duty rather to point out evils and to suggest remedies than to expose defaulters. But they have taken especial care to show that the Medical officers are not the culpable parties—that the blame of unhealthy encampments, bad barracks, monotonous food, unsuitable clothing, and other causes injuriously affecting the health of the troops, should not be laid on the Medical Department.

With regard to the selection of encampments the Commissioners show that there is "no standing order or regulation making it imperative on the commanding officer in the field to consult the Medical officer;" that the commanding officer very likely "does not ask for the opinion of the Medical officer, and considers it intrusive if offered." Many instances may be found in the evidence in which Medical officers have been snubbed for making suggestions. In Sir John Hall's evidence it appears that some of the encampments in Bulgaria were selected not only without consulting him, but in absolute disregard to his written remonstrance.

Then as to the ventilation and cleanliness of barracks and quarters, the Commissioners tell us that the Medical officer has no power "to carry into operation any of the measures he may deem necessary, nor is there any regulation authorising him to press upon his commanding officer the adoption, or even the consideration, of his suggestions." The evidence affords abundant proof of this statement, and shows that the Medical officers are not consulted as to either the sites or plans of barracks, that suggestions for improvements are not attended to, and we might add, from our own knowledge of what has lately taken place at Melbourne, that both barracks

and hospitals are erected not only without the knowledge, but in direct opposition to the advice of the principal Medical officers of the station.

As to the sanitary condition of Military Hospitals, it is shown that the Medical officers have not usually been consulted as to the *sites* or *construction*—that the space and ventilation is generally inadequate—that the number of patients for an Hospital is decided by the barrack department, not by the Medical officers—that engineer officers refuse to make alterations or repairs suggested by Medical officers—and that recommendations of Medical officers on sanitary points of Hospital regulation are frequently disregarded. To take one glaring instance:—The great deficiencies in the Chatham Hospitals, the chief Hospitals of the British Army, which have been recently commented on, were pointed out by Dr. Andrew Smith so long ago as 1843, yet the Commissioners add that “the worst and most dangerous nuisances then complained of have not been removed to this day.” On this point Dr. Smith’s memorandum and papers submitted to Lord Panmure, which will be found in the Appendix, are worth perusal. Well may the Commissioners add:—“It is but just to the Medical officers to state that the evils complained of in the particular Hospitals we have described have been the subject of *constant though fruitless representations* on their part.”

The same old story might be gone through as to rations and clothing—the Medical officers are not consulted, and if they interfere their representations are disregarded.

It is very clear, then, that the Commissioners must not be represented as blaming the Medical department for the unnecessary mortality in the British army. The feeling they show throughout the report is quite the reverse. They appreciate very fully the difficulties under which the Medical Department labours from a total want of power, and the natural inference we have frequently insisted on before, namely—that the Medical Department must be invested with full and independent authority to carry out sanitary measures—that commanding officers should be compelled by regulation to consult the Medical officers on every sanitary question, and should be held responsible if they do not adopt the recommendations of their Medical officers on such subjects. The Royal Commission will confer immense benefit on their country should this most necessary reform be a result of their labours.

But we must not conclude without telling an unpalatable truth—the British public is to blame in this matter. It is easy to blame the Government, and we do not say they are blameless; but a system of rigid and wasteful economy is forced upon them by the public. Members are returned to Parliament pledged to retrenchment and economy, and the Army and Navy Estimates are most jealously watched by those who make political capital on a vote for the reduction of an estimate. This leads to extreme reluctance at the various departments to incur any expense not absolutely forced upon Government. Soldiers are crowded in small barracks. To give them more breathing space, larger barracks must be built at an increased expenditure for construction and repairs, and it has been the fear of this increased expense which has led Government to resist the demands of the Army Medical Department so long. We believe the report of the Commissioners will show that Government has misjudged the feelings of the people. Those who fight our battles must be well cared for at any cost, and this is pre-eminently one of those cases in which liberality is the truest economy. Let our soldiers be well housed, well clothed, well fed—give the Medical officers full power in all sanitary matters—raise their position in the army—and the next ten years will show a very different state of mortality in the service to the past.

## THE WEEK.

THE tribunal of the Seine has recently had before it an interesting case in the shape of an action brought by a nurse against the mother of an infant she had been engaged to suckle. It was proved that on her assuming this duty she was quite well, and her moral character is unsuspected. The infant, four months old, had an eruption on the face, which, however, the family doctor pronounced of an innocent nature. In about a fortnight she began to perceive an eruption about the nipples, and although the same Medical man pronounced this harmless, it continued to become aggravated, so that other practitioners pronouncing it syphilitic, she gave up the infant, which afterwards died of undoubted syphilis. The infant’s mother was a lady of good position and quite well, but the child’s father had died soon after its birth. The nurse brought the action for the damage her health had sustained, and the expense she had been put to for its reparation; and the tribunal awarded her 8000 francs damages, and all the expenses.

We have received, in a separate form, the copy of a speech delivered by Dr. James Burnes, K.H. F.R.S., at the Court of Proprietors of India Stock on the 27th ult. In this able address, the intended transfer of the power and patronage hitherto vested in the East India Company, into the hands of the dominant political party of the day is most strongly denounced. The misfortunes in India, both those which have lately occurred and those of an earlier date, are attributed by the speaker, not to the Company, but to the Government; and if the powers of the former should be abolished, it is predicted that a flood of corruption will overspread our Indian territories. The good government of India is said to depend upon the excellent local administration of its affairs; the authorities there being promoted for their good conduct and efficiency, and being untrammelled by political parties in the mother country. These arguments will no doubt have their due weight with the nation; and as far as the Medical appointments of the Company are concerned, we believe we are only expressing a very general opinion, when we allude to the present efficiency and good treatment of that part of the service, and to the anxiety evinced by the Medical staff lest a sweeping alteration should be made in the existing system.

We are very glad to find that there is a movement going on which will probably tend to alter and improve the method of conducting Medical education in England. A communication involving propositions to this effect has been made by one to the other of our great Colleges of Physicians and Surgeons. And both of them cordially agree to the principles suggested in it. The College of Surgeons has arrived at the conclusion that the direction in which it has been striving to extend, of late years, the education of the student is unfortunate; that the increased number of courses of lectures which its programme has compelled him to attend has not tended to advance him in a really useful knowledge of his Profession, but that, on the contrary, it has caused him to throw himself more than ever into the hands of the grinder. To remedy this evil the College proposes that the courses of lectures at present required from candidates by their Board shall be considerably reduced in number, so that the student may have some little time given him for digesting what he hears, and more opportunity and leisure for making himself more thoroughly acquainted with clinical surgery and practical anatomy. Every one conversant with the baneful effects of the present system of lecturing will be

delighted to hear that such a move is a-going on. How can it be expected from any living brain that it should take in anything but a mere smattering of what it hears, when its owner is forced hour after hour to be changing continually the course of his thoughts, and without a moment's interval to be rushing from one subject to another? We are also greatly pleased to find that the College considers a modification in the present prize system to be necessary, and that in all these particulars the two Colleges go cordially hand in hand. We sincerely congratulate them on this grand step forward. It is another lift of the mind out of the tangles which mediæval times have twisted around its movements.

We are happy to be able to announce that the Naval Medical Supplemental Fund is returning to a prosperous condition. The Society has been unpopular hitherto, in consequence of its unfortunate management in its earlier stages. But now that the crisis is past, it will no doubt be again sought after, and its advantages insured by its married members. A central committee and several local committees are now sitting and revising the standing regulations, as established by order in council. The Directors are now restricted to investing their capital in Government securities; and for this they only receive 3 per cent., the capital being nearly £66,000. It appears that the Directors of the Patriotic Fund are receiving 5 and 6 per cent. on their capital, on approved security. It is, therefore, proposed to ask for authority to invest to better advantage in Government or other approved securities. The receipts are now about £1980 per annum, exclusive of premiums and contributions, and if an addition of 2 per cent. to the dividends on capital could be gained the managers would soon be able to increase the widows' annuity very considerably. The widows in 1850 amounted to 225; they are now about 200; and from the advanced ages of many of them, this number must continue to diminish for some time. The managers of the fund deserve great credit for their successful exertions.

The case of the Queen v. Armstrong, just tried before Lord Campbell, is a forcible illustration of the importance of the movement recently set on foot for the establishment of Hospitals for the treatment of Dipsomania—or that desire to drink to excess which amounts to insanity. It is a matter of extreme difficulty to deal with these Dipsomaniacs—these maniacal or lunatic drunkards. It is easy to place them in a lunatic asylum; but directly the supply of stimulants is withheld, they speedily become sane; they cannot be detained longer, and as soon as they recover their liberty they return to the habits of excess which again reduce them to the insane condition. Dr. Peddie of Edinburgh has shown very forcibly the “desirableness of increased legal power to deal with drunken lunatics and maniacs,” though we do not quite agree with the plan he proposes of limiting the treatment of these cases to four asylums. The necessity, however, for some alteration in the law is clearly made out, for in this case of Mrs. Armstrong the jury were unable to agree upon a verdict, although Dr. Conolly deposed that she was “quite incapable of taking care of herself or her property.” The difficulty was, that if the passion for drink could be overcome, the evidence tended to show that the lunatic drunkard might become a sane woman. As is usual in medico-legal trials, the medical witnesses fell in for a very full share of abuse from the opposing counsel, but they can very well afford to despise attacks which would have been converted into a fulsome eulogium had the speakers been engaged on the other side.

## REVIEWS.

*On some of the more obscure Forms of Nervous Affections; their Pathology and Treatment. With an Introduction on the Physiology of Digestion and Assimilation, and the Generation and Distribution of Nerve-force, based upon original Microscopical Observations.* By HARRY WILLIAM LOBB, L.S.A. M.R.C.S.E. Pp. 312. London: 1858.

THE incongruous class of maladies known under the vague denomination of Nervous Affections has long offered insurmountable difficulties to the Medical practitioner, who has hitherto sought in vain for an explanation of their origin, and a rational set of principles for their treatment. That many of them are due to certain physical conditions of the assimilative and secretory functions, there can be little doubt; but, after eliminating all the cases which are distinctly connected with such conditions, a large number still remain, which appear to be dependent upon some molecular alterations in the nervous structures themselves, and are quite inscrutable by our ordinary methods of investigation. The researches into the pathology of the urine, by means of chemistry and the microscope, have opened a wide field of investigation, formerly very little explored, and have thrown great light upon the nature of many so-called nervous affections; while the theory of reflex action has enabled practitioners to give a rational explanation of, and in many instances to devise appropriate remedies for, a host of obscure morbid manifestations, which at no distant period were altogether inexplicable. Pathological anatomy, again, has investigated, with unwearying assiduity and some success, the morbid changes which occur in the nervous tissues themselves, and the subjective and objective symptoms to which they give rise; but truth compels us to admit that many of the derangements to which the nervous system is liable can be explained neither by the scalpel of the anatomist, the reactions of chemistry, nor the refinements of microscopical inquiry. The faculties of the human mind appear to become deficient whenever they attempt to lift the veil which conceals the mysterious nature of the union which exists between that mind itself and its corporeal habitation; nor are the mental powers much more successful when they endeavour to discover the exact agency by which nervous matter controls the physical changes which are occurring every moment in the living textures. The brain, the ganglia, and the nerves, may be likened to galvanic batteries and their conducting wires, and there is no doubt that the nervous influence and the electric fluid bear a very considerable analogy to one another; but analogy is not identity; and even admitting that electric and nervous influence may be more closely allied than they are now supposed to be, the question arises, How the battery of the nervous system is set in motion, how it is interrupted, and what are the results of its action?

Such being the difficulties (and we have mentioned only a very few of them) attendant upon investigations into the functions and the derangements of the nervous system, we cannot be surprised if Mr. Lobb has not entirely succeeded in a task which has puzzled the most distinguished physicians, physiologists, and metaphysicians of all ages. Much credit, however, is due to him for the laborious industry which he has brought to bear upon his subject, both by original observations and the perusal of the works of trustworthy authorities. His book is full of quotations from some of our best writers on Medicine and the allied sciences; and there are a number of illustrations of microscopical objects, many of which are original; although it does not strike us that these latter illustrate any points of great importance, or clear up any acknowledged obscurities.

The great defects in Mr. Lobb's work seem to be a habit of hasty generalization, and the practice of taking for granted views and opinions which are by no means established. These defects are palpable at the very outset of the book, for in the introduction, after a number of aphoristic remarks, to many of which no objections can be raised, but which are not new, comes the following passage, which we quote entire, the italics being our own:—

“The ultimate atoms of all matter are spheroids in a state of vibration. (?) To prove this, I shall take an atom of water as the example. Water is the result of the union of the two gases oxygen and hydrogen; the atom of water, therefore,

must contain two constituents in opposite stages of vibration, one more dense, the other less dense. (?) Each constituent while undergoing the expanding stage, must be negative, while the contracting, positive. (?) In relation to each other, the less dense must be negative, the more dense, positive; in relation to surrounding bodies the reverse. (?) A current must exist through the atom, passing in by the more dense, and out by the less dense. (?) So that a certain volume of oxygen gives off as much of the force while undergoing the contracting stage as double the volume of hydrogen can absorb during the expanding stage, or exactly as much as the latter has imparted to surrounding bodies during its previous contracting stage. Thus their vibratory powers must be as two to one relatively to their bulk, oxygen having double the vibratory power of hydrogen." (?) P. 6

We confess our inability to understand this passage, which is not in any way connected with anything which has preceded it; and without denying that the ultimate atoms of matter may be spheroids (which, indeed, is probably the case) we conceive that Mr. Lobb's reasoning does not by any means prove that view to be correct.

We could point out many passages in the book which show an equal amount of loose reasoning; but we refrain from any further remark, in the hope that, as Mr. Lobb's views become matured by reflection and experience, he will succeed in eliciting some important truths as the results of his undoubted care and diligence in the collection of materials for inquiry.

*Observations on the Human Crania contained in the Museum of the Army Medical Department, Fort Pitt, Chatham.* By GEORGE WILLIAMSON, M.D., Staff-Surgeon Second-class. Dublin: 1857.

THE Museum at Fort Pitt contains, among many other objects of natural history, a large collection of the skulls of human beings of all nations; and in the pamphlet before us Dr. Williamson has presented us with a *catalogue raisonné* of the crania, determining the anatomical characters exhibited by each. Besides other peculiarities distinguishing the skulls of the different members of the human race, Dr. Williamson attaches much importance to the shape of the anterior nasal aperture, the various configurations of which are supposed by him to denote in some degree the national character.

*Histoire des Bains de Dieppe; précédée d'une Esquisse de l'Histoire Générale du Bain.* Par P. J. FÉRET. Dieppe. *History of the Baths of Dieppe; preceded by a Sketch of the General History of Bathing.*

THIS book contains a history of bathing from the times of Adam and Eve to those of Louis Philippe and Louis Napoleon. It enters largely also into the history of the town of Dieppe, and of its accommodations for bathing. It is a good specimen of book-making; and, although it is of little value in a scientific point of view, it will perhaps afford amusement to persons who wish for some light reading while residing at Dieppe.

*A Compendium of Qualitative Analysis, from the Simplest to the most Complex Cases, arranged in a Series of Tables.* By F. W. GRIFFIN, Ph.D., Director of the Bristol School of Chemistry. Bristol: 1858.

THE six tables of Dr. Griffin are supplied bound in a volume, or mounted on stout boards and varnished for use in the Laboratory. After examining the tables we have formed a very favourable opinion of their accuracy and probable utility, and we find that practical chemists who have checked the numerous processes and statements set forth, thoroughly coincide in this opinion. The adoption of these tables would, we feel convinced, materially lessen the labours of both, teachers and students of practical Chemistry, and we can therefore, recommend them very warmly.

**THE ANATOMY ACT.**—The Medical Students of King's College have presented addresses to the four "Examining Boards," praying them to employ their influence to induce Government to consent to such alterations in the above Act as may insure to the London Schools a more regular, certain, and a cheaper supply of subjects, and render the repetition of such cases as that which led to the present almost complete stoppage impossible.

## GENERAL CORRESPONDENCE.

### MR. SYME'S CASE OF CANCER OF THE TONGUE.

[To the Editor of the Medical Times and Gazette.]

SIR,—There are occasions on which a man may be permitted to speak of himself without the imputation of egotism, and be exempted from the charge of presumption, in expressing through the public press those strong feelings of honest indignation, which cowardly attacks upon his character, conveyed by false and deceitful innuendos, naturally arouse. I am called upon to make this appeal in self-defence by the vulgar defamatory sneer of Mr. Syme, who, in his letter of the 26th ult., says that his "silence will not occasion any surprise to those who are acquainted with the [my] position of the author." I call upon Mr. Syme to explain the meaning of so base an insinuation. Let me tell Mr. Syme that throughout a life as long as his own, and in every relation of it—professional and public—in the latter infinitely more varied than his—that my word is respected by all who know me, and I am content, in an unambitious sphere, to have a name beyond reproach and suspicion, which I have never lowered by reducing myself to the "position" Mr. Syme has occupied since £250 damages were awarded against him by an Edinburgh Jury for a libel on his professional brother, Mr. Glover.

With regard to the intimation in my last letter, to show Mr. Syme's "position" in a late important surgical operation, I may shortly premise that the cultivation of all knowledge depends upon freedom of discussion and unrestricted communication, for truth fears nothing so much as concealment, and experience, from being the safest guide, ceases to be one, so soon as its results are ignored. In no department of human knowledge are "free-trade principles" more applicable than to pathological research. For unless the relation between morbid living action and its cause as unfolded by dissection, be accurately traced and faithfully recorded, Medicine, with its defective title to rank as a science, would be reduced to a mere chaotic collection of incoherently observations, little removed from empiricism. And in order to illustrate how much the cause of clinical teaching may be injured by the neglect of such a principle, I shall briefly submit to your readers, leaving them to form their own comments, the particulars of the case of the excised tongue, in which Mr. Syme operated, as furnished by public documents. My object will be obtained if this communication has the effect of introducing the system, which obtains in all the hospitals of London, of publishing full reports of every important post-mortem examination, etc., into practice in the Infirmary at Edinburgh.

To make the history of the case continuous from the commencement, and more intelligible, I shall prefix two of the notices which were taken of it in a daily newspaper here.

From the *Daily Scotman*, December 14, 1857:—

**"REMARKABLE OPERATION IN THE INFIRMARY.**—An operation was performed by Professor Syme, on Wednesday last, the 9th, which has occasioned great interest in the professional world and beyond it. A countryman, in the prime of life, and apparently in perfect health, came into Mr. Syme's Ward with a malignant disease of the tongue, causing constant and most severe pain, incurable by any general or local means, and certain to prove fatal. Mr. Syme explained to his students, before commencing the operation, the state of the case,—intense suffering and certain death, if left alone—relief from present pain, and a reasonable chance of ultimate recovery, if the entire organ were removed. *This, he stated, had never been done before, and he said he considered himself warranted in trying it.* The patient, a resolute man, who put his life frankly into the hands of his Surgeon, was put under chloroform; the jaw was divided, and free and safe access obtained to the seat of the tongue, which was rapidly and absolutely removed, leaving not a trace of the disease, or of the organ in which it was seated. The patient walked out of the theatre, speechless, but grateful and happy, and has continued well ever since, being fed with a tube. He can now, however, swallow, and yesterday he spoke, or rather breathed out the word, 'Milk.' He is cheerful, and gives every hope of thorough recovery. The operation was performed in the great operating theatre, before the largest number of spectators probably ever in it—Medical men of all ages, from the student

in his first year, to the grey veteran from the Peninsula or the Crimea. These 500 spectators are not likely soon to forget *that scene—as intense a bit of tragedy*, though in common life, as any old Greek would have desired, 'to purge the soul with terror and pity,' having the advantage over the classic Tragedy, that it *ended happily and for good*; and that, thanks to the blessed chloroform, its very doing was quiet and painless. A great Surgeon has many of the highest qualities of a great general, and some peculiar to himself. He has at once power and promptitude, knowledge of what is, and readiness for what may be—a combination of mental, moral, and physical virtues, as rare as they are inestimable."

From the *Daily Scotsman*, December 21, 1857:—

"**LATE OPERATION IN THE INFIRMARY.**—We understand that the patient who had his tongue removed went on very well for nearly a week, when the external wound was quite healed, and everything promised fairly for his recovery, but that he then rapidly sunk. On examination, it was found that the cause of death had no direct connexion with the operation, and was one which might have proceeded from any other source of irritation. It is proper this should be known, since the principle involved in the operation may be of consequence in the practice of surgery. It may be remarked that the patient was a man of intemperate habits and bad constitution."

From the *Times*, December 22, 1857:—

"**THE OPERATION FOR CANCER OF THE TONGUE.**

"To the Editor of the *Times*."

"SIR,—I regret that an operation which I happened to perform in the Royal Infirmary of this city has got into the newspapers; but as it has unfortunately done so, the PUBLIC should be correctly informed on the subject. Partial removal of the tongue for the remedy of cancer having been found worse than useless, it was thought that extirpation of the whole organ might afford effectual relief; upon this principle I proceeded.

"The patient suffered no bad consequences directly from the operation; but at the end of a week, when the external wound was quite healed, died suddenly from an internal disease, which might have been excited by any other irritation in a person of his constitution and habits.

"I am, Sir, &c.

JAMES SYME.

"2, Rutland-street, Edinburgh, Dec. 19."

The only other gleanings regarding the case are to be found in Mr. Syme's letter of the 9th January, 1858, published in the *Lancet*. In it he states, "Until the fifth day" (in his letter in the *Times* it was, he says, *at the end of a week*, but by that period the patient was dead, the operation, as reported in the *Scotsman*, having been performed on Wednesday the 9th December, and the man dying at one o'clock, p.m. of the succeeding Wednesday) "the patient was perfectly well, but then all at once his breathing became embarrassed, and his strength rapidly sank, so that he died in two days afterwards." Mr. Syme further states:—"On examination, every thing was found in the most satisfactory state, so far as the throat was concerned, and no appearance of disease could be discovered anywhere except in the lungs, in which the substance was thickly interspersed with incipient abscesses." In conclusion, "Mr. Syme suspects that mischief may have arisen from the well-meant, but not very judicious trials of the attendants, upon his powers of swallowing;" and makes the remarkable admission, "that the patient cannot be regarded as a favourable subject for the operation."

What says the certificate of the House-Surgeon in the Infirmary to all this?—How stands his certificate of the cause of the patient's death, with the object of Mr. Syme for publishing his letter in the *Times*, viz. "that the public should be correctly informed on the subject?"

Extract from the Register Book of Deaths, for the district of St. Giles in the City of Edinburgh:—"George Smith died in the Royal Infirmary, 1h. pm., 16th December, 1857. Cause of death, *Pyæmia*, in consequence of operation for cancer, as certified by Frederick Gourlay, M.D.

"DAVID BEATSON, Registrar."

Your readers may possibly inquire, if there was a consultation before the operation, who were present, and what was resolved on at it? what appearances the tongue presented after excision on microscopic inspection? where is the full report of the appearances found upon dissection, as drawn up by the Pathologist of the Infirmary, whose duty it is, and for which he is paid, to furnish the necessary and important document? Has information on these points been given to his Profes-

sional brethren at the last meeting of the Medico-Chirurgical Society, of which Mr. Syme is a member, or been published for the benefit of the general Profession, in either of the last two numbers for January and February of the *Edinburgh Medical Journal*, or afforded by a public lecture to the students? or is it possible that such a document should have been withheld altogether from public inspection? Were the incipient abscesses microscopically examined, and did the structure of their coats or their contents exhibit any indication of a cancerous character? Were there any suspicious morbid lesions found in the pterygoid muscle, or parts adjacent to the tongue? and was the external wound wholly, or only partially united? Mr. Syme can best answer all these interrogatories. I can only say that I have been informed that the students have been denied all access to the Pathologist's report, and I have not met a Professional acquaintance who has seen it.

I am, &c.

JOHN RENTON, M.D., etc.

5, Eastfield, Leith, Feb. 8, 1858.

## POOR-LAW MEDICAL REFORM ASSOCIATION.

[To the Editor of the *Medical Times and Gazette*.]

SIR,—The annexed letter from the Poor-law Board fully proves that there is no disposition on the part of that body to assist their Medical officers.

COPY.

"Poor-law Board, Whitehall,

"11th February, 1858.

"SIR,—I am directed by the Poor-law Board to acknowledge the receipt of your letter of the 20th ultimo, respecting the amount of remuneration assigned to you as the Medical officer of the Weymouth district of the Weymouth Union.

"The Board have considered the statements which you have submitted to them on this subject, but are of opinion that there are not sufficient grounds for their interference.

"I am, Sir, your obedient Servant.

"COURTNEY, Secretary."

"To Richard Griffin, Esq., Medical officer,  
12, Royal-terrace, Weymouth."

It may have escaped your recollection that during the last two years and a half I have repeatedly complained of the inadequacy of my salary compared with the duties to be performed, and also of the unfair treatment of the Guardians, who pay me but 1s. 3½d. per case, while they give to another officer 16s. 3d. per case, the patients being respectively equidistant from our residences.

The Statistical Society of London has lately published a report on the Dispensaries and Hospitals of the Metropolis, and from this document I find the expenses of the former average 2s. 5½d. for each patient, and those of the latter 12s. 6½d.; supposing 7s. be deducted from this last sum for board, etc., for the entire number of in- and out-patients. Though applicable to the former only, it will follow that the cost of the Medical treatment alone of Hospitals and Dispensaries united is not less than 4s. 6d. per case. How then is it probable that Poor-law Medical officers can do their duty to the poor and meet the expenses of surgery, horses, carriages, servants, etc., out of salaries that average but 2s. 9½d. per case; and still less is it possible for those men who have but 3d. per case. With a full knowledge of all these facts the Poor-law Board "are of opinion that there are not sufficient grounds for their interference" with the Weymouth Guardians, though I receive but an average payment of 1s. 3½d. per case, and for this sum perform capital operations. It is therefore perfectly clear that our only chance of redress is from Parliament, and even from that quarter we cannot hope for assistance until after the Easter recess, as so many other important topics engross attention. I have in the press a pamphlet which I trust will convince the Legislature of the necessity of passing a law to improve our position; it includes the draft Act of Parliament, which has been materially amended since last seen by the Profession, and it also contains twenty-eight pages of classified extracts from the official circulars of the Poor-law Board, which will be of great value to every Union Medical officer as a source of reference on doubtful points. The cost of getting up this work has been great, consequently the distribution will be confined to the members of both Houses of Parliament, and the subscribers to the Poor-law

**Medical Reform Association.** As only a limited number of copies will be printed, those gentlemen who desire to possess one must subscribe without delay, otherwise they may be too late—a reprint being quite out of the question. Of the 657 Unions, Incorporations, etc., some of the officers (and in many instances all,) from 510 have joined the Association; of 3317 Medical officers very many send their sympathy and good wishes, and say they will petition, but 1230 only have contributed to the funds, which will be exhausted by the time the pamphlet, containing about 100 pages, is distributed. I therefore hope that every Union Medical officer will see the imperative necessity of adding his mite to assist in supplying the means to carry on a struggle which is not only for the good of the Profession, but also for the benefit of the poor.

I am, &c. RICHARD GRIFFIN.

12, Royal-terrace, Weymouth, Feb. 13, 1858.

## ROYAL COLLEGE OF PHYSICIANS, EDINBURGH.

[To the Editor of the *Medical Times and Gazette.*]

SIR,—In the *Medical Times and Gazette* of the 13th inst. an advertisement from *Coleraine* is quoted, at the foot of which a Mr. James Barr is designated "Surgeon, and Licentiate of the Royal College of Physicians, Edinburgh."

Permit me to inform your readers that the class of "Licentiates" of this College has at present no independent existence, all its living representatives having long held the higher title of "Fellow" of the College; and that upon referring to the lists of Licentiates and Fellows I have not been able to find the name of James Barr.

I am, &c.

WILLIAM ROBERTSON, M.D. Hon. Sec.

Royal College of Physicians, Edinburgh,  
Feb. 16, 1858.

## REPORTS OF SOCIETIES.

### ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, Feb. 9, 1858.

Sir C. LOVCOCK, Bart., President, in the chair.

#### The SECRETARY read a paper by Mr. HUTCHINSON entitled SOME PARTICULARS OF A CASE OF MARKED BRONZING OF THE SKIN.

The woman whose malady formed the basis of this communication was exhibited to the Fellows, and was declared by Dr. Addison to be a good example of that peculiar condition, both of general health and discoloration of skin, which he has found so frequently connected with disease of the supra-renal capsules. Mr. Hutchinson's notes embraced the usual history of these cases. He gave his reasons for arriving at the confident opinion that this was a genuine example of diseased supra-renal capsules, as well as those which induced him to conclude that both organs had probably been destroyed as long as two years, and called attention to the two important points thus illustrated—viz. the length of time during which life may be prolonged in the human subject after destruction of those organs, and, consequently, the necessity for caution in the attempt to deduce conclusions from experiments on the lower animals.

Dr. ADDISON remarked, that in a matter somewhat novel, and so extremely imperfect, it was natural that any one, although deeply interested in it, must feel considerable reserve in speaking upon such slender testimony as at present existed. If not irregular, he would refer briefly to a case of this kind, brought before the Society a short time ago, as affording what he considered the most perfect and unequivocal, and at the same time the most terrible illustration of the disease to which the attention of the Society was directed. The case was that of a young lady, only eighteen when she died, who was amiable, intelligent, and accomplished, and till about two years before her death, during which period she had been observed to lose health, and strength, and colour, was ap-

parently sound and healthy. When he went to Ashford to see her, he was very much struck with her appearance; for a more terrible sight of disease he never beheld. She was darkened, almost blackened, as if stricken by some supernatural power; she was anæmiated, had a pulse like a thread, and so feeble was the circulation that she could not sit upright without becoming blind. He could not, therefore, entertain a doubt about the case, and did not hesitate to express his confidence respecting it. In no long time she died. At the post-mortem examination there were present besides himself three Medical gentlemen, who had been struck during life by their inability to detect a sign of disease in any organ. The body was not particularly emaciated; there was a fair supply of fat in the omentum and the region of the abdomen. All the abdominal viscera were found perfectly healthy. The only vestige of a disease was a small pediculated cyst, about the size of the kernel of an almond, attached to one of the broad ligaments, which he supposed could not have much to do with the malady. A healthier chest he never saw; there was not the slightest adhesion even between the pleura; the lungs collapsed, but were perfectly free from all deposit and trace of disease. The heart, as might be expected, was feeble and flabby; but there was no disease of the organ. They then proceeded to examine the supra-renal capsules. Those capsules were greatly enlarged, especially the left, and both of them were universally converted into a bag of pus, which escaped in considerable quantity. Now, suppose that the symptoms were not resulting from disease of the supra-renal capsules, but from a diseased condition connected with some other lesion not yet discovered, what were the chances of finding these organs diseased? The chances were almost incalculable; and they became much more strongly so when it was remembered that there was no other organ in a diseased condition. The conclusion, therefore, appeared to him inevitable, even if there were no other cases on record, that the discoloration in this case did result from disease of those organs, and probably from disease of those organs alone. We knew, however, that these organs were situated in the direct vicinity, and in contact with the solar plexus and the semilunar ganglia, and received from them a large supply of nerves; and who could tell what influence the contact of these diseased organs might have on these great nervous centres, and what share that secondary effect might have on the general health and in the production of the symptoms presented? He did not know whether there had been hitherto sufficient carefulness of examination to ascertain whether any positive lesion existed in the tissue of the nervous structure; certainly in the case to which he had referred it had not been ascertained. There were, indeed, many objections and difficulties raised upon the subject, and he had seen enough of modified cases to justify many of them. Suppose, for instance, these organs played an important part in the functions of the body, however slowly their lesion might affect the general health or destroy it, it was not impossible to suppose that they might be variously diseased, and in various degrees, and the effects correspond with these various degrees of morbid condition. He could very well understand that the organs might be even functionally diseased, and there might be more or less of the discoloration, and the other symptoms that had been described, without any organic lesion at all, as was the case with other organs of the body. Some time ago a man called upon him with the symptoms of the disease strongly marked; but by good support, sending him into the country, and giving him ammonia and other stimulants, he had shaken off a great deal of the want of tone and energy he formerly manifested, and considered himself, no doubt justly, very much better. He had also a woman in Guy's Hospital, who had a psoas abscess in addition. That woman had been very deeply discoloured, and her constitution appeared very powerfully affected by one or the other, or by both; but she had now more energy than she had some time ago, and her colour was certainly less. From what he had seen of the organic changes that take place he could understand why there should be an arrest, very probably a complete and permanent arrest of the disorder. We knew the depositions that took place into one or both of these organs—more probably into both at the same time—and indicating a special and peculiar tendency of the organs when affected; some would call these deposits scrofulous, some malignant; we knew also the natural course these depositions

underwent, softening and being converted into a puriform mass, they became quiescent, having been attended by inflammation during the process; and we could therefore very well imagine that while this limited deposit, not such as to interfere with the whole of the functional part of the organ, was undergoing a change, there would be a very considerable amount of inflammatory action and disturbed function around, which would produce great general distress and discoloration. But that on the softening process ceasing, and the part becoming quiescent, the function of the kidneys would be restored, and the health restored with it. This was, of course, reasoning from what we knew of the diseases of other organs. But there were other sources of disputation which were perhaps more avoidable, and perhaps less legitimate. He had cases sent to him of discoloration of the skin, which did not approach to anything like the discoloration attending this lesion. It had, again, been more than once declared that these organs were diseased, and extensively so, when there had been no disease at all. Several supra-renal capsules had been sent to him as samples of diseased organs, and they were in a state of perfect health. Such a case had been published to the world as a remarkable instance of universal disease of both organs, without any discoloration of the skin. It appeared to him that the amount of discoloration had, in the instances he had met with, been connected with the softening process or liquefaction of the contents of the organs; so that where there had been great intensity of discoloration, there had also been great liquefaction.

THE PRESIDENT inquired whether the case that had appeared in the room was a fair specimen of the discoloration.

DR. ADDISON replied that, as far as he could judge by candle-light, it appeared to be perfectly so.

DR. HARLEY said, the Profession was greatly indebted to Dr. Addison for having called attention to a peculiar, important, and hitherto unnoticed disease. He had listened with pleasure to the notes of the case, but could not help feeling somewhat surprised at the conclusions of the author. He did not think there was at present sufficient evidence to justify the dogmatic statement that bronzing of the skin was pathognomic of supra-renal capsular disease. No doubt many cases had been reported in home and foreign journals, in which a peculiar discoloration of the skin was found associated with disease in the supra-renal capsules; but that was not sufficient to establish the relation of cause and effect. Indeed, during the last year a considerable amount of evidence had been brought forward on the opposite side of the question,—cases having been reported in which extensive disease of the supra-renal capsules was unconnected with any discoloration. He referred to the cases reported by Ogle, Virchow, Davies, Fredrich, Brittan, Kolb, etc. On the other hand, several cases of bronzed skin had been noticed, unassociated with any textural change in the supra-renal bodies, as that brought before the Pathological Society last summer by Mr. Hutchinson. He did not believe bronzed skin to be the result of any particular disease attacking the glands; for Dr. Addison had just shown that the discoloration accompanied tubercle, cancer, and abscess of the capsules. It had been said that the bronzing of the skin was the result of the suppression of the supra-renal capsular function; but how could that be the case when the discoloration was found in cases where the capsules were perfectly healthy, and was absent where the glands were too extensively diseased to perform their function? In discussing a subject like the present, he considered it better to take a general view of the chromatogenous function of the skin than confine attention to individual cases; and he reviewed in some detail the several causes regulating the deposition of pigment in the skin of man and of the lower animals. Many physiological proofs were deduced to show that the chromatogenous function of the skin was entirely independent of the supra-renal capsular function.

MR. HUTCHINSON remarked, respecting the greater part of Dr. Harley's observations, that they were admitted by every one. No one had ever doubted the influence of the sun in bronzing the skin, and no one had ever dreamt of asserting that disorders of the supra-renal capsules were the only causes of increased deposit of pigment. There were, undoubtedly, many others. With due discrimination, however, there could be but little difficulty on the part of the trained observer in speaking confidently as to the particular form of bronzing which did really result from diseased capsules. He would

assert boldly that there was as good evidence in support of the belief that such bronzing as the patient before the Society exhibited was really dependent upon disease of the capsules, as could be adduced in favour of the connexion of any of our best acknowledged symptoms with their respective lesions. The pathognomonic indications of change in colour of the skin must be ascertained in each instance by noticing its intensity, the parts on which it commenced, its slowness of progress, and its concomitant symptoms. Above all, the existence of black stains on the mucous linings of the lips was of importance. To say that bronzing was a symptom which, carelessly observed, was very liable to lead to error, was to allege nothing whatever against its value when cautiously appreciated, or to derogate one iota from the worth of Dr. Addison's discovery. In adducing cases of the converse kind, those, namely, in which the supra-renal capsules were found disorganized, whilst no bronzing of the surface existed, Dr. Harley had also neglected to avoid a very palpable source of error. All such cases were examples of recent disease of the organs. Now, as bronzing required for its production a very prolonged interval, probably not much less than a year, it could not reasonably be expected in such cases. The patients died before it had time to appear. No single instance had, as far as he was aware, yet been recorded in which the disease of the capsules was such as to make it probable that it had been long present, or in which the constitutional symptoms had existed for more than a few months before death, where the bronzing had not been noticed in greater or less degree.

DR. HARLEY did not deny the importance of the functions the supra-renal capsules had to perform; in fact, no organ of the body could be considered unnecessary. Still it could not be said that they were indispensable to life, for patients often lived for some time after the arrest of those functions. In the case of Professor Walshe's patient, which he had recently brought before the Pathological Society, the medullary substance of both organs was totally replaced by tubercle, and even the cortical substance had almost entirely disappeared, for only here and there could traces of the columnar cell masses be detected. No doubt in that case the function of the capsules had been temporarily performed by some other organ. The capsules could certainly be removed from the lower animals without the destruction of life: he had now alive and well a rat from which he extirpated the supra-renal bodies and spleen six months ago. Brown-Séquard, in a paper recently read to the French Academy, had stated that the reason why M. Philipeaux's and his (Dr. Harley's) animals lived after the removal of the capsules was that they were albinos; but this was not the case, for he had kept alive for several months animals that were not albinos. A piebald rat which he once had in his possession became quite fat and healthy after the removal of both supra-renal capsules, but died subsequently from the effects of the removal of the spleen. In cases where death had followed the removal of the capsules, it might in the majority of cases be traced to the injury done to the solar plexus. It might be taken for granted, that the more intimate the connexion between the capsules and the ganglions, the more fatal were the operations; and the farther removed the capsules were from the ganglions the more successful was the result; for instance, the removal of the capsules from the guinea-pig was more fatal than from the dog, from the dog than from the cat, and from the cat than from the rat; and in the same species of animal the removal of the right capsule was more fatal than the removal of the left, from the same cause; the right capsule being as a general rule very much nearer to the solar plexus than the left. At present, however, there seemed to be no physiological evidence to show that either of the supra-renal capsules was absolutely essential to life, or had any direct connexion with the chromatogenous function of the skin.

DR. ADDISON said he hoped Dr. Harley would not continue to entertain the notion, that he attached extraordinary importance to the discoloration of the skin. The term "bronzed skin" did not originate with him. All he ventured to do was to describe the diseased condition that he met with; and the earliest indication to the eye was this discoloration of the skin. He believed the disease might occur, and had occurred, without any discoloration of the skin. A case occurred at Guy's Hospital, where all the symptoms were those indicative of the disease, and a physician there expressed his asto-

nishment that he should not have recognised it, notwithstanding the absence of the discoloration of the skin; and after death the lesion of the capsules was found. He should like this simple fact explained to him by the gentleman who spoke last:—He saw a patient who presented this peculiar discoloration of the skin: he offered no explanation as to whence, or how, or why it came. He observed associated with that discoloration a certain train and combination of general symptoms—a pearly eye, a feeble pulse, a disposition of strongly marked anemia, and a few other symptoms less constant and less urgent; and when he met with that combination he said, "There is a case in which you will find disorganization of the supra-renal capsules." The body was examined; no other organs were found diseased, but these organs were found in a state of universal suppuration. He did not profess to explain this; he knew no more about it than other people: but he believed, when the disease did occur in these organs, it led to these consequences and to inevitable death.

## THE PATHOLOGICAL SOCIETY.

TUESDAY, FEBRUARY 16.

Mr. SIMON, Vice-President, in the chair.

Dr. BRISTOWE showed organs from a case of

### FATAL ANÆMIA.

A young man, aged 24, was admitted at St. Thomas's Hospital with the account that he had been suffering from mild jaundice for four months. He had been liable to attacks of it for several years. He was pallid, feeble, and liable to giddiness and vomiting. The jaundice continued, but was never extreme. He had loss of appetite, and slight constipation of the bowels. His motions had contained bile throughout. He died from exhaustion nine months after the commencement of his illness. At the autopsy, which was most carefully conducted, no organic disease whatever could be found. The liver was a little enlarged and bile-stained, but otherwise quite healthy. The spleen, supra-renal capsules, and kidneys were healthy. Dr. Bristowe stated, that he felt much at a loss to explain the fatal cachexia which had existed in this case. It was one of a class, examples of which are every now and then met with, in which no organic lesion whatever can be discovered as explanatory of the symptoms.

Dr. THEOPHILUS THOMPSON remarked, that he should suspect some miasmatic or malarious influence existing at the home of the patient, and inquired whether he had been the subject of syphilis.

Mr. HUTCHINSON asked whether the thoracic duct had been dissected, so as to make it certain that it was not occluded, and also whether the pituitary body had been looked at.

Dr. BRISTOWE replied that the man had not had syphilis. He regretted that neither the thoracic duct nor the pituitary body had been examined.

Dr. BARKER showed a specimen of

### APOPLECTIC CYST.

A gentleman, aged 60, was attacked suddenly one night with severe cramp in the toes and fingers. This passed off, and no apoplectic seizure took place, nor did any paralysis result. Some weeks after this, and when again in good health, an epileptic seizure took place, and subsequently, after a considerable interval, a second and more violent one. He died eight days after the latter from erysipelas, consequent on the application of a blister to the nape. At the autopsy a large cyst was found between the posterior lobe of the left hemisphere of the brain and the cerebellum, which had evidently contained a large coagulum. The contained blood had been nearly absorbed, and thus it seemed certain that a large extravasation had at some distant period occurred, without causing apoplexy, or inducing paralysis. Dr. Barker related two other cases in which large extravasations of blood within the skull had occurred, while no apoplexy had taken place, and only very limited paralysis had existed.

Mr. WILLIAM ADAMS, without wishing to, in the least, question the accuracy of the description given, would remark that the large clots sometimes found within the skull, in cases in which no symptoms of apoplexy had been present, were often fungoid growths into which extravasation of blood had

occurred. He had seen several such, and they constituted an important class although, he believed, not described.

Dr. BRISTOWE next showed a specimen of

### CYSTS IN THE KIDNEY.

It was a good example of the minute microscopic cysts so often found in the kidney. It was brought forward not on account of its rarity, but in order to illustrate some points in the pathological genesis of the cysts in question. Scrapings from it which were under the microscope seemed, Dr. Bristowe thought, completely to disprove the assertion of Dr. Johnson that these appearances were in reality sections of tubes, and to show conclusively that they were true cysts. With regard to their original mode of formation he inclined rather to the view of Mr. Simon than to that of Dr. Johnson, and thought that there was more evidence in support of their being autogenous than resulting from dilatation of tubes. It was possible, however, that they might be formed in a sort of moniliform breaking up of the tubes into segments, each of the latter developing into a cyst. One thing was certain, that in parts where these microscopic cysts abounded, there the tubes were proportionally wanting. Dr. Bristowe added, that he had devoted much attention to the subject, and felt confidence in the accuracy of his conclusions. He should be glad if the specimen were referred to a committee.

The specimen was referred to Dr. Quain, Dr. Andrew Clark, and Dr. Wilks, for further report.

Mr. HENRY exhibited an

### ENLARGED SPLEEN OF A PIG.

It was three feet long, and weighed fifteen pounds. The average weight of the spleen of an animal of its size was about a pound. The pig had appeared to be in perfect health at the time when it was killed. It seemed when cut up to be in good condition, and no organs except the spleen were otherwise than healthy. The spleen appeared to be in process of fibroid degeneration. As far as he had inquired, he had not been able to ascertain that enlarged spleen was a common affection among pigs.

Mr. CHRISTOPHER HEATH showed a specimen of

### CANCER OF THE STOMACH AND ŒSOPHAGUS.

The specimen had been removed from a subject in the dissecting-room of the Westminster Hospital, and, unfortunately, the previous history of the case was wanting. On opening the abdomen, a tumour of about the size of a large chestnut was found attached to the lesser curvature of the stomach, near the Œsophagus, but not involving it. On section, it presented the appearance of a malignant growth, and this was confirmed by microscopic examination. It appeared to have been developed in the wall of the viscus, but did not involve its mucous coat. In a later period of the dissection there was found a malignant ulcer in the Œsophagus, about an inch above the diaphragm, measuring three inches in the vertical by two in the opposite direction. The tissues immediately surrounding it were considerably indurated, and it had produced such a narrowing of the canal, that a large quantity of food was contained in the ulcer. A careful dissection failed to discover any trace of disease in the other organs.

Mr. HEATH also showed a specimen of

### CANCER OF LIVER AND STOMACH, WITH PERFORATION.

The man was a patient under Dr. Ratcliffe's care in the Westminster Hospital; but as he died three days after admission, the notes of his case were necessarily meagre. He was 63 years of age, and was admitted February 9, suffering from great debility, and complaining of slight cough and some pain in the epigastrium. The abdomen was distended, and the bowels flatulent. There was no vomiting. He had been ailing for six months, with apparently dyspeptic symptoms, and gradually became so emaciated and debilitated as to cease work. He gradually sank, and died from asthenia.

*Post-mortem.*—The abdomen was found filled with fluid containing flakes of lymph in great abundance. On the lesser curvature of the stomach, close to the Œsophagus, was a mass of cancer as large as the fist, in the centre of which was a sloughy spot, through which perforation of the viscus had taken place. On opening the stomach, a large malignant ulcer, the size of the hand, was found in the corresponding position. There was no disease in the Œsophagus. The liver

was most extensively diseased, the left lobe being almost entirely converted into encephaloid cancer, and a large mass of the same disease being present in the right lobe. It is remarkable that there were no symptoms referable to cancer of the stomach; and the evidence of peritonitis was so slight, that there was no suspicion of perforation.

## ARMY MEDICAL AND SURGICAL SOCIETY.

Feb. 6, 1858.

SIR JOHN HALL, K.C.B. in the Chair.

THE Hon. Secretary, Mr. Mouat, read a most interesting and elaborate paper by Dr. Lawson, Deputy-Inspector of Hospitals, "On the Yellow Fever Epidemic of 1856, at Newcastle, Jamaica." The paper was amply illustrated by cases, tables, a plan-drawing of the mountain ridges on which Newcastle stands, and a photograph of the barracks, etc., showing their position and distribution.

The most novel and interesting features connected with this report, which is much too long to abstract or abridge without destroying its integrity, are the following:—

1. It denies the conclusions arrived at by Baron Humboldt, Dr. Fergusson, and others, of the possibility of yellow fever occurring at an elevation of 4000 feet above the level of the sea. On this point the author states:—"An opinion has long prevailed that the severe forms of tropical fever could not originate or spread at a considerable elevation above the sea."

The grounds for this opinion seem to be the statement of Humboldt, that yellow fever was confined to the low country on the coast near Vera Cruz, and that it did not pass the farm of L'Encero, elevated 3045 English feet above the sea, "the heat there being insufficient to develop its germ;" and that of Fergusson, with reference to the varieties of fever occurring at different elevations in St. Domingo.

The remarks of these authorities were no doubt correct for the time and place; but it must not be thence concluded that all the conditions requisite for the production of these forms of fever, except that of suitable elevation, were present in the cases they adduce. Their deductions, therefore, require to be applied cautiously to other localities, and may render certain modifications of the conditions henceforward inapplicable to the same localities at another time.

2. It disposes satisfactorily enough in the present epidemic of the non-contagious nature of yellow fever. The following are the grounds for this conclusion:—That out of 156 men, taken indiscriminately from the different barrack-rooms, very few of whom could have had yellow fever before, and who afford 210 instances of exposure for 24 hours to the emanations from the sick in the fever wards, that only 8 were subsequently affected with fevers of any sort, of whom 3 died; while from the remainder of the troops in the cantonment, amounting at the commencement of the epidemic to 523, there were 89 attacked with fever, of whom 38 died. Putting these numbers in the form of a centesimal ratio, for the sake of comparison, they stand thus:—

	Total Strength.	Attacked per cent.	Died per cent.	Died per cent. of those attacked.
Men who attended Fever cases ... ..	156	5.1	1.9	38.0
Men who did not attend Fever cases ... ..	523	17.0	7.3	43.0

It likewise disproves the commonly received opinion, that a temperature of at least 80 degs. Fahrenheit is necessary to develop its form, whatever that may be.

This fact is illustrated by the following table of temperature:—

1856.	6 a.m.	2 p.m.	6 p.m.	Mean.
	Deg.	Deg.	Deg.	Deg.
July ... ..	67.5	74.2	72.5	71.4
August ... ..	67.1	73.8	72.0	71.0
September ... ..	67.4	73.7	71.8	71.0
October ... ..	65.3	72.7	70.1	69.4
November ... ..	62.2	69.2	64.2	66.6
December ... ..	60.1	68.8	63.5	65.3

the disease having prevailed as an epidemic at Newcastle with a mean of 10 degs. lower, and continued until the mean temperature had fallen 5 degs. more.

The author confirms the fact previously noticed, of the suspension of yellow fever under the influence of heavy rain, which has been observed in every epidemic at Sierra Leone, at which time the fever assumed a purely remittent type. He inquires, "Can this be explained on the assumption of yellow fever being propagated by specific contagion?"

He concludes by stating, with reference to Newcastle, that the above facts seem to leave open no other inference than that the yellow fever there in 1856 arose from local causes.

Whether similar causes were in operation there in other years, and if so, why they did not lead to a similar result, are questions that the present state of our information does not admit of being answered. It seems, however, that in addition to the ordinary local causes of disease, an epidemic constitution is necessary to account for the prevalence of fever.

Two out of three of the Medical officers present were of opinion that it arose from local causes, and one that it might have been imported.

A short discussion took place, in which Staff-Surgeons Matthews, Hanbury, and Wm. Mouat took part. After which the President proposed a vote of thanks to the author for his very interesting and able paper.

It was announced by the Hon. Secretary that, with the sanction of the Director-General, the next meeting of the Society will take place at No. 6, Whitehall-yard.

## WESTERN MEDICAL AND SURGICAL SOCIETY.

JANUARY 15, 1858.

DR. SEATON, Vice-President, in the Chair.

MR. JAMES LANE read a paper on

### "SOME POINTS CONNECTED WITH SYPHILIS AND ITS TREATMENT."

Having alluded to the fallacy which existed formerly in the Profession respecting the curability or non-curability of syphilis by mercury being a test for the disease, he admitted that many cases, under favourable circumstances, might be cured without the administration of a particle of the mineral, and considered that where it was administered we should have a clear understanding of the object we have in view. 1. Is it to expedite the healing of the sore? M. Ricord's experience was that, used indiscriminately, it took longer to cure cases of syphilis with than without mercury; and M. Devergie's observations tended to the same result. In certain cases, however, as where much induration exists, general experience agreed that mercury is useful. 2. How far does the mercurial treatment of the primary disease influence the frequency of the secondary symptoms? The records of the Army Surgeons, given by M. Bacot, and including a large number of cases, show that the proportion in which secondary symptoms occur after the use of mercury and without the use of mercury is as 1:7½. As, however, a large number of cases, if left to themselves, as proved by experience, would never be followed by contamination of the system even if no mercury were given, it becomes important to attempt to classify the two kinds of cases. Hence M. Ricord has designated the indurated sore as the infecting, and the non-indurated sore the non-infecting form of the disease, and thinks that as soon as induration has taken place the disease no longer is a local one, but that the induration is the first expression of a diathesis and the commencement of the constitutional disease; and in his last work has broached the doctrine, that these two forms are different diseases, each capable of propagating themselves. Having recognised the value of induration as a sign of the probable occurrence of constitutional symptoms, it is necessary also to recognise the induration in its proper character, as distinguished from that the result of irritation, whether from the friction of the clothes or the use of caustics. The true induration is *sui generis*, giving the sensation of an elastic cartilaginous tissue, which does not resemble at all that produced by the hard œdema of inflammatory exudation, or the thickened tissue of a cicatrix. He then alluded to Mr. Lee's view respecting the manner in

which the indurated sore more especially affected the system. He seemed to think that in the non-indurated sore the poison was excreted by the ulcerative inflammation, while in the other kind adhesive inflammation was set up, and that the blood became contaminated in its circulation through the effused lymph. Be that as it may, the fact was established that indurated ulcers were very soon followed by the secondary symptoms. With respect to the non-indurated sores, it is certain that mercury does not accelerate their healing, and as secondary symptoms are less frequent after their occurrence in a majority of the cases, and though there may be no necessity for its general use, yet we should bear in mind that in some few cases the venereal poison may be and is absorbed into the system and so produce secondary symptoms. This then being the case, the author considered that even in such cases a mild course of mercury was advisable, and offered much more general chance of success than any other mode of treatment, though in recommending it he, of course, advised its sparing use, together with ordinary precautions during its exhibition. Though the same results could be brought about by purgatives, diuretics, low diet and diaphoretics, yet he thought that as mercury is regarded as one of our chief evacuants, it should be used in the majority of cases, especially as he considered the general health of the patient would suffer less by the latter treatment judiciously adopted than by the former. An exception obtains, however, in cases of phagædenic ulceration, which occurs in broken down and dissipated constitutions, and depends upon some state of constitution of the recipient. Such ulcerations spread rapidly under the use of mercury and require treatment by tonics, stimulants and sedatives. Such sores are seldom followed by constitutional infection, the phagædæna recurring soon after the establishment of the sore, the part affected being removed by destructive ulceration before time has occurred for the necessary absorption of the poison. If it occur late absorption will take place and secondary symptoms supervene, and if they do, they are severe; superficial and destructive ulcerations (as rupia) being liable to occur, and the palate and pharynx being apt to become involved in the destruction of tissue. Can the secondary symptoms be communicated to another individual without the antecedence of primary symptoms in the person receiving the pox infection! As the secondary disease cannot be inoculated through blood or purulent matter, M. Ricord will only admit communication of secondary symptoms to occur under circumstances of hereditary transmission; he admits that a diseased father may beget a diseased ovum, and that the diseased fœtus may convey *in utero* the disease to the mother, though after birth the infection can only be contracted through the medium of the primary ulceration. This view of the case is, nevertheless, denied by Mr. Wallace and Mr. Wilson, and the occurrence of secondary symptoms in the wife, in connexion with them in the husband, at the time of marriage, and without the supervention of pregnancy to complicate the question, would seem to establish possibility of the contamination? In support of this view Mr. Lane brought forward several cases which tended materially to refute the theory of M. Ricord, and to establish the contrary opinion before expressed, that secondary symptoms can be propagated from the husband to the wife without the supervention of pregnancy, and that in such cases the transmission of the disease can only be otherwise explained by supposing that the female had been previously affected with the primary sore, an explanation which we were not warranted in receiving in far the majority of cases.

The Society, after some discussion, especially on the latter point mentioned, then adjourned.

## PARLIAMENTARY INTELLIGENCE.

### HOUSE OF COMMONS.

#### MORTALITY IN THE ARMY.

Mr. LAURIE asked the Under-Secretary for War what steps are to be taken to remedy the great mortality of the army, especially of the Foot Guards, the report of the Commissioners recently presented proving that two-thirds of the deaths are from consumption and other diseases in consequence of the crowded state of the barracks of the metropolis.

Lord PALMERSTON.—My noble friend at the head of the

War Department being quite aware of the great defects in the arrangements of the existing barracks and hospitals, and thinking that improvements might be made therein greatly to the benefit of the soldiers, recommended the appointment of a commission to inquire into the subject. That commission, at the head of which was my right hon. friend the member for Wiltshire, has made a very valuable report, which is now in the hands of the printer, and will shortly be laid before this House, but the time since its presentation has been so short that the Government have not yet come to any determination respecting the step to be taken. The matter is, however, far too important and too interesting to the country to be allowed to remain without due attention. (Hear, hear.)

#### MEDICAL CHARITIES (IRELAND) ACT AMENDMENT BILL.

Mr. FITZGERALD obtained leave to bring in a Bill to amend the laws in force for the relief of the destitute poor in Ireland, and to amend an Act of the 14th and 15th years of Her Majesty, providing for the better distribution, support, and management of medical charities in Ireland.

#### MILITARY SURGERY.

In answer to Mr. BLACK, who asked whether a professor had been appointed to the chair of military surgery in Edinburgh,

Sir J. RAMSDEN said that no such appointment had been made. His noble friend at the head of the War Department had intended to appoint a professor to that chair, but it became known that the medical commission which was then sitting was about to recommend the discontinuance of all these local professorships, and thereupon his noble friend suspended his intention of making the appointment.

#### MORTALITY IN THE GUARDS.

Captain ANNESLEY asked whether the Government had received any report from the regiments of Foot Guards which proved that the mortality, instead of being 22 per 1,000, is little more than half that amount in those regiments.

Sir J. RAMSDEN said that such a return had just been sent in to the War-office, but he had not yet had time to give it more than a cursory examination. It was drawn up in an entirely different form from the tables published by the Medical Commission, and as far as he could judge it was much more favourable than those tables. That might perhaps be accounted for in this way, that the calculations of the commissioners were based upon returns for the 15 years ending 1853, while the report recently sent in only referred to the 18 months ending the last month.

#### PUBLIC HEALTH ACT AMENDMENT BILL.

Mr. COWPER suggested that the House should agree to the second reading of the Bill, on the understanding that the discussion should be taken upon going into committee.

Mr. PALK could not agree to the suggestion, as his objections were to the principle of the Bill.

Mr. LOCKE said that this Bill had become a regular Parliamentary nuisance. (Hear, hear.) He had waited several nights for it to come on, and he thought some determination ought to be come to as to whether the Bill was to be proceeded with or not. At present the right hon. gentleman had not given the house any explanation at all of the provisions of the Bill.

Lord PALMERSTON hoped that when the Bill came to be discussed, it would be discussed without the prejudice which was endeavoured to be raised against it. It was a measure deeply involving the interests of the people, as it was addressed to the prevention of diseases which involved a greater loss of life than any war in which the country had been engaged.

Sir G. PECHELL hoped a day would be fixed for the discussion.

Mr. HENLEY said that as the Bill was of the importance which the noble lord represented, it was the noble lord's duty, as leader of the House, to fix a proper time for the discussion.

#### LUNATIC ASYLUMS (IRELAND).

Mr. BLAND asked the Chief Secretary for Ireland whether it was his intention to introduce any measure this session for the management of lunatic asylums in Ireland?

Mr. H. HERBERT (who was almost inaudible in the gallery) was understood to say that he could not make any promise on the subject.

#### MORTALITY IN THE GUARDS.

Captain ANNESLEY moved an address for a copy of the report of the medical officers of the Foot Guards which stated

the average mortality in that brigade. He anticipated that the document in question would show results different from those contained in the recently published report of the commission.

**MR. S. HERBERT.**—If the last two years are included, I propose to add a return of the number of non-commissioned officers and men discharged from the Foot Guards during the same period, distinguishing those discharged of reduction as being under height, those discharged upon the recommendation of the medical officers, and those invalided. We shall thus, I think, bring out the real facts of the case. I wish to repeat that this report is a great weapon in the hands of the army, and of those who are its well-wishers, who desire to put an end to evils of which, to my certain knowledge, there have been loud and long complaints. (Hear, hear.)

**Colonel PENNANT** described the ill-ventilated and crowded state of the barracks for the Guards in former days, and said that the expenditure necessary for the substitution of new barracks for those which were now complained of, was then objected to on the plea that it was proposed to build gorgeous palace for the troops.

The motion as amended was then agreed to.

## MEDICAL NEWS.

**ROYAL COLLEGE OF SURGEONS.**—The following gentlemen were admitted Fellows at a meeting of the Council on Thursday, February 11th:—

**CARTER, H. F.,** Brighton; diploma of membership dated April 15, 1842.

**DAVEY, H. W. R.,** Worthing; December 3, 1819.

**ESSEBY, THOS. A.,** Swansea; May 22, 1839.

**JONES, Thomas Stead, Ely;** May 17, 1811.

**HADEN, Francis Seymour,** Sloane-street; June 27, 1842.

**HALL, Edward,** Dalton in Furness; February 27, 1829.

**LOCKHART, William,** Shanghai; April 29, 1834.

**LOWE, Wm. Thos.,** Canonbury-square; July 30, 1830.

**MORGAN, Howell,** Dyfynog, Brecon; August 26, 1842.

**PEGGE, John,** Manchester; April 1, 1842.

**RODEN, William,** Kidderminster; November 25, 1842.

**ROWLANDS, James,** Carmarthen; May 20, 1842.

**SMITH, Robert Wm.,** Winchester; June 6, 1834.

**STEDMAN, Silas Stilwell,** Brighton; January 14, 1842.

**WOOD, William,** Wakefield; June 26, 1842.

**WYBRANTS, Jonathan,** Shepton Mallet; August 27, 1839.

**APOTHECARIES' HALL.**—Names of gentlemen who passed their examination in the Science and Practice of Medicine, and received Certificates to Practise, on February 11, 1858:—

**GARNEYS, THOMAS,** Bungay, Suffolk.

**TAYLOR, RICHARD,** Charlbury, Oxon.

**THANE, CHARLES SEYMOUR,** Canonbury.

## DEATHS.

**ARROWSMITH.**—On the 13th inst. William Arrowsmith, M.R.C.S. Eng. 1840, youngest son of C. Arrowsmith, Esq., of Burton-crescent.

**BATE.**—At Plymouth, George Bate, aged 24.

**BONE.**—On the 13th inst. in Edinburgh, Hugh Bone, M.D., Inspector-General of Army Hospitals, aged 81.

**BORRUS.**—M. Borrus, the prior of the Hospice of the Simplon, has just died, aged 70. The Hospice of the Simplon is an establishment attached to that of St. Bernard. The prior was well known to travellers, as he had passed forty-seven years in these hospices, having during twenty-three years had the direction of that of the Simplon.

**KNOWLES.**—On the 12th inst., at Batley, William Knowles, M.R.C.S. Eng., and L.S.A. 1846.

**PULLEYNE.**—Feb. 7, at East Dereham, Walter M. Pulleyne, L.S.A. 1844.

**ROLPH.**—On the 17th inst., at Portsmouth, of apoplexy, Thomas Rolph, Esq., M.D., Surgeon, aged 57 years.

**STELFOX.**—Feb. 7, at Leigh, Thomas Stelfox, of King-street, Manchester.

## APPOINTMENTS.

**Dr. CHARLES WARDEN** has been elected Honorary Surgeon to the Birmingham General Dispensary.

In pursuance of an Act passed in the third year of the reign of his late Majesty King William the Fourth, entitled "An Act for Regulating Schools of Anatomy," the Right Hon. Sir George Grey, Bart., Her Majesty's Principal Secretary of State for the Home Department, has appointed Charles Hawkins, Esq., to be an Inspector of Anatomy in England and Wales, in the room of John Bacot, Esq., resigned. The salary is £100 per annum, and is limited to that sum by the Act. The sooner this clause in the Act is amended the better.

**UNIVERSITY OF DUBLIN.**—At the Spring commencement held as usual, on Shrove Tuesday, in the Examination Hall of Trinity College, the following Medical Degrees were conferred by the Right Hon. Francis Blackburne, Lord Justice of Appeal, Vice-Chancellor of the University. M. D.—John R. Kinahan. M. B.—Edward P. Wright; Richardson King; Benjamin Bruland; William H. Pickford.

**SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN IN LONDON AND ITS VICINITY.**—The seventieth anniversary of this Society took place on Wednesday the 10th inst., when a numerous assemblage met at dinner at the Freemasons' Tavern to celebrate the first public appearance of the new President, Thomas Arthur Stone, Esq., whose energies have for many years been unreservedly given to this Society. The memory of the late most worthy President, Sir Charles M. Clarke, Bart., M.D., having been drunk in solemn silence, the toast of the three Medical Corporate Bodies was given, and responded to by the President of the College of Physicians, who expressed his opinion that the operations of this Society are conducted on the principles of true charity. The health of the new President was proposed by Sir Benjamin Brodie, who referred to the early years of his own career, when among his first pupils was enumerated Mr. Stone, one of the most zealous, to whose memoranda of cases Sir Benjamin even now refers with pleasure. Mr. Stone in reply drew attention to his predecessors in office, Sir George Baker, Bart., the first President; the most invaluable services of Mr. James Ware, who besides firmly establishing this Society, had also founded the School for the Indigent Blind; the Anatomist of world-wide reputation, Dr. Baillie; the classical Sir Henry Hallford; and lastly, the late Sir C. M. Clarke, of whom he had spoken previously. It would be his duty to emulate them in their zeal for the promotion of the Society, which it was shown, at a cost of about £300 a year, gives away in grants for relief above £1700—almost the whole of which is formed of a series of annuities paid half-yearly; and it is so arranged that within a very short period after the first application is made, a grant is issued. Donations to the amount of £200 were announced.

**PRIZES AT THE ACADEMIE DES SCIENCES.**—Among the prizes accorded by the Académie des Sciences, at its anniversary last week, were the following:—2500 francs to M. Broca for his work on Aneurism; 2500 francs to M. Morel for his work on Degenerescence; 2500 francs to M.M. Delafond and Bourguignon for their researches on the Itch in Animals; 1500 francs to M. Bertillon for his Statistical Conclusions against the Detractors of Vaccination; and 1500 francs to M. Fonsagrives for his work on Naval Hygiene.

**LONDON WATER.**—The quantity of impurity in every gallon of the water supplied by the metropolitan water companies was found by Dr. Robert Dundas Thomson, of St. Thomas's Hospital, to be, during the month of January, as follows:—

Companies.	Total Impurity. Gra.	Organic Impurity. Gra.
Chelsea . . . . .	21.56	1.08
West Middlesex . . . . .	20.88	2.05
Grand Junction . . . . .	20.72	1.60
Lambeth . . . . .	19.84	2.40
Southwark . . . . .	21.28	.92
East London . . . . .	23.04	1.76
Kent Company . . . . .	28.48	4.56
Plumstead . . . . .	20.16	2.28

There are slight differences, it will be observed, in the constitution of the waters from month to month, as might be anticipated. Plumstead water, from the chalk, is most steady in its organic matter, which appears to differ from that of the other waters in being incapable of germination.

## VITAL STATISTICS OF LONDON.

Week ending Saturday, February 13, 1858.

## BIRTHS.

Births of Boys, 948; Girls, 893; Total, 1848.  
Average of 10 corresponding weeks, 1848-57, 1675.

Whole amount of rain in the week ... ..	0.08 in.
Amount of horizontal movement of air in the week ... ..	855 miles

## TO CORRESPONDENTS.

D. P. M.—It is difficult to answer the question without knowing the exact terms on which the Medical man and patient had been, and the station, profession, etc. of the patient.

Mr. Butcher's letter, in reply to one inserted last week as to the originality of the bow-saw used in excision of joints, arrived too late for insertion this week. It shall appear next week.

Mr. Brentwood.—It is usual for gentlemen who have passed the first M.B. examination of the University of London to use the letters M.B. after their names, and to have them inserted with other qualifications in the Directory.

## CHLORODYNE.

Dr. Medlock has requested us to insert the following statement:—

"In the blue bottles in which chlorodyne is sold it has the appearance of a 'ponderous dark liquid,' but if transferred to a white bottle, it is seen to separate into two strata, the upper one colourless, and the lower one of a dark brown colour. On distilling a portion of chlorodyne from a water-bath, a colourless distillate was obtained, amounting to nearly half the bulk of the substance distilled. This distillate separated into two strata, the upper one consisting of an aqueous solution of prussic acid, and the lower of chloroform. The dark residue left after separating the prussic acid and chloroform was found to consist of liquorice, capsicum, perchloric acid, and morphia, or an analogous base, the whole being flavoured with peppermint.

The examination we have made of chlorodyne enables us to state that it is not what it is represented to be, that is, a perchlorate of a new base. Perchloric acid, as is well known to every chemist, will combine readily with any of the vegetable bases. The solution, however, will be colourless, and will not separate into two strata; moreover, it is a new fact in chemistry to find a perchlorate of a vegetable alkaloid yielding on analysis prussic acid, oil of peppermint, extract of liquorice, capsicum, and morphia, besides half its weight of chloroform."

Inquirer.—According to the advertisement which appeared in our number of January 30, the Carmichael Prizes are open for competition to all without restriction. A reference to our past volumes, and to Parliamentary documents, will afford the best information on the subject of the Prize Essays.

Mr. Rogers informs us that the use of gutta-percha as a frame for artificial teeth has been in use for some years past.

Francis.—The paper has been delayed only by others received previously. It shall be inserted as soon as possible.

## THE MUSEUM ASSISTANT AT THE COLLEGE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Knowing the interest you feel, and the just view you take of all that belongs to the Profession, I have ventured to trouble you with this letter to inform you of the manner in which the Second Assistant in the Museum of the College of Surgeons has been filled up by the appointment of Dr. Murie. There were several candidates, and we were informed that

one of us would be selected from an examination of testimonials, and by personal inquiries. I learnt that my testimonials were the best (I enclose you a copy); but some days afterwards we had notice sent that four of us had been chosen to undergo a dissectional examination. This lasted two days; and I was then informed that it was the opinion of the members of the Museum Committee that my dissections were the best. Nevertheless they have appointed Dr. Murie, who is not a member of the College; and it appears that one of the Committee wrote for him to come as a candidate, so that the remainder of us were tempted to take a great deal of trouble, with no possibility of success.

The appointment has been made a week to-day, yet I have had no notice sent me of it, and have only learnt it by accident.

I must apologise for addressing you so much at length, but as you will probably notice the appointment in your Journal, I was desirous of making you acquainted with the circumstances first. I have written to the Council demanding an explanation, and will send you an account of its answer.

I am, &amp;c.

GEORGE W. LAWRENCE, M.B. Lond.  
Late House-Physician to King's College Hospital.

Camberwell House, Feb. 18, 1858.

## DIETARY AT AN HOMOEOPATHIC HOSPITAL.

We borrow the following lines from the *Edinburgh Medical Journal*:—

Take a robin's leg  
(Mind it the dramatick merely),  
Put it in a tub  
Filled with water nearly;  
Set it out of doors,  
In a place that's shady;  
Let it stand a week  
(Three days if for a lady).  
Drop a spoonful of it  
In a five-pail kettle,  
Which may be made of tin  
Or any baser metal;  
Fill the kettle up,  
Set it on a boiling;  
Skim the liquor well,  
To prevent its clogging;  
One atom add of salt,  
For the thickening one rice kernel,

And use, to light the fire,  
"The Homoeopathic Journal."  
Let the liquor boil  
Half-an-hour, no longer,  
(If 'tis for a man  
Of course you'll make it stronger).  
Should you now desire  
That the soup be flavoured,  
Stir it once around  
With a stalk of savoury.  
When the broth is made,  
Nothing can excel it;  
Then three times a day  
Let the patient swallow it;  
If he chance to die,  
Say 'twas Nature did it;  
If he chance to live,  
Give the soup the credit.

## COMMUNICATIONS have been received from—

MR. LANGSTON PARKES, Birmingham; Dr. R. D. THOMSON; Dr. BALFOUR;  
Dr. MERRIMAN; Mr. WILDE, Dublin; Mr. BARRON, Sunderland; Dr.

ident in India; Mr. ROGER SALTER. }

## APPOINTMENTS FOR THE WEEK.

Feb. 20. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's  
2 p.m. Charing Cross, 1 p.m.

MEDICAL SOCIETY, 8 p.m.: Dr. William Camps, "On the lately prevailing  
Diphtheritic Affection."

ROYAL INSTITUTION, 3 p.m.: Professor Bloxam, "On the Chemistry of the  
Elements which circulate in Nature."

GUY'S PHYSICAL SOCIETY, 7 p.m.: Mr. Tuck, "On Sciatica."

## 22. Monday.

Operations at the Royal Free Hospital, 1 p.m.; Metropolitan Free Hospi-  
tal, 2 p.m.; Orthopaedic Hospital, 3 p.m.

## 23. Tuesday.

Operations at Guy's, 1 p.m. Westminster, 2 p.m.

ROYAL INSTITUTION, 3 p.m.: Professor Huxley, "On Biology."

ROYAL MEDICAL AND CHIRURGICAL SOCIETY, 8½ p.m.: Mr. F. W. Mac-  
kenzie, "On the Action of Galvanism upon the contractile Structure  
of the Gravid Uterus." Mr. Cooper Forster, "On the Direction of the  
Nutritious Foramina of the long Bones."

ZOOLOGICAL SOCIETY, 9 p.m.

## 24. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m.  
Orthopaedic Hospital, 3 p.m.

ROYAL COLLEGE OF PHYSICIANS, 4 p.m.; Guelstonian Lectures—Dr. Sy-  
monds, "On Headache."

GEOLOGICAL SOCIETY, 8 p.m.

## 25. Thursday.

Operations at St. George's, 1 p.m.; Middlesex, 12½ p.m.; Central London  
Ophthalmic, 1 p.m.; London, 1½ p.m.

ROYAL INSTITUTION, 3 p.m.: Professor Tyndall, "On Heat."

ROYAL SOCIETY, 8 p.m.

MEDICAL SOCIETY OF KING'S COLLEGE. Clinical Meeting.

## 26. Friday.

Operations at the Moorfields Ophthalmic, 10 a.m.; Westminster Oph-  
thalmic, 1½ p.m.; Great Northern, 2½ p.m.

ROYAL COLLEGE OF PHYSICIANS, 4 p.m.; Guelstonian Lectures—Dr. Sy-  
monds, "On Headache."

ROYAL INSTITUTION, 8½ p.m.; Professor Baden Powell, "On Rotatory  
Stability and its Applications, illustrated by the Apparatus of Profes-  
sor C. Piazzi Smyth."

## EXPECTED OPERATIONS.

Westminster Hospital.—The following operations are expected on  
Tuesday next, at 2 p.m.:—Stricture of urethra; extension of anchylosed  
knee; fatty tumour of thigh: by Mr. Holt. Wutzer's operation for radical  
cure of hernia; subcutaneous puncture of abscess: by Mr. Holthouse.

# ROYAL MEDICAL BENEVOLENT COLLEGE, (INCORPORATED BY ACT OF PARLIAMENT.)

*Patron.*—HER MOST GRACIOUS MAJESTY THE QUEEN.

*President.*—THE RIGHT HONOURABLE THE EARL MANVERS.

*Visitor.*—THE LORD BISHOP OF WINCHESTER.

*Treasurer.*—JOHN PROPERT, Esq.

The Council of the Royal Medical Benevolent College have the pleasure to inform the Governors and Friends of the Institution that the SIXTH ANNUAL FESTIVAL will take place at the FREEMASONS' TAVERN on WEDNESDAY, the 24th of March next, when the Right Honourable the LORD STANLEY, M.P., has kindly consented to take the Chair.

The following Noblemen and Gentlemen have undertaken to officiate as Stewards on the occasion :—

The Right Honourable the Earl of Huntingdon.  
The Right Honourable the Viscount Boyle.  
Sir John Forbes, M.D. D.C.L. F.R.S., Old Burlington-street.  
The Rev. John Jennings, M.A., Canon of Westminster.  
The Rev. P. Melancthon Holden, St. Paul's Chapel, Gt. Portland-st.  
Michael T. Baas, Esq., M.P., Burton-on-Trent.  
H. Wentworth Acland, M.D. F.R.S., Oxford.  
J. D. Allcroft, Esq., Wood-street, Cheapside.  
Henry Allsop, Esq., Burton-on-Trent.  
Richard Bagge, Esq., Gaywood Hall, Lynn.  
Henry Bennet, M.D., Grosvenor-street.  
Henry Blonkarne, Esq., Dowgate-hill.  
George Bottomley, Esq., Croydon.  
R. Willson Brown, Esq., (Hon. Local Sec.,) Bath.  
Charles Browning, Esq., Dorset-place.  
Walter Bryant, Esq., Bathurst-street, Hyde-park.  
William Carr, Esq., (Hon. Local Sec.,) Blackheath.  
Nathaniel Clifton Esq., Cross-street, Islington.  
Edward N. Clifton Esq., Russell-place, Fitzroy-square.  
Edward Cock, Esq., Guy's Hospital.  
Charles Collambell, Esq., (Hon. Local Sec.,) Lambeth terrace.  
Thomas R. Colledge, M.D., Cheltenham.  
George Cooper, Esq., (Hon. Local Sec.,) Brentford.  
Charles Cotton, M.D., Lynn.  
C. Iderton Croft, Esq., Lawrence Pountney-hill.  
Henry Curling, Esq., Ramsgate.  
George Thomas Dale, Esq., Pembroke-place.  
William Dalton, Esq., (Hon. Local Sec.,) Cheltenham.  
Francis Davies, Esq., (Hon. Local Sec.,) Peabrook.  
Horatio G. Day, Esq., (Hon. Local Sec.,) Isleworth.  
Charles Drage, M.D., (Hon. Local Sec.,) Hatfield.  
Frederick Du Cros, Esq., The Grange, Kingston.  
Robert Dunn, Esq., Norfolk-street.

Richard D. Edgcombe, Esq., Shaftesbury-crescent.  
George Fincham, Esq., Marlborough-hill.  
John W. Fisher, M.D. Grosvenor-gate.  
Harry Leeke Gibbs, M.D., Exeter.  
Frederick Goodchild, M.D., Princess's-terrace.  
Charles Gardiner Guthrie, Esq., Pall Mall East.  
Henry Hancock, Esq., Harley-street.  
Richard Hassall, M.D., Richmond.  
John Vincent Hawkins, M.D., Lynn.  
Francis Hird, Esq., Clifford-street.  
W. C. Hoffmeister, M.D., (Hon. Local Sec.,) Cowes.  
George C. Jonson, Esq., Eaton-place South.  
T. Masters Kendall, Esq., (Hon. Local Sec.,) Lynn.  
Edward F. Leake, Esq., F.L.S., St. George's-road,  
J. C. W. Lever, M.D., Wellington-street.  
Charles F. J. Lord, Esq., Hampstead.  
D. B. Orridge Esq., Bucklersbury.  
Thomas Paget, Esq., Leicester.  
George Pinckard, Esq., St. James's-square.  
J. J. Power, M.D., (Hon. Local Sec.,) Maidstone.  
John Propert, Esq., New Cavendish-street.  
Joseph Ridge, M.D., Dorset-square.  
William Sankey, Esq., (Hon. Local Sec.,) Dover.  
D. Scannell, Esq., Chapel-street, Belgrave-square.  
J. O. Smetham, Esq., Mayor of Lynn.  
Thomas H. Smith, Esq., (Hon. Local Sec.,) St. Mary Cray.  
William E. Snow, Esq., Tredgar square.  
Henry Stary, Esq., Paragon, New Kent-road.  
Somerset Tibbs, Esq., Cheltenham.  
Richard Tippetts, Esq., Dartford.  
Francis Webb, Esq., Chancery-lane.  
Erasmus Wilson, Esq., F.R.S., Henrietta-street.  
R. Stanton Wise, M.D., (Hon. Local Sec.,) Banbury.

By order of the Council,

ROBERT FREEMAN, Secretary.

HERBERT WILLIAMS, Assistant Secretary.

Office, 37, Soho-square, London, February 16, 1858.

## Society for the Relief of Widows and ORPHANS OF MEDICAL MEN IN LONDON AND ITS VICINITY.

Instituted 1788.  
The Members are reminded that a Quarterly Court of Directors will be held on the 3rd of March, at which Candidates for admission into the Society can be proposed. It is desirable that the form of proposal be filled up and forwarded to the Secretary a few days before the meeting. All legally-qualified Medical Practitioners, residing in any part of the county of Middlesex, or within seven miles of the General Post-office in St. Martin's-le-Grand, are eligible, and the benefits of the Society are restricted to the families of deceased members of not less than two years' standing.

S. W. J. MERRIMAN, M.D., Secretary.

Barners-street, February 16, 1858.

The Secretary attends every Wednesday and Friday from 4 to 5 p.m.

## Leeds House of Recovery. — The

office of RESIDENT APOTHECARY to this Institution being vacant by the resignation of Mr. Barrow, his successor will be appointed on Thursday, the 18th of March, at 12 o'clock. It is required that he should be a Licentiate of the Apothecaries' Company, not under twenty-five years of age; that he shall devote his entire time to the duties of his office, including those of Secretary. Salary £100 per annum, with board, lodging, and washing. The fullest satisfaction will be required by testimonials and otherwise, and no one will be appointed without a personal interview. Testimonials as to character and professional acquirements must be forwarded to the undersigned at the Institution at least one week previous to the election.

J. C. BARROW, Secretary.

## Bank of Deposit, Established A.D. 1844.

3, PALL MALL EAST, LONDON.

Parties desirous of investing Money are requested to examine the Plan of the Bank of Deposit, by which a high rate of interest may be obtained with perfect security.

The Interest is payable in January and July.

PETER MORRISON, Managing Director.

Forms for opening Accounts sent free on application.

## Blenheim Free Dispensary, 84, Port-

LAND-ROAD W.—The office of PHYSICIAN to this Institution being now vacant, Gentlemen desirous of the appointment are requested to apply. Candidates must be members of the Royal College of Physicians of London. Letters of application and Testimonials to be sent to the Hon. Secretary on or before Thursday, February 25.

By order of the Committee,

J. L. SIORDET, M.B. L.R.C.P., Hon. Sec.

6, Holles-street, Cavendish-square, W., February 12, 1858.

## Blenheim Free Dispensary, 84, Port-

LAND-ROAD, W.—Wanted a DISPENSER. Testimonials and Certificates of good moral character to be sent to the Hon. Secretary on or before Thursday, February 25.

By order of the Committee,

J. L. SIORDET, M.B. L.R.C.P., Hon. Sec.

6, Holles-street, Cavendish-square, W., February 12, 1858.

## University of London.—Matriculation

EXAMINATION, 1858.—The ANNUAL COURSE of LECTURES and EXAMINATIONS in preparation for this Examination will commence at King's College, London, on Monday, February 22nd, 1858. For further particulars, apply to J. W. Cunningham, Esq., Secretary, King's College, London. R. W. JELF, D.D., Principle.

## Heigham Retreat, Unthinks - road,

NORWICH.—Private Asylum for the care and recovery of persons of the upper and middle classes suffering under mental derangement. The house is pleasantly situated, stands in extensive grounds, and is provided with every requisite comfort.

Visiting Physician—Dr. Copeman. Proprietors and Visiting Surgeons—Mr. Donald Dalrymple, Surrey-street; Mr. T. W. Croase, St. Giles', Norwich. Resident Proprietor and Surgeon—Mr. H. Landor. Matron—Mrs. Landor.

Terms may be obtained from the Proprietors, and from Messrs. Bircham, Dalrymple, and Drake, 46, Parliament-street, London.

**Wines from South Africa. — Port, SHERRY, etc., TWENTY SHILLINGS PER DOZEN.** These Wines, the produce of a British colony, which has escaped the vine disease (the vintage occurring in February may account for the same), are in consequence wholesome, and are warranted free from acidity and brandy, are admitted by Her Majesty's Customs at half-duty, hence the low prices. A Pint Sample Bottle of each for twenty-four stamps, Bottles included. Packages allowed for when returned.

"We have taken the trouble to try Mr. Denman's wines, and have also submitted them to several of the clergy, and the opinion formed is that they are worthy of being patronized."—Clerical Journal, October 22, 1857.

**EXCELSIOR BRANDY, Pale or Brown, 15s. per gallon, or 30s. per dozen.** Terms—Cash. Country orders must contain a remittance. Cheques to be crossed "Bank of London."

J. L. Denman, Wine and Spirit Importer, 65, Fenchurch-street. Counting-house entrance, first door on the left up Railway-place.

**PURE SPIRITS FOR THE FACULTY.**

**S. V. R. 56 o.p., 17s. 6d. net Cash.**

This quotation admits of neither credit nor discount, and 1s. per gallon must be added for packages, to be allowed on their return.

HENRY BRETT and CO., Old Fumival's Distillery, Holborn.

**S. Bowles, late Windsor & Co., Phial**

and BOTTLE MERCHANTS, Dealers in Druggists' Sundries, &c., 37, Bartholomew-close, City. The cheapest house in London for every description of Medical Glass of the best quality.

Samples and Prices forwarded free on application.

**For Use Medicinally, in all Diseases of**

the STOMACH, CHEST, etc., for dressing and deodorizing cancer and all foul wounds, for purifying sick chambers, for embalming the dead, etc., Mr. JASPER ROBERTS' PATENT CARBONIZED PEAT MOSS. The various kinds of powder and lozenges are prepared solely by the Health of Towns Improvement Company, Sole Wholesale Agent, Joseph G. Thompson, Esq., 2, Adelphi-place, London bridge, London, E.C., and 5, Donegal-square, Belfast; sold by Mr. W. L. Bird, Pharmacologist, 42, Castle-street, East, Oxford-street, W.; Mr. J. Johnson, Chemist, 123, Upper-street, Islington, N., London; Messrs. Bewley and Evans, Dublin; and all respectable Chemists. See extracts from publications on the subject, with the preparations.

**M. and R. Jewell beg to express their**

thanks for the encouragement they have received from the Medical Profession, and hope for a continuance of their favours at their Medical Glass and Bottle Warehouse, 53, Howland-street, Tottenham-court-road, where an extensive Stock is always kept on hand, at the lowest prices. Measures, Stopped Bottles, Pedestal Mortars, etc. etc. Orders punctually attended to. List of prices may be had on application.

**Kamala, a Powder obtained from the**

Capsules of Rottlera Tinctoria. Recommended as a remedy for Tape-worm; dose, half drachm to two drachms. See Medical Times and Gazette, May 2, and December 19, 1857.

ALLEN and HANBURY have a supply of the above-named Medicine. Price to Members of the Profession, 1s. per ounce; if by post, 1s. 4d. Tincture of Kamala, dose two to three drachms, price 1s. per ounce.

London: Plough-court, Lombard-street, E. C.

**NOTICE.**

**West-end Dispensing Establishment.**

In consequence of numerous errors which have occurred of late years through the carelessness of inexperienced Dispensers of Medicine, Messrs. CURTIS deem it expedient to assure the Profession and the Public that their method of transacting business precludes the probability of mistake, thus offering peculiar advantages for the Dispensing of Medicines, and fulfilling the best wishes and interests of the Profession and the Public.

**Messrs. Curtis continue to receive**

the most satisfactory results from Medical Men in favour of "P.A.S.M.A."

(Or, HEALING POWDER),

THE REMEDY FOR

EXCORIATIONS, BURNS, ULCERS, AND ERUPTIONS; ALSO, A PROPHYLACTIC OF ABRASIONS IN DELICATE, TENDER, AND IRRITABLE SKINS.

Messrs. CURTIS feel called upon to caution Medical Men against spurious imitations, and to inform them that the genuine is not a Metallic Preparation (nor a secret one), the Proprietors having informed the Profession of its exact composition.

Messrs. CURTIS also invite the attention of Medical Men to their NEW PHOSPHATE, or PULV. EBORIS PREPARATA, as prescribed by Dr. Stocker for Rickets, &c. &c. (Vide the Lancet, Dec 19, 1857.)

Also to their

EXPRESSED JUICES, LIQUORS, MEDICINAL EXTRACTS, TINCTURES, etc. etc.

CURTIS & CO., Pharmaceutical and Dispensing Chemists, (Wholesale and Retail), 15, Crawford-street, London. Established 1820

**Retreat for Ladies Mentally afflicted.**

**EARL'S-COURT HOUSE.**—This first-class Asylum for the reception of ladies only is situated at Old Brompton, the healthiest suburb of London, surrounded by six acres of ornamental grounds. Terms, regulated by the accommodation required, can be had on application or forwarded by post, with the highest testimonials from the leading members of the Medical Profession.

**Henry Simpson, 55, Strand, London,**

Surgical Instrument Maker to the Royal Naval Hospitals and Royal Navy, &c. &c. Manufacturer of every description of Surgical Instruments, Trusses, Bandages, Artificial Limbs, Splints, Crutches, Enemas and other Syringes, &c. &c. Best quality (only), at the most moderate prices. Manufacturer of all kinds of Cutlery. Prize Medal, 1851.

**St. Andrew's, Apothecaries' Hall.**

Dr. STEGGALL continues to give his Lecture and Private Tuition, preparatory to all Medical and Surgical Examinations. Apply before one or after three o'clock, at his residence, 2, Southampton-street, Bloomsbury-square.

**Carriages, New and Second-hand, of**

superior style, sterling quality, and finest finish at reasonable rates for cash, credit, job, or exchange. Circular of prices on application. Credit given when required. Buyers should take carriages on trial, with power to purchase by yearly payments, and thus prove them.

OFFORD'S PATENT MEDICAL-MAN'S BROUGHAM MANUFACTORY, 79, WELLS-STREET, OXFORD-STREET.

**Clarke's New PATENT PYRAMID NIGHT LAMPS.**

Tin at 1s., Lacquered or Bronzed, 1s. 6d. each.

For Burning the New Patent Pyramid Night Lights.

The most convenient, safe, and economical yet introduced.

Sold by all Grocers and Lamp Dealers, and Wholesale by

S. CLARKE,

55, ALBANY-STREET,

REGENT'S-PARK.

And by PALMER and CO., Clerkenwell, London, E.C.

**Great Saving in the Purchase of Six**

GROSS of NEW MEDICAL GLASS BOTTLES and PHIALS assorted to suit the convenience of Purchasers, at ISAACS & SON, Medical Glass Bottle Manufacturers.—London Warehouse, 6, Warren-street, Tottenham-court-road.

	s.	d.
6 and 8 oz., any shape, plain, or graduated ..	8	0 per gross.
3 and 4 oz., ditto ..	7	6 do.
1 oz. Moulded Phials ..	4	6 do.
1 oz. ditto ..	5	6 do.
1 1/2 oz. ditto ..	6	0 do.
2 oz. ditto ..	7	0 do.

No remittance required until the goods are received. Packages free. Delivered free within seven miles. Immediate attention to country orders. Post-office Orders payable to S. Isaacs and Son, at the Post-office, Tottenham-court-road, London. Bankers: Unity Bank.

**Great Reduction in the Prices of New**

MEDICAL GLASS BOTTLES and PHIALS, at the ISLINGTON GLASS BOTTLE WORKS, ISLINGTON-PLACE, PARK-ROAD.

Warehouse—2, UPPER COPENHAGEN-STREET, BARNESBURY-ROAD, ISLINGTON, LONDON, N.

E. and H. HARRIS beg to submit the following prices for quantities of not less than 6 gross, assorted to suit the convenience of the purchaser.

	8s.	per gross.
6 & 8 oz., any shape, plain or graduated ..	7s.	6d. do.
3 & 4 oz., do. ..	4s.	6d. do.
1 oz. white moulded phials ..	5s.	6d. do.
1 oz. do. ..	6s.	0d. do.
1 1/2 oz. do. ..	7s.	0d. do.

No remittance required until the goods are received. Packages free. Delivered free within 7 miles. Immediate attention to country orders. Post-office orders, made payable to E. and H. HARRIS, at the Chief Office, London.

Bankers: Union Bank of London.

**BROUGHAMS.**

**Kinder, M'Naught, and Smith,**

MANUFACTURERS, WORCESTER, beg respectfully to invite the attention of professional men to their improved Medical Broughams, as under:—

Width of Seat.	Weight.	Price.
3 ft. 5 in. ..	7 1/2 cwt. ..	83 Guineas.
3 ft. 6 in. ..	8 1/2 cwt. ..	95 Guineas.
3 ft. 7 in. ..	9 cwt. ..	100 Guineas.

The latter, including a segmental front, with seat for third person. These Carriages are constructed, by the aid of machinery, of the best material, are of excellent workmanship, and particularly adapted to the wants of medical men, either in town or country. Drawings and other particulars forwarded on application.

**Medicine Chests.**

MARSH & GRIFFITHS,

LATE

SPRINGWEILER,

2, DUKE-ST., SMITHFIELD, LONDON, E.C.

Chests from 3s. 6d. to £10. Ship Chest

according to Act of Parliament.

Established 60 years.

## ORIGINAL LECTURES.

## A COURSE OF CLINICAL LECTURES

ON

## DISEASES OF THE KIDNEY.

By GEORGE JOHNSON, M.D. F.R.C.P.

Physician to King's College Hospital.

## LECTURE V.

A case of fat kidney, which has ended in death, may fitly form the text of our lecture to-day: the case is reported by my clinical clerk, Mr. Wood. The subject of the disease was a boy, R. A., aged 14, who had been employed in a fishing-smack, and thereby much exposed to wet and cold. You will find that among the so-called working-classes exposure to cold and wet is one of the most frequent of the exciting causes of kidney disease. Add to this the intemperate indulgence in alcoholic liquors, and we account for at least three-fourths of the cases of Bright's disease among Hospital patients. There is no reason to suppose that this boy had been intemperate in the use of alcohol, but it is probable that frequent drenchings in an open boat, sometimes, as he says, of twenty-four hours' duration, had checked the functions of the skin, and thus induced the renal mischief. This is one of the cases, by no means uncommon, as you will learn in practice, in which it is impossible to determine with anything approaching to accuracy the date of commencement of the renal disease. With the exception of occasional soreness of the throat, which had troubled him during the last eighteen months, he had had no symptom of illness until about a month before his admission into the Hospital. There had been none of the symptoms which we always inquire for in cases of suspected Bright's disease: viz. increased frequency of micturition, an unusual increase or diminution of the quantity of urine, unnatural colour of the secretion, pain in the back, which by the bye is rarely complained of in cases of *chronic* Bright's disease, headache, bleeding at the nose; nor had there been any appearance of dropsy until about a month before he came under our observation, when the oedema began in the ankles, and quickly extended upwards to the thighs, the scrotum, and the face.

He was admitted on the 10th August, 1857. He had then the pallid look of a patient with renal disease. There was some oedema of the face, and considerable dropsical swelling of the lower extremities. The scrotum, too, was much swollen, and its skin inflamed, apparently in consequence of some punctures which had been made a few days before for the purpose of lessening the dropsical swelling. This leads me to remark that I have on more than one occasion seen severe inflammation and painful sloughing of the scrotum follow a puncture intended to reduce oedematous swelling of the part. Oedema of the scrotum, and of the foreskin, is a troublesome condition, from which the patient is often very anxious to be relieved. I advise you not to seek that relief by puncturing either the scrotum or the foreskin, but when other means have failed, if, as almost invariably happens, the legs as well as the private parts are dropsical, by puncturing one or both legs near the ankle, you may quickly reduce the swelling of the scrotum, and with much less risk of inflammation and sloughing than when a puncture is made in the scrotum itself.

Now to continue our patient's history. I find it noted that at the time of his admission he complained much of pain in the throat, the tonsils were swollen, the mucous membrane of the soft palate and fauces was red, and there was a superficial ulcer on the uvula. The skin was hot and dry, the pulse 120, and the respiration 48. There was no evidence of disease within the chest. The urine was high coloured but not smoky; it was acid; sp. gr. 1024, highly albuminous, and on microscopical examination it was found to contain numerous small waxy casts, a large proportion of which entangled oil, either in the form of scattered globules, or in cells, (see fig. 6.) No blood corpuscles were visible.

I have already remarked that we could not with certainty determine the date of the renal disease in this case. The dropsy had existed only a month, but you must bear in mind that in many cases of chronic Bright's disease the renal degeneration has been in progress long before the occurrence of

dropsy, and we were led to suspect that this had been so in the present instance, when we found the evidence, which I have just now mentioned, of fatty transformation taking place in the kidney. You are not to suppose that the appearance of a few oil-globules in the tube-casts is always an indication that the kidneys are in a state of chronic and incurable disease; for it will be found in a large proportion of cases of acute Bright's disease, that during the convalescence more or less oil is mixed with the epithelium or pus, or other inflammatory products which appear in the urine. The prognosis is much more unfavourable when, as in the case which we are now considering, many tube-casts contain oil *not* associated with renal epithelium, or pus, or blood;—appearances which indicate the existence of an acute inflammatory condition of the kidney. To this remark I would add that, according to my experience, the early appearance of large quantities of oil, even in cases of unquestionably acute Bright's disease, is a symptom of unfavourable import, which you will do well not to disregard.

Fig. 6.

Urinary sediment containing oil in casts and cells from the kidney; magnified 200 diameters.

I need not detain you long by detailing the treatment which we adopted in this case.

Obviously one great object was to support his strength by such mild nourishment as he could take, in the form of milk and beef-tea, without over stimulating and adding to the renal congestion by large doses of alcohol. At first we had him dry-cupped on the loins every night, afterwards he had the hot-air bath. During the first few days he took ten-grain doses of chlorate of potash every six hours, with the good result of healing the ulcer before mentioned on the uvula. We then gave the muriated tincture of iron in infusion of quassia three times a day. On one occasion, three days after his admission, we gave a purgative pill and draught, but a tendency to spontaneous diarrhoea, by no means uncommon in these cases, rendered it unnecessary and inexpedient to repeat the purgative dose.

We found that, in spite of all our efforts, the worst symptoms continued. He daily became weaker; the urine, always scanty, was often passed with the stools, and its quantity could not be accurately determined; it was still highly albuminous, being rendered nearly solid by heat or nitric acid, and it always contained the oily tube-casts. At length his face became sallow and shrunk, the tongue dry, the teeth covered with sordes—a state of mouth very like what is often seen in continued fever, and almost constantly found in those who are dying of Bright's disease with suppression of urine. Finally, he passed into a state of gradually increasing drowsiness, and died on the 13th September, little more than a month after his admission, and two months from the first appearance of dropsy.

On post-mortem examination the kidneys were the only organs which were found diseased. They were considerably enlarged, their combined weight being 16½ ounces. The cortical substance was pale, soft, and oedematous, its surface smooth, and scattered over with numerous small yellow specks, very like the atheromatous patches which are often seen on the inner surface of a diseased artery. These yellow-

specks are sometimes called the "true granulations of Bright." As they are almost entirely composed of oil, they are better designated "fat granulations," and the kidney which contains them a "granular fat kidney."

If you carefully examine these granulations with the microscope, you will find that each is composed of a convoluted tube, the contents of which—epithelial cells, mixed often with an albumino-fibrous exudation—have passed into a state of fatty transformation. In some, a considerable length of tube may be found entire with its fatty contents; but in other instances the tubes have been ruptured either during life or in the process of examination, and the oil, partly in the altered epithelial cells and partly in the form of free globules, is scattered over the field of the microscope. The proportion of the tubes affected by this degenerative change varies much in different cases. Sometimes it is difficult to find a tube in the cortical portion of the kidney which is entirely free from morbid change, while in other cases comparatively few tubes are affected. The naked-eye appearances of the kidney, the number and size of the fat granulations, afford a tolerably accurate measure of the extent to which the renal tissues are degenerated. It is evident, too, upon the most cursory examination of the kidney, that the disease is one which primarily and essentially affects the secreting portion of the organ; for while the cortical part is pale, anæmic, oedematous, and studded over with fat granulations, the medullary cones, which, as you know, are composed of straight tubes, having the office of ducts, and not of secreting tubes,—these medullary cones retain their normal colour and vascularity; and the straight tubes, except that they are sometimes filled with materials which have been arrested in their passage out from the convoluted tubes, undergo little structural change.

If you inquire into the general history of these cases of granular fat kidney, you will learn that, while there are some points of agreement between them, there are important differences, with which you will gradually acquire a practical familiarity by a careful study of individual cases. It may perhaps assist you in this inquiry, if I briefly allude to some of the main features of this form of disease.

You will find in a rather large proportion of cases that this form of Bright's disease, the "granular fat kidney," dates its origin from an attack of acute renal dropsy, the result of scarlatina, or less frequently of some other of the zymotic diseases, measles, or typhus, or erysipelas, or it may have resulted simply from exposure to wet and cold,—a frequent cause of acute renal dropsy, even without the concurrence of a morbid blood-poison. The patient, perhaps, recovers from the dropsy, but the urine does not cease to be albuminous; and if you have watched the secretion during the progress of the illness, you have found that the oil, which at first was associated with inflammatory products, continues after these have disappeared. The urine has now regained its natural sherry tint; its density and quantity are normal; after standing for a few hours it deposits a light cloud, which contains the oily casts and cells in variable numbers (see fig. 6), and it is albuminous, often, in a very high degree. The dropsy has disappeared, and the patient, being free from pain or other serious inconvenience, believes himself to be well. We know, however, that not only is he far from being well, but that henceforth he must be content to live by rule, and that the duration of his life will be very materially influenced by his ability and his willingness to observe such reasonable precautions as it will be our duty to suggest to him. For the poor man whose daily labour exposes him to cold and wet, the prospect is a very miserable one. We not uncommonly have cases of this kind in the Hospital; men who are tolerably well during warm and fine weather, when they can pursue their work in the open air without detriment, and even with benefit to their health, but who quickly become invalided and dropsical during the inclement season of winter. They are usually much benefited by a temporary stay in the Hospital, the dropsy soon passes off, and they return to their work, until renewed exposure excites a fresh attack of dropsy, and again brings them into our wards.

Those who, suffering from this form of chronic Bright's disease, have yet the comparative good fortune to be placed in circumstances which enable them to avoid the hardships and exposure which are incidental to a life of manual labour, may often live in the enjoyment of very tolerable health for a considerable number of years. My experience of the last few years has taught me that "the expectation of life" among this parti-

cular class of patients is considerably greater than I had formerly supposed it to be. The most favourable cases are those occurring in private practice, and in the middle and upper ranks of society; but one of the most remarkable instances which I have met with is that of a man named Stephen Gray, whom some of you will remember to have seen in the Hospital. The early history of this case is published in my book on "Diseases of the Kidney." He first came into the Hospital in October 1846, with acute general dropsy and albuminous urine. Before he left the Hospital there was distinct evidence that he had fat kidney. The dropsy disappeared, but the urine continued to be albuminous, and it always deposited tube-casts containing oil. I saw him occasionally for several months after he left the Hospital. His general health continued good, and he had no return of the dropsy, but the morbid characters of the urine remained unaltered. I then lost sight of him for several years, until October 1855, when he again came under my care here. He then told us that during the previous six years he had been serving as steward on board an Antwerp steamer, and had enjoyed excellent health until January of that year (1855), when he was suddenly seized with hemiplegia, from which he had but partially recovered, the left arm and leg being still very weak. Remembering his previous history, we were much interested in the condition of his urine. We found it still highly albuminous, and still depositing the oily tube-casts.

This patient finally came under my care in the Hospital and died in October 1856, exactly ten years from the time of his first admission with acute dropsy. The whole history of the case is very interesting, but my only object in thus briefly referring to it now is to give you an example of a patient who is known to have had symptoms of fat kidney for a period of ten years; and I may add that in all human probability he might have lived several years longer, but for the unfortunate habit which he had latterly acquired of drinking excessive quantities of whisky. One circumstance in this patient's history which had probably exerted a very favourable influence upon his health, is the fact that he had lived much at sea in his capacity as steward on board a steamer. The beneficial effects of sea-air, and especially of a prolonged sea voyage, are often very great and permanent.

Before I conclude, let me direct your attention to one feature in some cases of "granular fat kidney." I have told you that this form of disease sometimes commences with an attack of acute renal dropsy; let me now impress upon you the fact that in not a few cases the disease is latent and insidious in its origin and progress. There is reason to believe that it has sometimes existed for months, and even for years, before its presence has been suspected. The patient has at length, perhaps from exposure to cold, got symptoms of dropsy. The urine is then found to be albuminous, and the risk now is that an inveterate degeneration of the kidney may be mistaken for an acute and curable disease. In order that you may avoid this mistake, and the discredit which an erroneous prognosis is sure to bring upon you, let me remind you of the remarks which I made in the early part of this lecture on the appearance of large quantities of oil in the urine of patients who are labouring under a recent attack of general dropsy. The dropsy may be unquestionably recent, but the renal disease may have existed long before. I shall have more to say on this subject upon some future occasion, when I have an opportunity of bringing before you examples of other forms of chronic Bright's disease.

ACADÉMIE DE MÉDECINE DE PARIS.—At the meeting of this body, Feb. 2, M. Littré was elected free associate or honorary member by the votes of 63 out of 73 members present; and on the 9th the same honour was conferred on M. Isidore Geoffroy W. Hilaire by 62 out of 71 votes.

STATISTICS OF RABIES CANINA.—The *Veterinary Journal* of Lyons publishes the number of cases brought for treatment to the Veterinary Hospital. In 1856, 29 dogs died, and in 1857 the number rose to 49—the recent impost upon dogs not having as yet had the expected effect of checking the number of cases of rabies. There are 44 dogs, and only 5 bitches. As contradictory to the vulgar opinion that rabies is an especial disease of hot weather, it may be mentioned that 25 of the cases occurred during the winter, and 24 during the summer months.

## ORIGINAL COMMUNICATIONS.

## ARMY MEDICAL REPORTS.

(SELECTED, BY AUTHORITY OF THE DIRECTOR-GENERAL, FROM DOCUMENTS IN THE OFFICE OF THE ARMY MEDICAL DEPARTMENT.)

No. XXXIV.

ABSTRACT OF TWO CASES OF  
POPLITEAL ANEURISM SUCCESSFULLY  
TREATED BY COMPRESSION.

By ALFRED CROCKER, Esq.  
Surgeon, 2nd Battalion 1st Royals.

George Overton, private, 2nd battalion, the Royal Regiment, aged 30, twelve and a half years' service, a healthy-looking man, seldom in Hospital, was brought to the Regimental Hospital at Malta, on the night of April 10, 1857, complaining of pain in the right knee and calf of the leg, which was so severe that he was obliged to be relieved off sentry. On examination, a large oblong pulsating tumour was observed in the popliteal space, which was found to be an aneurism. The sac was about four inches long, and pulsated strongly, the pulsation being readily controlled by pressing on the femoral artery, and a loud bruit was heard on applying a stethoscope to the tumour. The man stated that he had felt something wrong with the leg for nine or ten days, which made him walk rather lame, but he had continued at his duty up to the time of admission.

It was determined to attempt the cure by compression, although from the large size of the sac the chances of a favourable result were considered rather doubtful.

On the 11th April Carte's instrument was applied over the femoral artery, about three inches below Poupart's ligament, and a sufficient degree of pressure used so as nearly to intercept the flow of blood through the sac, the part having been first shaved, and painted over with a strong solution of nitrate of silver to lessen the sensibility of the skin; the leg was enveloped in a flannel bandage, and digitalis given internally to reduce the force of the circulation. A second apparatus was applied over the pubes, so as to avoid maintaining pressure entirely on one spot, the one being tightened when the other was slackened.

At first he experienced great pain, and was unable to bear pressure in one place for more than about three hours at a time; but he soon became more tolerant, and could endure it for a much longer period. On the 15th there was slight vesication caused by the lower instrument; its position was, therefore, altered a little. By the 24th the sac had decreased a good deal, and was much harder, a large slough, however, had formed on the anterior part of thigh; the lower apparatus was therefore obliged to be removed, and the small pad of a tourniquet, fastened in a piece of cork, and over which was placed a four-pound weight, which was retained in position by an orderly, relieved every hour, substituted instead of it. By this means steady and efficient pressure was maintained without causing so much disturbance to the surrounding parts; a bladder of pounded ice was also placed under the ham, so as to keep constant cold to the sac. These measures were continued until the 4th May, when the treatment (with the exception of constantly keeping ice to the part) was obliged to be suspended on account of fresh and deep sloughs having formed, accompanied with great tenderness and inflammation of the surrounding skin. The sac at this time was reduced to half its original size, and was quite hard, but a distinct pulsation could still be felt in the tumour, and a faint bruit heard.

The slough having separated, and the limb being in a more healthy state, pressure was resumed on the 11th May by means of the pad and weight, held as before by an orderly, and the position of which was shifted occasionally to different parts of the vessel to prevent any further mischief from the pressure. On the 23rd of the month the Royals embarked for Gibraltar, and the patient was left behind under charge of Assistant-Surgeon Bleckley, 14th Regiment, who very carefully and assiduously watched the

further progress of the case, and pursued the same course of treatment. By the 16th of June pulsation had entirely ceased in the sac, but it was considered advisable to continue the pressure until the end of the month, when it was laid aside, and the cure was complete. The leg remained for some time weak, and the motion of the joint imperfect, but as the sac became absorbed, he gradually recovered perfect use of the limb.

The patient throughout displayed a degree of fortitude seldom surpassed, and which, no doubt, contributed in a great measure to the successful result. He rejoined his regiment at Gibraltar in the month of August, and has ever since been at his duty.

The second case is that of Private Edward Doran, aged 29, tall and of spare habit, with a sallow unhealthy complexion, though seldom in Hospital. Admitted on the 16th July last with dyspepsia, resulting from indulgence in spirituous liquors, and whilst under treatment he incidentally mentioned that he had a swelling in the back of right leg, which was rather painful. On examining the part I found that he had an aneurism of the popliteal artery, which he stated he first felt about three months previously. It was about the size of an egg, pulsated strongly, and on applying the stethoscope a loud bruit was heard. On compressing the femoral and manipulating the tumour, its size could be much reduced.

The same plan of treatment as recited in the first case was at once resorted to, but as we had only one *presse artère* (that of Carte), it was applied over the vessel at the lower part of Scarpa's angle, and a pad and weight, as already described, placed at a higher point of the vessel, and retained *in situ* by the hand of an orderly; thus a constant alternating pressure was kept up on different parts of the artery, and all sloughing avoided. It was not attempted to produce an entire cessation of circulation through the sac, but only a diminished flow of blood, so as to give time for the formation of clots, and the gradual filling-up of the tumour. The patient was extremely tolerant of the pressure employed, and submitted to the treatment with the greatest patience. On August 13 the tumour was much harder and smaller than on admission, and although no pulsation whatever could be felt, a faint bruit was still audible through the stethoscope. The pressure, however, had caused slight vesication, and it was considered advisable, therefore, to intermit it for a few days, after which it was re-applied as before. It was kept on altogether for the space of sixty-two days, by which time the sac was completely filled with fibrin, and the cure effected. The sac is now nearly obliterated, and the patient has been discharged from Hospital, is able to walk about well, and has the free use of the joint.

Although the time required in bringing the above cases to a successful termination was rather long, they are interesting, as showing that if compression be only steadily and perseveringly maintained, a favourable result may always be looked for. This was particularly exemplified in the first case, where the larger size of the aneurism, and the formation of extensive sloughs, presented a combination of unfavourable and embarrassing circumstances, which materially retarded the cure, but in the end were overcome by steadily persevering in the treatment.

APHORISMS AND OBSERVATIONS UPON  
CERTAIN DISEASES OF THE  
ORGANS OF SIGHT.

By W. R. WILDE, F.R.C.S.

Surgeon-Oculist to the Queen in Ireland; Surgeon to St. Mark's  
Ophthalmic Hospital, Dublin.

(Continued from Vol. XXXVI. page 651.)

**Fomentations.**—In no other class of diseases will fomentations, or, as we term them in Ireland, "Stupes," be found more beneficial than in affections of the eye. Simple warm water is perhaps as useful as any of the medicated applications; yet as such are esteemed by patients they should be prescribed. Laudanum and water, the aqueous extract of opium in decoction of poppies, or an infusion of chamomile flowers are always considered soothing. When we wish to keep the

pupils dilated an infusion of belladonna, applied either hot or cold, will be found very efficacious, as well as grateful to the patient. White wine vinegar and warm water is also, in some cases, particularly those of chronic ophthalmia or epiphora, very useful. As regards the degree of heat or cold employed in fomenting the eye, the feelings of the patient will be the best guide. In all cases where there is much discharge from the eye, either lachrymatory, mucous, or purulent, fomentations constantly applied are indispensably requisite. A small piece of fine flannel, or a bit of spongio-piline, forms a useful material for applying the fomentation, as they retain the heat a long time; or a fine sponge may be used instead—with the caution, however, that in certain cases it might propagate disease. Instances of such having occurred are too well known to require comment. A small fine uncut sponge—what is termed in the shops “a cup of sponge,”—is certainly a very comfortable mode of applying heat and moisture to the eye. In hospitals, barracks, schools, or public institutions, the general use of sponges in the treatment of diseases of the eyes is inadmissible; at St. Mark's Hospital we employ tow. In the purulent ophthalmia of infants great care should be taken by the mother or nurse in fomenting the eye, which is required to be done sometimes every hour. If the lids can be separated without pressure upon the globe, the fluid may be squeezed out of the bit of tow or lint, so as to fall on the eye and wash off the discharge. I think this much preferable to syringing, which is usually done with too much force. In this country the popular cure for ophthalmia neonatorum is breast-milk, the only use of which is that it serves to wash away the discharge. When, however, I reprimand mothers and nurses, as I have frequently occasion to do for using this remedy, it is not because of anything wrong or deleterious in the fluid itself, but because the faith in its efficacy often prevents the ignorant mother applying for medical advice until mischief is done, or in some cases the eye destroyed. I cannot help remarking here upon the notable fact that while midwifery practitioners call in the aid of either the general or special Surgeon, in most ophthalmic cases of severity occurring after the first year or two, they undertake without the slightest hesitation the treatment of the most virulent disease to which the human eye is subject, because it is in an infant or a child a few days old, and as such comes under the category of “Diseases of Women and Children.” There is no reason, however, why the accoucheur should not operate for cataract or stone if such were necessary in an infant, yet neither of these come within his special province. The fault is however more in the system than the man.

**Lotions**—are more frequently prescribed in ophthalmic than in any other range of diseases, and I think I might add more unadvisedly. Every apothecary's apprentice prescribes an eye lotion; every old woman recommends an eye water; general, Medical, and Surgical practitioners constantly prescribe collyria and washes for the eyes (the bases of which are either zinc, alum, or lead), for almost every description of ophthalmic disease,—cases of iritis, inflammation or ulceration of the cornea, pustular ophthalmia, injuries, even glaucoma, and often cataract, as well as for simple inflammations of the conjunctiva and the eyelids.

The objection is not so much to the lotion itself or its application, as to a remedy of this description being employed either in cases in which it is not applicable, or where the practitioner should have known that it cannot prove of the slightest benefit. Let the following instance illustrate this: Some years ago I was consulted by a lady of rank on account of partial amaurosis, which she had *accidentally* discovered a few days before. There were no symptoms to treat, with the exception of the misty vision which prevented her reading small print. I explained to her the character of the case, and as neither she nor I could tell *when* she had become blind, I did not order her any medicine, but desired her to watch the symptoms. She left the kingdom shortly afterwards, and I did not see her for two years, when she came to me to request I would order her a “lotion,” as she had forgotten her prescription in London. On making inquiry as to the progress of her case, she joyfully informed me that she was much improved, in fact “nearly well,” owing to the application of a vapour and a lotion which she had been applying every second day for some weeks past; on testing her sight, however, I found she was exactly in the same condition in which she had left me two years before; she was unable to read anything smaller than the letters on a sign-board.

In the olden times, when greater importance was attached to particular medicines, and particular formulæ than at present, great virtue was attributed to these “eye waters,” some of the formulæ for which will be found amusing to those fond of such inquiries. Those which have descended to the present time are the “aqua saffarina,” (a very nice preparation, by the way, made from the ammonuret of copper), the lotion made from the “*lapis divinus*,” the “aqua ophthalmica” of St. Yves, and the old extract of Saturn or Goulard, made from wine vinegar, and not as now with pyroligneous acid.

The secret “cure” possessed by some old ladies, and which people send great distances for, is generally what is known to them as “white copperas,” or sulphate of zinc. The whole arcanæ of ophthalmic cures, known and secret, has, however, received a severe blow from three causes, viz.:—First. Improved diagnosis;—an educated practitioner will not trust to a lotion for an “ophthalmia,” if he knows it is an inflammation of the internal structures of the eye, no more than he would for a pleurisy or an inflammation of the liver. Secondly. The more general use of common sense. And thirdly. Because the public are beginning to value an opinion without physic. I say beginning, because they have yet to be taught to pay for a good opinion without a Latin recipe; and the practitioner is often obliged, with a certain class of persons, to prescribe “something,” in order to secure his fee.

One of the best lotions I know of, in cases of accident or after operation, is cold water, iced, if more agreeable to the patient's feelings; but, to be effective, it must be applied with a single layer, or two folds at most, of fine old linen or cambric, so that evaporation may proceed with facility, and such cloths should be removed whenever they begin to become hot or dry, which will much depend upon the heat of the parts upon which they are applied, and the temperature of the surrounding atmosphere. In such cases the difficulty consists in having the directions carefully followed up; for, on coming to visit the patient, we constantly find a quarter of a pound of lint or a folded pocket-handkerchief, steaming hot, placed upon the affected organ. This need not be wondered at, when a recent work on ophthalmic medicine recommends the application to be made by “means of compresses!” Another mode of applying the fluid, formerly much in use, was the eye-glass, and it is still recommended by some Physicians. Although this was anything but a pleasant, and very often proved to be an injurious remedy, from the pressure it exercised on the inflamed globe, and the irritation which the stimulating fluid produced when coming in contact with so large a surface of the conjunctiva, yet it fulfilled the intention of the practitioner; for the eyelids being opened while the glass was inverted over them, and the head thrown back, the fluid absolutely came in contact with the conjunctiva and cornea, whereas now the lotion only touches the skin of the eyelids. Most vegetable and mineral astringents, as well as sedatives and narcotics, are employed by the ophthalmic prescriber, in collyria or eye-washes; for example, the preparations of opium, prussic acid, laurel-water, zinc, alum, lead, copper, and tannin; Mindererus' spirit, infusions of hops, green tea, or other vegetable astringents, and rose, elder, or orange-flower water are the general vehicles employed. One of the injurious consequences of eye-washes, and one that has, notwithstanding all which has been written upon the subject, been but little attended to, is, that certain salts, particularly those of lead and alum, deposit themselves on the cornea, not merely in the pit of the ulcer, but where there is the slightest abrasion of its conjunctival surface. Spirit and water is also a useful application; but neither dropped into the eye nor used as a lotion have I seen much benefit derived from a solution of bichloride of mercury.

The various holy-wells in Ireland, to many of which pilgrimages were made from great distances,—especially on their patron saint's days,—in former years were all more or less celebrated for the cure of sore eyes. Indeed, whatever good they did beyond that effected by the faith in their virtues was in ophthalmic cases. Take, for instance, a case of strumous ophthalmia in a young, or chronic ophthalmia in an old person, who travels thirty or forty miles on foot, buoyed up by accounts of cures, said to have been effected at these popular watering-places; and arriving there imbued with the most implicit faith in their efficacy, bathing the eyes continually with the cold clear spring, need we wonder at improvement following this most useful application together

with change of air and hope? Are not cures of other diseases among the upper classes effected through similar agency although with more parade? but the poor Irish are sneered at, because their water cure is denominated "superstition."

I have not found chloroform either in lotion or vapours effective in cases of photophobia; but latterly this symptom of disease has among all ranks of society lessened very much.

*Douches.*—The practice of immersing the face and then opening the eyes in cold water is in such general use that it scarcely requires to be alluded to; but in addition thereto I find benefit derived in many cases from throwing up cold water from the basin with the hand, and thus giving the eyes a sort of shower-bath.

In my Ophthalmic Report for 1846, published in the *Dublin Quarterly Journal*, I described and figured an apparatus for applying douches of hot or cold water, particularly applicable in Hospital practice. It consisted of a cistern fixed against a wall, with a tube brought down over a basin, and bent like a syphon at the end, to which a number of roses, like those of watering-pots, could be attached; a stop-cock commanded the power of the jet. Subsequent to my publication, portable "eye-fountains," of different shapes and colours, were sold by instrument-makers.

*Positives*—to the eye are still in very general and popular use, and were formerly considered applicable to all Eye diseases. They are most indiscriminately recommended;—for example:—A child meets with an injury of the eye; a heavy bread-and-water positive rolled up in a cloth is almost immediately applied, and when the Medical attendant comes to see it next morning, he finds the quarter pound of bread has become dry and hard, and the cloth in which it is contained is adherent to the brow and lids. Now all the good, in this case might have been effected by a fold or two of linen covered over with oiled silk or thin gutta percha, to prevent evaporation. Generally speaking, poultices of any kind are inapplicable, from their weight, in the treatment of eye diseases; moreover, they become quite dry between night and morning. Except in cases where the globe is suppurating, or in destructive injuries, especially with chemical substances, I seldom recommend them.

(To be continued.)

## ON THE ACTION OF PANCREATIC JUICE ON FAT.

By ARTHUR LEARED, M.B. L.R.C.P. M.R.I.A. &c.

Physician to the Great Northern Hospital, and Lecturer on Materia Medica at the Grosvenor-place School of Medicine.

I published some years since an account of a case in which singular microscopic bodies were contained in the fluids habitually vomited. I ascertained that these bodies were composed of fatty elements. The presence of pancreatic juice in the fluids as a result of obstruction in the duodenum was inferred. I proved by experiment with pancreatic juice elsewhere obtained that it possessed the remarkable property of forming similar bodies by its action on fat. Conversely it was thus inferred that this secretion had really been regurgitated into the stomach of my patient. Circumstances prevented my then investigating the subject further.

In M. Bernard's "*Mémoire sur le Pancréas et sur le Rôle du Suc Pancréatique dans les Phénomènes digestives, particulièrement dans la Digestion des Matières grasses neutres*," Paris, 1856—I find the following paragraph, page 68:—

"Je dois encore signaler ici une autre particularité intéressante qui survient dans le suc pancréatique normal qui s'élève spontanément; je veux parler de la formation spontanée de cristaux particuliers que j'ai signalés pour la première fois dans le suc pancréatique du chien, en 1848. Ces cristaux vus au microscope, forment des houppes soyeuses magnifiques, et m'en rapportant alors uniquement à la forme, je les avais pris pour des cristaux de stéarine ou de margarine, parce que je les avais vus se former quelquefois très rapidement dans des émulsions de graisses que j'avais produites avec du suc pancréatique. Depuis que j'ai parlé de ces cristaux, beaucoup d'autres observateurs les ont vus. Ils ont été représentés par M.M. Robin et Verdeil dans leur bel atlas de chimie anatomique, et ces auteurs regardent ces cristaux comme formés de sulfate de chaux. J'y ai bien trouvé la chaux, mais l'acide paraîtrait être un acide organique."

It may be supposed from this that M. C. Bernard may pos-

sibly have seen my observations. But if he had seen them it would also appear that he concluded them to be erroneous. I believe I have met with the crystals described by him and figured by M.M. Robin and Verdeil as those of sulphate of lime, and I affirm that they are not identical with the bodies I have figured and described. I own to some surprise, therefore, that the existence of the latter kind should be ignored by so eminent an experimentalist as M. Bernard.

A glance at the figures of M.M. Robin and Verdeil, (a) and at the wood-cuts given by myself, (b) will convince any one that the things represented are essentially different. I am aware it may be objected that the pancreatic juice or infusion used in my experiments was abnormal, having been obtained some time after death occurring by disease. I reply, that fluid so obtained possesses properties sufficiently curious to merit attention.

The correctness of my statements may be tested as follows:—Take a pancreas from the human subject as soon after death as possible; let it be cut into pieces and pounded in a glass mortar, with about 3ss. of distilled water at 98 degrees Fah. Having allowed it to stand a few hours, let the pancreatic tissue be well squeezed in a piece of linen; let a couple of drachms of the expressed fluid be put into a test-tube, with a few grains of mutton fat in a divided state. Place the test-tube in a water-bath, just warm enough to melt the fat, and when melted let the contents of the tube be well shaken up. Replace the tube in the water-bath, and allow it to cool gradually. An abundance of the bodies I have described may soon be discovered by the microscope in the fluid from the upper part of the tube. They are not, however, in every instance developed in the same degree. Out of two experiments I performed very recently, in one the echinus-like bodies were perfectly developed, in the other they were neither so numerous nor so perfect, but still present. Not only is decomposition of the fluid unnecessary for their production, but they disappear when decomposition occurs. There is a marked difference in this respect between the crystals of M. Bernard and these bodies.

That they are derived from fat by a peculiar action of the pancreatic fluid, I offer the following proofs:—

They are not found in this fluid without the addition of fat; their microscopic characters; their melting at a moderate temperature; their complete solubility in boiling ether; and lastly, from the frequent appearance of oil (oleine?), attached to the bodies that had evidently issued from their interiors. In some the spinous envelopes were even seen to be collapsed. In these instances it was evident that the crystalline portions of the fat had originally encased the non-crystalline.

I suggested in my former paper that the chief action of pancreatic fluid in the digestion of fat may consist in the separation of it into its proximate elements. This, as well as that margarine and stearine were not assimilated, occurred to me from reasons detailed. These views were strengthened by experiments I subsequently made on the effects of oleine obtained from cod-liver oil on patients, as compared with those of the residuary margarine. (c) Since then the same views have been advocated, chiefly as the result of experiments identical with mine, but without allusion to them. (d) I do not speak confidently on a part of my subject only. To this subject I shall return in a future paper.

It is well known that the essential action of pancreatic juice in the digestion of fat is held by M. C. Bernard to be that it forms an emulsion with the latter. He believes that in the minute subdivision of the fat thus effected, absorption of the whole occurs. Another action discovered by him is, that this emulsion, which is at first alkaline, soon becomes acid. This appears to me of especial import. It argues that decomposition occurs simply a step farther than I suggested. The acid reaction is due to the liberation of the acid principles of the fat, and this goes to prove that the essential action of the pancreatic fluid consists in decomposition. There is reason to believe, too, that the degree of decomposition has relation to the time of contact between that fluid and the fat. within the province of the professed chemical physiologist. It is the prerogative of the Physician to study physiology by aids more within his range. I have availed myself of a hint

(a) Op. cit. plate 6.

(c) Medical Times and Gazette, July 21, 1855.

(d) Dr. Garrod in British and Foreign Medical and Chirurgical Review.

derived from pathology, and I submit that, having acted on that hint, the evidence derived from therapeutics tends materially to strengthen my views.

48, Finsbury-square.

## CLINICAL EXPERIENCE ON THE NATURE AND TREATMENT OF UTERINE DEVIATIONS,

MORE ESPECIALLY OF PROLAPSUS.

By HENRY SAVAGE, M.D. Lond.  
Senior Physician to the Samaritan Hospital.

(Concluded from page 188.)

**Case 2.**—A woman; age 45. Complete prolapsus of uterus, bladder not included, as ascertained by the catheter. Vaginal ring strong but dilated; membranous perineum never lacerated. Could herself reduce the prolapsus easily on lying down; various pessaries previously tried, and laid aside on account of the pain and discharge they invariably produced sooner or later: attributed the prolapse to a strain on attempting to lift a tub of water about ten years ago, when she felt something give way, noticed something protruding about six months afterwards. This soon showed itself as a complete prolapsus. Married twenty years since. Two children. Nothing difficult in her confinements. Gets her living by washing and "chairing." Constant pain in the loins. Wretched feeling of bearing down. Looks worn and haggard as from long suffering.—Admitted.

Operation according to Plan 9. Chloroform gave her great distress, and was withdrawn by her earnest desire. Quills removed on fifth day, and the sutures on the sixth. Adhesion perfect throughout: not more than four grains of opium given from first to last, as it disagreed like the chloroform. At the end of a month, when allowed to get up, the new perineum was firm and sound. The uterus high up in the pelvis, just within reach of the finger. Appearance of the patient much improved. Pain in the loins gone. A week after getting about, the uterus could be felt much lower; after another week's rest in bed it had again ascended where it was when she was first allowed to leave her bed. For a second time she was allowed to walk about. The uterus again began slowly to descend. In another fortnight it was found resting on the new perineum, the os presenting at the new vaginal aperture. This was the state of things on her dismissal three months after the operation. An abdominal belt and perineal air-pad rendered her perfectly comfortable. It was ascertained that she could perform some of the more laborious duties of a servant in the Hospital without the least relapse, for a fortnight before she left.

Diet and dressings about the same as in the first case. A vaginal injection of nitrate of silver (gr. ii. to 3i.) stopped an obstinate purulent discharge attributed to an unhealed portion of the wound within the vagina.

**Case 3.**—A woman, 33; single; in very good health, looking strong, active, and capable. She said her sole complaint was "falling down of the womb," the cause of which she had no notion of. Had occasionally lifted heavy things, but never felt any inconvenience afterwards. Noticed something protruding about six years before; consulted a Surgeon, who told her it was the womb. On examination the womb was found entirely prolapsed; the vaginal ring strong, resisting, not dilated; membranous perineum perfect. The uterus, preternaturally small, had made its way out of a vaginal aperture already as contracted as could with propriety be left by any style of operation. The vulva altogether was exactly as is seen in young females of good moral character not suffering from prolapsus.—Admitted.

I thought this case might be benefitted by a kind of globular pessary, extremely light, which I had been using with much success during the past two years in cases of uterine displacements associated with a sound perineum. Dr. Meigs strongly recommends a globular pessary for the sake of lightness, made of beaten silver. I found the same advantage could be obtained by gutta-percha or india-rubber vulcanised; various sizes of this kind of pessary were tried, the patient being provided with a belt, and under air-pad. All did very well so long as she kept her bed, but immediately she

began to walk, or even stand, the womb commenced to descend; and, in spite of the under-pad, within a few hours out it came, of course forcing the pessary before it. Instead of this belt and air-pad, a similar belt with an under strap, the posterior half being a steel-spring, supporting a pear-shaped pad, playing on a piece of spiral spring wire, was tried. This is an apparatus which keeps its place; the pad never moves from the perineum, where it exercises an equable pressure, according to the adjustment when first applied. It is the best artificial perineal support known, and can sometimes be worn for months together without inconvenience. The patient could not bear the pressure for more than a day at a time, and was obliged to lay it aside. Dr. Zwankke of Hamburg had just sent me a dozen of his pessaries of various sizes. I selected the smallest. It succeeded perfectly. As long as it could be tolerated in the vagina there was not the least sign of the recurrence of the prolapse. About every fourth or fifth day, it was found desirable not to use it. Rest, and a few warm injections of diluted lead lotion speedily removed all vaginal irritation and discharge. Zwankke's pessary is intended to be removed once or twice in the twenty-four hours; this was done, and the vagina carefully syringed with warm water; and notwithstanding the interruption of a day about once a week, the patient, compared with her former state, might be said to be tolerably well relieved; however, having heard of case No. 2 she entreated to have "the same thing done to her."

The perineum and vagina being already quite natural, I hesitated about proceeding to obtain the main object of perineal operations, viz. the contraction of the vagina, and diminution of its aperture; eventually it was decided to operate as in the style of No. 9, Geddings. The quills were removed on the fifth day, the sutures on the sixth. Adhesion perfect. Not more than three grains of opium given. Nourishment moderate; wine found to disagree. She got up at the end of the third week. The womb could then be felt high up in its natural situation. It had descended a little at the end of the fourth week. The operation being considered successful the patient did not come under my particular notice till three weeks afterwards, when the nurse announced that the womb was presenting, and she thought would escape from the vagina every moment. So I found it; in fact, the next day there was the prolapsus, not perhaps quite so evident as at first, because, small as the uterus was, it was caught by the new vaginal aperture, but very shortly afterwards the uterus prolapsed as before the operation.

It should be mentioned that the belt and perineal pad was worn from first to last. I shall have again to advert to this case.

**Case 4.**—A woman, 45, married 25 years, six children, youngest ten years old. Prolapse complete shortly after her last confinement. Womb began to come down five years before; says she felt it as if ready to protrude. Judging by her account, the complete prolapse occurred rather suddenly, on attempting to lift a weight from the ground. Gets her living at the wash-tub. Various pessaries from time to time had been tried; they all failed. For the last four years the womb had never been reduced; she got about as she could, with a napkin to protect it. Remembers no particular difficulty in any of her confinements.

The prolapsed vaginal pouch contained the bladder, as indicated by the catheter, and some of the floating abdominal viscera. The size was enormous. Three large ulcers near the os uteri. Mucous membrane—covered with large flakes—had become dry, coriaceous, inelastic, hanging like a leather bag from the vulva. Vaginal ring imperceptible, being, with the larger labia and membranous perineum, distended and drawn out into a sort of thin open funnel.—Admitted.

The second of the foregoing three cases not having turned out entirely to my satisfaction, I determined to vary the style of the operation, after the manner indicated by fig. 11.

The prolapsus being reduced, and carefully retained, the whole of the loose tegument which could be fairly laid hold of was comprised in the external incision. The flap was dissected inwards towards the vagina, as far as a line previously marked off with the scalpel on the vaginal mucous membrane. Thus not only was all useless tegument removed, but the entire thickness of the vagina included in the vaginal line of incision. Two small arteries required the ligature. Care was taken to pass the armed needle through at the marginal limit of the vaginal incision, entering it at the skin far enough

from the wound to insure complete apposition throughout its entire surface. Quills were used in the usual manner; all hæmorrhage ceased the moment the suture was drawn tight; a few interrupted sutures completed the operation. Chloroform was given. The operation took less time than the former cases. The quills were removed on the sixth day; the adhesion appeared complete; the sutures were removed at the same time. A grain of opium was given three or four times in the twenty-four hours for the first few days, when nourishment, which she could not comfortably take before, was freely administered. The only dressings were cold or warm wet rags to the wound; frequent syringing of the vagina with tepid water. The legs were kept tied together at the knees, as in the former cases,—in this instance till the eighth day. She was allowed to get up at the end of the third week. The uterus was then high up in the pelvis; a couple of large vaginal folds could be felt within an inch of the vaginal aperture. At the end of the fifth week the womb had descended, when only the vaginal folds could be felt previously, these latter having greatly diminished. She left the Hospital on the ninth week after the operation, the womb resting on the new perinæum, which was firm, strong, thick, and resisting.

Six months afterwards this case presented herself at the Hospital. She had resumed her occupation about four months previously, which, she said, now caused her no inconvenience. On examination, the womb seemed to have slightly ascended, so as, although perhaps touching the new perinæum, not to rest upon it. Her general health had improved in the most remarkable manner. She said she felt equal to any exertion; in fact, she had for the last four months been supporting her family at the ironing board; the linear cicatrix was scarcely perceptible, (Cut 14,) the general appearance of the perinæum resembling that of a person of her age who had never suffered from prolapsus.

*Case 5.*—Case 2 having accidentally met the last case at the Hospital, very soon evinced much discontent at her own condition, and applied to be “done all over again.” Having examined her with my colleagues, who considered the result in her case quite satisfactory, I at first refused her request. At last I yielded, and, with the concurrence of the gentlemen above alluded to, proceeded to re-do her perinæum as in the last case. The old cicatrix was divided to the whole extent of the original wound by a bistoury, guided on the finger introduced into the vagina. The external incision now included as much integument as it was thought could be spared. A piece of vagina was cut away, as in the last case. The wound bled rather freely until the quills were drawn together, when the bleeding ceased at once. No chloroform was administered. Opium in grain doses disagreed, and was discontinued. The quills were removed on the fifth day, sutures on the sixth, when all seemed going on as well as usual. In a few days the wound opposite the middle thread looked inclined to slough; in a few days more the slough came away, leaving rather a large opening. Adhesion elsewhere very satisfactory. Wine and nourishment was pressed upon the patient. She took it at first with much disinclination; she soon, however, regained her relish for it, and then the appearance of the wound began to improve. A lotion of chlorate of potash, 3j. to a pint, appeared particularly efficacious in giving the opening a healthy aspect. It speedily healed by granulation.

At the end of a month the patient was allowed to get about. The womb was now high up in the pelvis. In another fortnight it had descended nearly down to the new perinæum. A belt and under air-pad made her feel secure; but it did not in any way contribute to the support of the womb, which descended no further to the present time, now six months after the second operation. For the last four months this woman has assisted in all the heavy domestic work of the Hospital.

*Case 6.*—A woman, 38, married 20 years, 4 children, youngest 6 years old, complete prolapsus for the last five years. Bladder not included. Was in the habit of retaining the uterus *in situ* by means of a piece of sponge. No other form of pessary could be endured. The inverted vagina, therefore, was tolerably healthy. The womb was large, but not unhealthy. She had heard of the operation, and being tired of the sponge, notwithstanding it was tolerably effectual, and gave her no pain, she applied at the Samaritan Hospital. Vaginal ring dilated, but strong and resisting. Membranous perinæum, untorn, but loose and redundant.—Admitted.

The operation was performed according to fig. 11.

Chloroform was administered. Not more than six grains of opium, in grain doses, was given during the first two days; on the third day it was discontinued. The quills were removed on the fifth day; the interrupted sutures on the 6th. Adhesion firm and complete throughout. The patient allowed to get up at the end of the third week. The uterus, which till then had retained its natural situation in the pelvis, immediately began to descend. It soon was found resting on the new perinæum, within an inch of the vaginal aperture. At the end of the sixth week she was allowed to go home. A careful examination the day previous showed that the uterus had slightly ascended.

Three months afterwards this patient came again to the Hospital. In the interim she had got through all her domestic duties, without the least sign of prolapsus, notwithstanding her having laid aside her band and perineal pad a week after her return home. The uterus seemed exactly where it was on her dismissal from the Hospital. As the vagina had all along continued particularly healthy, I thought I would try a course of Zwanke's pessaries, accordingly, after three or four trials, a size was found which she could wear without pain. This patient came again six months afterwards, having laid aside her pessary for a month. The uterus had ascended considerably; she was told not to use the pessary again without applying first to the Hospital. She has not made her appearance since.

*Case 7.*—This patient (Case 3), notwithstanding it had been fully explained to her, that no operation short of entirely closing the vaginal orifice, perhaps not even that, would be likely to succeed in her case, returned to the Hospital to request to be “done all over again.” Since she left she had been wearing a Zwanke's pessary, which, as it always does, kept the uterus well up in the pelvis. She had neglected both, to remove it once or twice a-day, and the free use of the vaginal douche, which is generally sufficient to render this invaluable instrument most effectual. The vagina was tender, but showed no other indication of injury from the pessary. One effect of the operation, according to Plan 11, besides diminishing the vaginal aperture and advancing forwards a firm, solid, resisting perinæum, is a narrowing of the inferior part of the vagina, so that by adopting it in her case I was not without hope of comparative success. She was accordingly admitted, and the operation performed as above. The sutures were removed, and the same course of after-treatment pursued as before. The union was complete throughout. She was allowed to get up at the end of the third week. She remained in the Hospital two months, carefully watched. The uterus began to descend as she moved about, entirely resting on the new perinæum, from which it ascended slightly just before she left the Hospital. The case was looked upon as successful. She was provided with a belt and under-pad, and returned home into the country.

Eight months afterwards she returned to the Hospital, with her uterus projecting half out of the vaginal aperture, from which, small as it was, the still smaller and rigid orifice prevented its entire escape. She continued to attend regularly as an out-patient. The uterus was easily reduced, and retained by a small-sized Zwanke, now introduced not without difficulty. One day, having left off the Zwanke, the prolapsus became complete, and it could then be seen how the vagina solely could be inverted like the finger of a glove, and how the superincumbent pressure with the mechanical advantage presented by the inverted sac had overcome the very considerable resistance presented by the constricted vaginal aperture. The vagina covering the body of the uterus was marked by a circular furrow where it had so long been caught in the vaginal orifice, the os being dark and turgid in a degree indicating a positive strangulation.

*Case 7.*—A woman, aged 41, single, nervous, rather hysterical, otherwise healthy. For the last six years had complete prolapsus uteri, which she could at once reduce on lying down, when it sometimes became reduced spontaneously. The uterus occasionally would remain in its place for days together, but generally she could feel it descending immediately she began walking about, when it soon forced itself entirely out of the vulva, notwithstanding the various pessaries, belts and bandages she had been advised to have recourse to. The vaginal ring was firm, resisting; no loose tegument about the membranous perinæum; vaginal aperture dilated, and perinæum carried back by the long standing pressure of the prolapsed uterus, which, with the mucous

membrane (vagina) was quite healthy. The vagina alone was inverted, the prolapsus contained the uterus only. The case closely resembled the last, the only difference being that the uterus was rather larger, and the perineum, although strong and unyielding, was too far back to offer all its usual under support. Altogether the points of resemblance were strongly suggestive of similar disappointment, and I persuaded the patient to try such pessaries, bandages, etc., as had been found with us most serviceable in similar cases. No form of perineal support could be worn, and every kind of pessary but a Zwanke was forced out with the uterus a few hours after their introduction. This woman was taken at once into the Hospital, so I had an excellent opportunity of watching the extraordinary and to me unexpected extrusive force called into play the moment the patient made the least effort in the upright position whenever the uterus descended so low as the vaginal orifice, or far enough to be the lowest part of the inverted vagina. Of the two forms of pessary, viz. the stem and Zwanke (all others would have been useless) the former the patient could not wear, the latter she declared herself unable to bear for more than half a day at a time. It came at last to a consultation as to the advisability of resorting to the operation.

The vaginal ring was dilated, the perineum having been pushed back by the prolapsus. The uterus was longer than in the former case. By bringing the perineum forward the vaginal angle would be reproduced. This, together with the contraction from the operation, it was expected would offer a sufficient obstacle to the escape of a uterus larger than the other analogous case. The operation was very carefully performed according to Plan 11. Adhesion by first intention took place throughout. The patient got about at the end of the third week, when the uterus began to descend as usual; it soon was found resting on the new perineum. A belt and under-pad was applied. She went on well for another three weeks, when she began to complain of "bearing down," and some other symptoms she remembered as precursors of the original prolapsus. The os uteri was found presenting at the vaginal orifice. Rest, astringent injections, and tonics, answered so long as she made no exertion, but this speedily brought the uterus again down, so as to present as before. She was kept some time longer in the Hospital. Eventually she was allowed to go into the country, with all proper injunctions as regards wearing the belt and under-pad, and avoiding, as much as possible, any effort tending to renew the evil.

This patient returned four months afterwards, with the uterus again entirely prolapsed. The contraction of the wound had not, as anticipated, closed the vagina sufficiently to prevent the organ from slowly squeezing its way out, which it had succeeded in doing, in spite of the under-pad and every precaution. The uterus is now very well kept in its place by a Zwanke, which she bears much better than formerly.

Case 8.—This was a private patient, the wife of a farmer, one hundred miles from town. Age, 65; six children; youngest 28. Was accustomed, until the prolapsus got so bad as to prevent her, to superintend the domestic business of the farm. Cannot remember she was ever ill; her confinements all natural. Thinks it probable she "strained herself in lifting a milk-pan;" is not sure, her circumstances not requiring her to undertake any laborious duty. About six years ago felt something unusual pressing on the perineum; was told it was a falling down of the womb, and recommended to avoid exertion, and rest in the inclined position as much as possible. The womb soon prolapsed entirely notwithstanding. For the last five years had tried various kinds of supports and pessaries, which she lately laid aside, quite worn out by them, and was told there was nothing left but to keep her bed.

The uterus was above the full size, rather hard, but healthy; the vaginal membrane less altered than usual. The vaginal ring was greatly dilated, and carried back, offering no impediment whatever to the prolapsus. The bladder was included. The prolapsed mass about the size of a small foetal head.

She was placed in lodgings in the neighbourhood; the most unobtrusive form of stem pessary she could not manage, and a Zwanke, selected after repeated trials, came away in the street, so I persuaded her to submit to the operation.

The operation was performed according to Plan 11. Chloroform was given. Opium caused much sickness and distress, and was discontinued the second day; also tonic and every

form of stimulant, for the same reason. The sutures and quills were removed on the fifth day; the knees were kept bound together till the 10th; adhesion complete throughout. She got about at the end of the third week. A belt and pad was provided. She called upon me the sixth week after the operation. The uterus was low down, but not resting on the new perineum. Matters were thus when she left town on the tenth week.

It is twelve months since I operated in this case. The patient has just written to say she has long been able to attend to the affairs of the farm as well as ever. She ceased wearing the belt and pad six months ago, to her great comfort and satisfaction. In short, she had seen nothing of the prolapsus since the day of the operation, and felt no symptoms whatever of its probable recurrence.

The above cases are, as I said before, selected from twenty-two cases of prolapsus uteri treated by operation. I have been desirous to give just so much detail and no more as would justify the observations premised, and illustrate subsequent treatment. The remarks on the use of the pessary are founded on the experience of the last eight years at the Samaritan Hospital, where a large proportion of uterine cases are always under treatment. There is a strong prejudice existing still in most quarters against any surgical proceeding for the cure of prolapsus. In this respect I may mention the recorded opinions of that very high authority on such matters, Dr. West; but I am not without hope of persuading even him that henceforward a case going on for fifteen years unrelieved, like Case 1, would be a disgrace to surgery. As I said above, Fricke's operation, as performed by Fricke, must fail eventually. I imagine Dr. West's experience extends no further, and I do not hesitate to appeal to Case 8 as the most satisfactory test of the certainty of Fricke's plan modified in some such way as there adopted. The proximate cause of prolapsus and the more remote circumstance leading to it would of course be self-evident the moment it could be decided what were the true anatomical conditions tending to keep the uterus from falling. On this point I can confidently refer to what I have said about the cervical ligaments.

Assuming Fig. 3 to be a fair representation, as I believe it is, of the natural average relations of the uterus, it is evident that no pessary but Simpson's could completely answer. All other pessaries push that organ out of the vagina *somewhere* into the pelvis, and the comfort so frequently following their introduction when not too large and well selected, is due to their maintaining it at a certain elevation, doing away with that dragging on a part of the peritoneal lining of the pelvis, which can seldom bear it without giving more or less distress. One of the best German authorities, Professor Scanzoni, who represents the school of Vienna, in his recent work, lays it down as an axiom, that no form of uterine displacement causes suffering if the uterus be not diseased. A judicious selection of a pessary will at any time decide the question greatly against the inviolability of this axiom. A round pessary, not more than two inches, nor less than an inch and a-half in diameter; a set of Zwanke; a stem sponge pessary with perineal support, are resources which should be early and well tried in every appropriate case. A free use of the vaginal douche is generally most effective in keeping down irritation. This, or some form of operation as described, I should certainly rely on to the full extent indicated in this paper.

The two cases of failure by operation illustrate two to me unexpected contingencies:—1st. The possibility of a simple inversion of the vagina. 2. The smallness of the uterus as a cause of failure in Fricke's operation. Until I met with them I shared in the general belief, that the chance of failure was proportionate to the size and weight of that organ.

## ON SOME CASES OF MALFORMATION.

By ROBERT GARNER, Esq. F.L.S.

Surgeon to the North Staffordshire Infirmary.

THE following observations on certain malformations may be considered worth insertion in the *Medical Times and Gazette*, particularly as several of the cases will be in juxtaposition there with two or three others already reported. The first defect is not a very uncommon one, since the writer knows of another living individual affected with the same unfortunate

conformation. Individual cases, however, have peculiarities worth recording, as in the following instance:—

A. B., about 30 years of age, a strong and healthy man, applied to the writer with the following curious genito-urinary malformation. At the lower part of the abdomen appeared a fleshy-looking protrusion, evidently the posterior portion of the bladder, with its internal lining membrane. Towards the inferior part of this body might be seen two minute openings or slits—the orifices of the ureters—from which the urine generally came away *gustatim*, but occasionally also in minute jets. This surface was constantly moist with mucus, which might also be squeezed out in yellow opaque drops from many crypts or cells. The *osса pubes* were deficient, as were the recti muscles, neither was there any umbilicus in this case, though one exists in the other individual above alluded to. There was a smaller, half-separated tumour on the right side of the principal one, about the size of a walnut, probably originally the root of the funis, or, perhaps, of the umbilical vesicle; and as some idea was at first entertained of improving the parts by a sort of Taliacotian operation, this was tied, and shortly cut off by the man himself with impunity, on account of the pain which the ligature caused him. Below the protruded part existed a very short penis and glans, with a prepuce, but entirely split dorsally, the broad groove being covered with mucous membrane, and having at the bottom, apparently, the seminal orifices. Over this surface the urine was constantly dripping. Small testicles existed below the penis, with spermatic cords, but a scrotum could scarcely be said to exist, though its raphe was visible; this part and the groins were covered with hair, and the patient had occasional seminal evacuations. The uniformity presented in such cases shows that their occurrence is deducible from the existence of certain laws of formation, the embryonic duplicity of parts, rather than the existence of the uro-genital sinus; the higher situation showing this. The above state of things had not prevented the poor fellow leading a useful, and apparently contented life, residing on one of the wide moors of North Staffordshire, and thriving as a nail-maker. It seemed unlikely that anything could be done to cover over the tumour, partly on account of an inguinal hernia on each side, and the deficiency or weakness of the parietes of the abdomen. A *gutta-percha* shield was fitted to the part, and a better plan to catch the urine contrived. An india-rubber bottle and stop-cock, as suggested by one of your correspondents, appears to be the best contrivance for such cases.

Experiments with hydriodate of potash, rhubarb, and ferruginous of potash, were tried on this patient, and once or twice appeared to be detected in the urine (after being administered in a solution by the mouth) in less than four minutes; but generally not till eleven or twelve had elapsed. A prolonged fasting appears necessary to ensure the rapid passage of such substances through the system, and to this he was not subjected.

*Spina bifida* in all its forms is an analogous vice of conformation on the dorsal surface of the body. In one case of total absence of the neuropophyses of all the vertebrae, the cord being only covered by a transparent theca, the mother convinced the writer that such cases may occur from their own state of mind during early gestation. She was a respectable person, but of a melancholy and desponding turn. She attributed the occurrence to having been disgusted by seeing one of her husband's pigs cut up, and having had the divided chine salted, and for some time hanging before her eyes in her sitting-room. The writer lately saw a remarkable case of this class in a living, but certainly almost moribund, infant, a few days old. The spine itself was perfect, but the parietal and frontal bones were absent, and at the top of the head was an oval tumour, consisting of the cerebrum and cerebellum, covered by the membranes, having some fluid under them. The eyes were closed and tumid, and were found, when their lids were opened, to have their axes everted. The child sucked the finger, cried, and moved all the limbs, but was livid and cold. Convulsive movements of the extensors, rather than the flexors, took place on irritating or pressing the tumour; and occasionally, when one side was pressed, the opposite half of the body would be convulsed. In another case the anterior part of the brain protruded under the form of two or three lengthened tumours from an opening in the frontal bone. Cases of the unnatural union of parts appear less common than those of non-union. A young man presented himself to the writer, in whom an irregular fusion occurred in the toes

and fingers of all his extremities; in one hand the index-finger and the thumb were fused into one, rather a thumb than a finger, opposable, and the nail somewhat double, and fortunately the use of the hand not much impaired; from the inner edge of one foot, between the tarsus and metatarsus, proceeded a great-toe or rather thumb, as it could be opposed to the other toes, much like the hind thumb of a quadrumanous animal; its bones were formed by those of the three larger toes, and its size was remarkable.

This was removed by amputation, the rest of the foot being strong and well able to support the body, or perhaps the unnatural toe might have been restored to a better position.

It is considered difficult to effect the cure of webbed fingers by dividing the intervening membrane, there being a strong tendency to reunion as the parts heal. The writer has succeeded, without the least trouble, by partially separating a narrow slip of integument from the dorsal surface of the first joints of the fingers, at the termination of the incision, the slip being long enough to stitch down to the palmar extremity of the incision. It will be found that the implantation of this will prevent all tendency to re-union.

There is a peculiarity of the hand in some individuals, probably rare, but which may escape notice. In a neighbour, Mr. S., there is an entire deficiency of one row of phalanges in both hands. Each finger has but two phalanges, the nails are as usual. The thumb has two phalanges, but the proximal one is very short. It would appear that it is not the distal phalanges of the fingers which are absent. This peculiarity is present in Mr. S.'s father, and affected also his grandfather, but his only son, more like his mother in features, has escaped it.

An instance of the birth of twins, joined like the Siamese brothers, occurred in a neighbouring village; both had hare-lip. Another full-grown infant appeared destitute of a neck, the head growing directly from the top of the thorax, but there was the usual number of cervical vertebrae; the cutis was hard and shagreened.

#### PRACTICE OF MEDICINE AND SURGERY.

#### THE HOSPITAL FOR DISEASES OF THE SKIN.

#### REPORT ON THE NATURAL HISTORY, DIAGNOSIS, AND TREATMENT OF ALOPECIA CIRCUMSCRIPTA.

(Continued from page 100.)

Upon the facts furnished in the table of cases given at page 100 the following propositions may be based:—

1. That a disease of the scalp occurs with some frequency in English practice, which may be defined as "Complete Baldness in circumscribed patches," and for which the designation of "Alopecia circumscripta" is an appropriate name.
2. That in extreme cases this disease may involve the entire scalp, and even the eyebrows, face, and chin, but that in these there is always a clear history of its having begun in well-defined patches.
3. That it is occasionally attended by a looseness and thinning of the hair on the scalp generally, there being, however, in these cases invariably some well-defined patches of complete baldness.
4. That it is *ab initio* quite distinct from all other diseases of the scalp, although it may in certain (very exceptional) cases appear as a sequel to one or other of the eruptive affections.
5. That it is very much more frequent in young persons than in adults.
6. That it is of nearly equal frequency in the two sexes.
7. That it affects the subjects of different temperaments in numbers which are probably about proportionate.
8. That it is totally incapable of spreading by contagion.
9. That its patches never exhibit either vesicles, pustules, or scurf, and that they are not usually attended by itching or other altered sensation.

10. That its anatomical characters are wasting of the hair bulbs and thinning of the affected parts of the scalp.
11. That it is not of parasitic origin, and that there is reason for believing that it generally acknowledges a constitutional cause.
12. That it is not met with, however, sufficiently often in connexion with any particular group of constitutional symptoms to justify us in considering it as consequent on any peculiar form of cachexia.
13. That it is occasionally liable to relapse after cure, but that the bald patches rarely show any disposition to change of place.
14. That it is of extremely chronic nature.

We shall proceed *seriatim* to examine these several propositions, and the nature of the evidence by which they are supported.

**PROPOSITION I.**—*That a disease of the scalp occurs with some frequency in English practice, which may be defined as "Complete Baldness in circumscribed patches," and for which the designation of "Alopecia circumscripta" is an appropriate name.*

The fact that forty-two examples of the disease have been placed on record in detail, must be deemed to fully establish the first part of this proposition. Although, as we have seen, denied by Cazenave and Schedel, it is admitted by Willan, Wilson, and Jenner, all of whom have given accurate descriptions of the disease. With regard to its rate of frequency, it must be borne in mind that the Hospital at which these cases were collected is a special one. Alopecia circumscripta is certainly not common in general practice. During the last four years it has occurred in the writer's practice at the Metropolitan Free Hospital about once in every 1500 cases, and there is probably no reason for thinking that these numbers do not indicate very fairly its average frequency.

With regard to name, the one mentioned seems by far the most applicable of those suggested. It accurately describes the condition which constitutes the one symptom of the disease. To the name of "Porriño decalvans" given by Willan, is the objection that the disease has no similarity to the true Porriño, and to that of "Accidental alopecia," proposed by Wilson, it may be objected that the first epithet is almost meaningless, and that as far as it has meaning is likely to mislead.

**PROPOSITION II.**—*That in extreme cases this disease may involve the entire scalp, and even the eyebrows, face, and chin, but that in these there is always a clear history of its having begun in well-defined patches.*

Case 26 is the only example in the list of the eyebrows and whiskers being destroyed, and in it the preceding headache, etc. had been unusually severe. The patient was the oldest in the list. The writer has never known it remove the hair from the pubes or axilla. A large majority of its male subjects are, it must be remembered, too young for the growth of whiskers or beard. Two of the cases in the list exemplify the loss of the eyebrows, and in several the entire scalp was bald. It would appear that the eyebrows, etc. are never destroyed, until the whole scalp has first been denuded. In all the cases the process had been one of more or less gradual spreading from several points, the alopecia having in the first instance involved only circumscribed portions of the scalp. This history, which is always a clear one, will always be a sufficient clue to the diagnosis from other forms of baldness. Difficulty in diagnosis can, however, but very rarely occur, as baldness in young people, excepting as the consequence of the disease under consideration, is almost never seen.

**PROPOSITION III.**—*That it is occasionally attended by a looseness and thinning of the hair on the scalp generally, there being, however, in these cases invariably some well-defined patches of complete baldness.*

Although in a few cases in the table the patients stated that their hair generally was loose and falling out, yet this is decidedly an unusual symptom. In a great majority the hair on the non-affected parts is abundant, and as firmly rooted as ever. Often within half-an-inch of the margins of the patches hairs may be found having large plump bulbs, and in a state of perfect nutrition. Even in those cases in which the falling of the hair generally is the most marked, the margins of the patches, which are completely bald, are always sufficiently marked to make the diagnosis easy.

**PROPOSITION IV.**—*That it is ab initio quite distinct from all other diseases of the scalp, although it may in certain (very*

*exceptional) cases appear as a sequel to one or other of the eruptive affections.*

Cazenave and Schedel have asserted that it is usually a consequent on some other scalp-disease, as true ringworm, contagious porriño, etc. and several other dermatologists have lent their support to the opinion. That it is not so in English practice, and that, on the contrary, Alopecia circumscripta is a perfectly distinct affection, is quite certain. Of the forty-two cases under examination, although in all careful inquiry was made on this matter, yet in only two was there any history of an eruption having preceded it. Cases 23 and 28 are the exceptional ones. In the first the patient, a young woman of 20, stated that she had had ringworm in infancy, and that her hair had never grown perfectly since. Her alopecia had, however, only existed for seven years, so that it did not seem to have been very directly connected with the preceding disease. In Case 28 what was termed a "scald head" was stated to have immediately preceded the alopecia. In all the other cases the patients or their friends stated positively that the patches had been smooth from the very first, and without the slightest of eruption.

**PROPOSITION V.**—*That it is very much more frequent in young persons than in adults.*

Of the forty-two cases the average age of the patients was 14 years, the youngest being 4 and the oldest 41. Eleven, or rather more than a fourth, had attained the 20th year. Of these, however, it must be remembered that the majority had been affected with it for several years: thus, in Case 2, the patient being 30, the disease had existed 6 years; in Case 23, the patient being 20, it had existed 7 years; and in Cases 28, 34, and 37, the ages being respectively 23, 25, and 23, the duration of the disease had been 16, 8, and 3 years. The number in which it commenced at a pre-adult period is thus reduced to a very small one.

**PROPOSITION VI.**—*That it is of nearly equal frequency in the two sexes.*

The proportions in the sexes are, of males 19, of females 23. With numbers so nearly equal, we are not authorized in believing that there is any real difference in the relative liability of the sexes.

**PROPOSITION VII.**—*That it affects the subjects of different temperaments in numbers which are probably about proportionate.*

In the absence of any standard of comparison as to the relative proportions of the different temperaments in the London population, this proposition must be stated with much caution. Of the cases in the series no note as to colour of hair and eyes, etc. was taken in six. Of the 34 in which these features were observed, we find that 10 were dark, having black or dark brown hair and eyes; 8 were of mixed temperament, having brown hair and grey or blue eyes; 8 were of fair complexion, having light hair and light grey or blue eyes; 5 had brown (hazel) hair and brown eyes; 2 had light brown hair and dark brown or black eyes; and 1 had red hair and grey eyes. One might perhaps suspect that, considering the comparative infrequency of the dark complexion in England, the number recorded as having black or very dark hair and eyes is disproportionately large. With this exception, the numbers are probably about what might have been expected, by those who have paid attention to these subjects, under the supposition that the disease affects indiscriminately those of all temperaments.

**PROPOSITION VIII.**—*That it is totally incapable of spreading by contagion.*

In Case 7, two sisters of the boy who was the patient had been affected with ringworm during the time (a year) that he had had alopecia. The patches in both of the sisters were stated to have been distinctly scaly, while those of their brother had been throughout smooth and glossy. There is therefore no reason for thinking this occurrence more than the accidental coincidence of two distinct diseases of the scalp affecting different members of the same family at the same time. In Cases 22 and 31 a sister in each was said to have contracted the disease by contagion from the patient. In neither of these, however, did the reputed recipient attend at the Hospital (although requested to do so), and no opportunity was afforded for ascertaining whether the disease did really exist. In both it was spoken of as having been very slight. Whenever, in the column which refers to contagion, we have used the phrase "much exposed," it is meant that the child living among its brothers and sisters had been placed under no restrictions, had slept with the others, used the same brushes,

combs, etc. Twenty-nine of the patients had thus most freely exposed themselves to the risk of communicating it to others, and in almost the whole of the remaining thirteen more or less of exposure had taken place. Yet in only the three just mentioned was there the slightest suspicion that any one had contracted it from them. The writer has never in any single instance seen two sisters, brothers, or playmates both suffering from alopecia. How different in these respects are the facts respecting the really contagious diseases of the scalp, porrigo and true ringworm! When we bear in mind that alopecia is a very lasting disease, and that the period of exposure had in most of our cases been very prolonged, we are surely supported by facts in the statement that it has no contagious properties.

**PROPOSITION IX.**—*That its patches never exhibit either vesicles, pustules, or scurf, and that these are not usually attended by itching or other altered sensation.*

In all cases the patient or his friends were closely questioned as to whether in any stage there had been noticed any scurfiness or moistness of the scalp. With the exception of Case No. 1, in which a very slight brawny condition had been observed, the history given was most clear that the patches had been perfectly smooth throughout. In 17 cases the patients stated that they had not the slightest itching or other altered sensation in the affected parts of the scalp; in ten there was slight itching, and in 1 it was said to be considerable; in 13 no note on this subject was preserved.

JONATHAN HUTCHINSON.

(To be concluded.)

## THE ROYAL LONDON OPHTHALMIC HOSPITAL.

### REPORT OF OPERATIONS PERFORMED FROM JAN. 1st TO JAN. 31st, 1858.

By Dr. C. BADER, Registrar to the Hospital.

#### EYELIDS.

Two operations for entropium. In the one the eye-lashes were removed in the usual way, in the other the fibro-cartilage was grooved parallel to the palpebral edge, leaving the latter intact.

In a case (Mr. Poland's) in which the entropium on one side had been treated in the former, on the other side in the latter manner, the cornea corresponding to the lid whose entire edge had been preserved (fibro-cartilage grooved) had recovered its transparency, while the other remained opaque.

Removal of a hazelnut-sized tumour of the left upper lid. It was opened through the conjunctiva, and its contents allowed to escape. This tumour was consequent on an injury.

Another tumour (congenital) at the side of the left upper eyebrow of the size of a walnut, well defined and immovable, was dissected out by Mr. Wordsworth. Its pedicle reached beneath the zygomatic arch; it was firmly adherent to the periosteum, and contained sebaceous matter.

Two cases of injury by lime producing adhesions of the palpebral to the ocular conjunctiva.

In the one case the adhesions were divided with scissors, and their reunion prevented by the frequent introduction of a probe. In the other case in the left eye, the whole of the palpebral edges were adherent to the globe and the cornea, exposed to the air, covered by dry cuticle of a grey colour. The adhesions were divided with scissors so as to admit of an artificial eye, which the patient at present wears with great comfort. In the right eye the adhesions were only partial, admitting the tears and imperfectly covering the cornea, which was transparent at the upper part. The non-adherent portion of the upper lid was inverted. The eye-lashes were dissected off, and by a second operation the adhesions separated with scissors, the outer canthus enlarged to admit a speculum, and an artificial pupil made opposite the transparent part of the cornea; the adhesions re-formed in spite of many attempts to prevent it. The patient, when the lid is drawn upwards, can count fingers as he could before these operations.

#### LACHRYMAL SAC.

Three cases of purulent discharge from the lachrymal sac, treated with the actual cautery.

In one case in which both sacs have been cauterized, the

discharge has reappeared on one side (on which there is diseased bone); Mr. Bowman's No. 6 probe is now passed every third day, and the case is improving.

#### PTERYGIUM.

Three cases of pterygium advancing upon the cornea, each treated differently. One was entirely dissected off; the second was dissected from before backwards beyond its corneal portion, and its apex, then moveable, attached by sutures to an incision in the conjunctiva near the upper and inner edge of the cornea. In the third case (Mr. Bowman's) its corneal portion was left, and that covering the sclerotic removed. The conjunctiva above and below was then made more moveable by lateral incisions, and brought together with sutures.

The three cases have remained well as yet. In the last case it was interesting to notice the disappearance of the portion left on the cornea. It gradually smoothed down and became transparent after the interruption of the blood supply.

#### STRABISMUS.

Eleven cases of internal strabismus operated upon sub-conjunctivally, most of them being severe cases; both internal recti were divided.

In two cases there was external strabismus while the patients were under the influence of the anæsthetic, but slight internal strabismus returned when the effect of the chloroform had passed off.

In several cases in which the defective vision remained after the operation it was elucidated by an ophthalmoscopic examination.

In a case of divergent strabismus, both external recti were divided after the old method.

#### CORNEA.

In a case in which the upper part of the cornea was leucomatous and protruding, its lower part transparent, it was proposed to excise an oval piece out of the leucomatous portion, and extract the lens. On opening the cornea no lens could be found, and one-third of the vitreous humour having escaped, the operation was discontinued; three weeks later the corneal section had healed, and the patient had perception of light as before the operation.

In a case of lead deposit on the cornea opposite the pupil, the deposit was scraped off with the convex edge of a knife. The cornea has during three weeks remained transparent.

#### IRIS.

Case of removal of a small piece of steel from the upper portion of the iris. The piece had entered the eye eighteen months previously; after a month the consequent inflammation subsided, vision being unimpaired. Fourteen days before he came to the Hospital dimness, pain, and other inflammatory symptoms appeared. The cornea was, when he applied, transparent, and the pupil active, excepting next to a small black point in the substance of the iris, midway between the pupillary and corneal edges. Mr. Dixon made an incision in the edge of the cornea nearest the black point, and seizing it with the iris forceps, extracted a black triangular hard body, which proved to be a piece of iron surrounded by organised lymph.

After three weeks the inflammatory symptoms had disappeared, and the patient had recovered good vision.

One case of acute, and two cases of chronic, glaucoma, treated by excision of a portion of iris in either eye.

The acute case completely recovered, with capillary hæmorrhage: the two chronic cases are improving.

In cases in which the operation has been successfully performed, the aqueous humour is not accumulated in the anterior chamber, but appears to escape through the wound as it is secreted. No active inflammatory symptoms have occurred during the after treatment, as one would expect after so severe an operation.

Three cases of the formation of an artificial pupil, in which the pupillary margin was adherent to a corneal cicatrix, and the iris drawn in folds in the same direction; in each of them the broad needle was advanced through the corneal edge to the point of adhesion, then thrust through the iris, and on withdrawing the needle the iris wound enlarged. One case of formation of an artificial pupil in both eyes, the whole circumference of both pupils being adherent to the capsule. The patient could not see to read. The broad-needle was introduced from the outer edge of the cornea, making the opening large enough to admit the canula forceps; then the iris was seized near its pupillary adhesion, and a small piece withdrawn

and snipped off. (Mr. White Cooper's operation;) the patient (Mr. Bowman's), left the Hospital the fifth day after the operation, and reads any type with either eye.

Four cases of detachment of pupillary adhesions to the lens capsule; the instruments used were the broad needle and cataract spatula. In one case the patient, who before the operation could see, but not read large letters, was able to read small type a week after the operation, which had been performed three weeks after the active symptoms of iritis had subsided. In another case, the patient, who was not able to read before the operation, could do so afterwards. Two of the cases were not improved by the operation.

One case of severe inflammation of the globe, in which part of the cornea was infiltrated with pus, and portions of its surface ulcerated, was treated by Mr. Critchett by opening the cornea near its outer and lower edge, so as to admit the canula forceps, and withdrew a piece of iris which was then left in the corneal wound. Ten days later all inflammatory symptoms had subsided, the cornea had become smooth, and no purulent infiltration was perceptible. The case is still under treatment for eversion of the lachrymal puncta, for which the posterior lip of the slit-up lachrymal ducts was removed (by Mr. Critchett), so as to offer an easier access to the tears.

#### CRYSTALLINE LENS.

One case of double, and two cases of extraction on one eye. In the double extraction, prolapse of the right iris occurred, and was therefore removed with scissors the eleventh day after the operation. This and one of the other cases left the Hospital, and in three weeks were able to read with either eye. One case, in which there had been chronic bronchitis, disease of the bicuspid valves, and a considerable arcus senilis, left the tenth day after the operation, and reads with the eye operated on. The corneal section had been made in the portion occupied by the arcus senilis. In another case of double extraction there was external strabismus, and no perception of light in the left eye, but a faint perception of light in the other. Adhesions of both pupils to an opaque membrane in the area; there had never been acute inflammatory symptoms. The pupil, fixed by the adhesions, offered considerable resistance to the escape of the lenses, which had to be taken out with the sharp hook. In the right eye the iris was almost in contact with the cornea, and slightly wounded on completing the section. No bleeding ensued. The patient left the Hospital the third week after the operation, with no perception of light on the left, and perception of large objects on the right eye.

Four cases of linear extraction. In two of them in which cataract existed, both eyes were operated on at the same time. Two were congenital, one traumatic, and the other three soft cataracts of spontaneous origin. The patients were of ages between 16 and 35. The operation consisted in breaking up the lens with one needle, enlarging the corneal puncture with the broad needle, and scooping out the broken-up lens substance. Mr. Bowman remarked that the small needle, while breaking up the lens, ought to retain the aqueous, and that it ought to be introduced obliquely at the corneal edge, there being less liability of wounding the posterior capsule on sudden movements of the eye. The cases remained in the Hospital from one to three weeks. One of the eyes (of one of the double linear extraction cases) was lost by ophthalmitis. The atropine had not been used, and leeches were applied too late. Atropine ought to be employed daily, and leeches applied whenever sickness or slight pain in the eye came on. With the other eyes operated on the patients could see to read on leaving the Hospital.

Three cases of false membrane behind the pupil. In one (after extraction) the false membrane was opened out with one needle, in the second (after ophthalmitis) it was removed with the canula forceps, in the third (the traumatic case) it was broken up with two needles, and the shreds removed with the scoop.

In simple extraction cases, adhesions of the pupil to the capsule are frequently found as the sole indicators of an inflammation, which might lead some to suppose a wound of the iris to have occurred during extraction.

It sometimes happens in opening out false membranes behind the pupil, that the vitreous advances, producing a very

satisfactory looking black pupil; in many of these cases the vitreous recedes again, the gap becomes covered by a membranous exudation, and keeps the aqueous and vitreous humour separate. This is, apparently, the most favourable result, since in most of the cases where it had not receded, a continuous ciliary irritation existed, though vision may have appeared more complete at the time. These interesting cases are under observation.

#### EXCISION OF THE GLOVE.

The operation has been performed in its usual way in five cases. One case of staphyomatous enlargement of the globe after purulent ophthalmia; one case of strumous deposit into the ciliary processes, with perforation of the sclerotic; one case of injury of the one eye, keeping up sympathetic suffering of the other eye; one case of general inflammation of the globe consequent upon injury, and one case of what appeared to be strumous deposit behind the crystalline lens; in the last case (a patient of Mr. Streetfield) the cornea and crystalline lens were transparent, and behind the lens a bright yellow, non-vascular mass was perceptible; a section of this eye proves the yellow appearance to be caused by the detached hyaloid and retina being intimately adherent to the posterior lens capsule. It is not often the case that the cornea and lens retain their transparency when the posterior parts of the eye are thus changed.

Total of major operations, 71.

### HOSPITAL NOTES.

#### CITRATE OF IRON AND STRYCHNIA A NEW THERAPEUTIC AGENT.

For a long time back a therapeutic agent of very efficient properties has been used with considerable success at the Royal Free Hospital in cases of dyspepsia of an atonic character by Dr. O'Connor. He has also found it productive of great benefit in similar conditions depending on functional derangement of the uterus. In these cases it acts as an emmenagogue when all other remedies have failed, and it has a powerful effect in tranquillizing the excitement of the nervous system. This preparation is a citrate of iron and strychnia, the dose of which is about 3 grains three times a-day, to be taken immediately after a meal. There is now a case of chorea in the Hospital under the care of Dr. O'Connor, immediately brought on by the patient being frightened by a thunderstorm in August last, since which time she has, without any intermission of the symptoms, been a sufferer. In this case the citrate of iron and strychnia has been only used for a few days, and already with marked benefit. The case is one of interest, and we purpose at a future time giving it in detail. The preparation which Dr. O'Connor uses is made by Mr. Bstick, of Brook-street, Grosvenor-square.

### NOTES AND QUERIES.

*Be that questioner much shall learn much.—Bacon.*

#### NO. 228.—AN EPISCOPAL APOTHECARY.

What authority is there for the statement, that Richard Fitz-Nigel, Bishop of London, A.D. 1198, was apothecary to Henry II.?

Bath.

INQUIRER.

**PRICE OF EMBALMING.**—A rich landholder recently died at Paris leaving a very large fortune. M. F. who was desired by the heir to embalm the body, made a charge of 2000 francs (£80) for the operation. This the heir resisted as exorbitant, stating that the usual price was 500 francs, but offering 1000. This being refused, an action was brought, and the Tribunal decided that the 1000 francs were sufficient, and condemned M. F. in the costs.

SATURDAY, FEBRUARY 27.

## POSITION AND PROSPECTS OF MEDICAL REFORM.

CONTINUING the remarks on Medical Reform from our Number of Feb. 6, we purpose to give a short account of the measures recently proposed to secure an Act of Parliament "to alter and amend the Laws relating to the Medical Profession," and therefore proceed to review the events of the past eighteen months bearing upon this subject; to look to the sources whence the measures of Medical reform have had their origin; to observe the circumstances which have influenced the progress of those measures, and which have tended to frustrate the endeavours of the active agents in these movements.

About the beginning of November, 1856, "the Bill of the Corporations" made its appearance. This Bill was the result of negotiations between the *Medical Bodies Corporate of England, Scotland, and Ireland*. The Colleges of Surgeons in each of the three kingdoms determined to agree on the following points, namely, (1.) Equality of qualification. (2.) Reciprocity of rights. (3.) Authoritative registration. In this bold determination they sought and obtained the co-operation of the Colleges of Physicians of England, the Faculty of Physicians and Surgeons of Glasgow, and the Society of Apothecaries of London. These Medical Corporations of the three kingdoms sent delegates, who repeatedly met, and ultimately opened communications with the Universities. Thus far they ostensibly appeared desirous to come to a harmonious adjustment of their respective rights and claims. But the prospect which opened up before this heterogeneous community began to appear much too suicidal. No doubt a Bill was framed, which from its inefficiency bore sufficient evidence of concession and compromise; but the concessions were not such as would benefit the public, and the vested rights of ancient corporations were not to be so quietly confiscated, nor the interests of Universities to be thus silently given up.

Hitherto the voice of the MEDICAL POPULATION of Great Britain and Ireland does not appear to have influenced proceedings in the least. But towards the end of November 1856 the general Medical population attempted to obtain a hearing in the matter. With feeble voice they made the praiseworthy effort to introduce more fully an element to represent the Medical Public in the Bill of the Corporations. This improvement was attempted to be effected by the British Medical Association. A deputation from the Medical Reform Committee of this Association, headed by Sir Charles Hastings, had an interview with Mr. Cowper, the then President of the Board of Health. This deputation represented, that while the Association Committee approved of certain portions of the proposed Bill, they urged the necessity of introducing the representative system more fully into the measures of Medical

Reform. Difficulties, however, appeared to multiply; and no one knew better than Mr. Cowper how grave and conflicting were the interests involved in the questions at issue; and however favourably disposed Government might be to Medical Reform, they would not then undertake to bring forward any ministerial measure to regulate or amend the laws relating to the Medical Profession. Already Mr. Cowper, in return to an address of the Honourable the House of Commons, dated April 14, 1856, had returns from no fewer than twenty-one different qualifying Institutions in Great Britain and Ireland, in reply to specific questions proposed to each Institution by a Select Committee of the House of Commons to inquire into the complicated subject.

These "Returns" relative to "Medical Licences" were ordered to be printed July 17, 1856; and probably this movement on the part of the House of Commons, which elicited the materials for this document, provoked those resolutions on the part of the "Qualifying Institutions" to meet, agree, concede, and compromise, resulting in the measures we have just noticed. These printed returns occupy ninety-two pages of blue-book folio, and present this peculiar feature,—that to condense or classify the matter in reply is almost impossible, each of the twenty-one "Qualifying Institutions" differing from one another in one or more essential particulars; a fact highly suggestive of itself, and sufficiently pointing to the necessity of reducing the heterogeneous mass to a uniform whole, by some comprehensive Act of Parliament. The information conveyed by the "Returns" may, perhaps, be classified as follows:—

## I. STATISTICAL RETURNS, which show—

1. That there are no fewer than TWENTY-ONE different Medical Institutions in Great Britain and Ireland, each of which "Qualify" or grant Medical licences.

2. That there are NINE different designations under which legally-qualified Medical men may be designated, qualified, or licensed, by one or other of these Twenty-one Institutions.

3. These designations are as follow:—Bachelors of Medicine, Doctors of Medicine, Masters of Surgery, Licentiates in Medicine and Surgery, Extra Licentiates in Medicine, Licentiates in Midwifery, Fellows of Colleges, Members of Colleges, Surgeons. In addition to these may be enumerated "Holders of Letters Testimonial" granted by the College of Physicians of London; and also "Holders of Certificates of Fitness for the Army or the Navy."

4. Records appear to be kept by each Institution of the total number of "qualifications" they grant from time to time, and of the names of the persons to whom they are granted; but there are no universal or legally authentic records of the number and nature of the qualifications possessed by every legally qualified Medical man. The only record of this kind is the result of publishing enterprise, as evinced in the Medical Directory.

II. Under a second head might be arranged the "privileges which each of the so-called 'qualifications' are supposed to confer on its possessor." These privileges do not always appear to be clearly defined by the charter of the qualifying body; and it also appears that the privileges which attach to the same qualification (in name) are varied, as the charter of the Institution varies under which they are granted.

Regarding these privileges some general statements may be made. They may be arranged under the following heads:—

1. Legal rights conferred by charter very generally and indefinitely defined.

2. Rights established as legal by "use and wont."

3. Rights conferred by the local acts of Charitable and Municipal Institutions.

4. Exclusive legal rights and privileges pertaining to the Corporations and derived from various authorities.

Practically, therefore, and in virtue of these various kinds of rights and privileges, the Medical Profession, as at present existing, may be arranged into the following classes:—

ENGLAND.—1. *Physicians*, deriving this designation from the College of which they are a Fellow, or from the possession of a degree in Medicine conferred on them by a University.

2. *Apothecaries*, or General Practitioners, and those who possess the exclusive right to practise Pharmacy.

3. *Surgeons*, who are Members and sometimes Fellows of the College of Surgeons.

Of these, the most extensive rights and powers appear to be possessed by the Apothecary.

SCOTLAND.—1. *Physicians* holding their designations as in England.

2. *Surgeons and Apothecaries combined*, with exclusive privileges as regards practice in certain counties; and with general rights now recognised as legal by "*use and wont*."

3. *Physicians and Surgeons combined*, with exclusive rights as regards practice in certain counties; and with general chartered rights extending throughout the British dominions.

IRELAND.—Here there are also—

1. *Physicians*, but with exclusive rights as regards being Physicians to county infirmaries, and with dominion over Apothecaries.

2. *Apothecaries*, with rights similar to those in England.

3. *Surgeons*,—a designation or qualification *sui generis* as regards Ireland.

Now it further appears, that unless the "qualifications" designated as above are obtained from corporate bodies possessed of certain exclusive rights, the holders of many of these qualifications now mentioned are constantly liable to be checkmated by such corporate bodies as the Apothecaries' Society of England, the College of Physicians of England, the Apothecaries' Hall of Ireland, the College of Surgeons of Edinburgh, the Faculty of Physicians and Surgeons of Glasgow, and the King and Queen's Colleges of Physicians of Ireland.

To the Public all this is a mystery. The General Public cannot and do not understand these distinctions. Any one who chooses to profess and publicly to advertise that he is competent to treat and cure diseases, is considered by the public as a Medical man, and he passes under the general designation of a "*doctor*." To the young student of medicine also commencing his career, such nice distinctions are unknown, and in many instances their meaning is comprehended when it is too late. Such a diversity of interest and of qualification can be attended with none other than injurious results; and while it cherishes narrow-mindedness amongst the Medical population as a whole, it is a condition of existence obstructive to the advance of medicine as a science, and to the general public it is "a mockery, a delusion, and a snare."

### THE WEEK.

ANY one who has watched the efforts which the two large sister Universities of England have for some years past been making to adapt themselves to the requirements of the times in so far as real prudence will permit, will not be surprised to hear that a scheme has been contemplated by which an Oxford education and residence may be rendered more accessible to Medical students. In addition to what has already been effected by the opening of Fellowships and by grave alterations in the curricula of study and methods of testing the knowledge of graduates, it is known that the appliances of education in that place are being at the present time very largely increased by open scholarships of high value, of which several will be appropriated to natural science, and all acces-

sible to men of industry. The above changes will certainly attract many to the University of Oxford who otherwise would not go thither; but the proposal to which we mainly alluded as regards Medical students virtually is, that for them the term of residence should be reduced from three to two years, in consideration of the three years which they are afterwards required to spend at some recognised Hospital. This abridgement of time of residence will of course diminish the expense by at least one-third to the student, and in three of the halls in Oxford already the expense of living has been so far diminished that a student's total expenses may, if he choose, not exceed a hundred pounds a year. This diminution of expense, in addition to the much larger chance of acquiring scholarships of considerable worth, will no doubt be the means, (considering also the increased intellectual attractions as afforded by the new museums, collections, laboratories, and professorial lectures on subjects collateral and preparatory to surgery and medicine,) of drawing to the University many who otherwise would have entered the portals of the Profession by wasting their time in the mere mixing of drugs, and by a residence, somewhat hazardous, in London or some large bustling city. While on the subject of expense it ought to be stated that the Radcliffe Fellowships at Oxford will, it is believed, be converted into Medical studentships, and that at most, if not all of the Colleges, ordinary Fellowships are now tenable by Medical men, who of course will be eligible to the well endowed Professorial chairs. The project to which we have alluded emanates from a large number of Masters of Arts and Graduates in Medicine of Oxford, and was set on foot by a Fellow of Oriel, whose pamphlet we recommend to the perusal of all interested. Should the Hebdomadal Council see fit to effect the change asked for, Oxford, by the infusion of a comparatively new element into its character, will gain much, but the members of the Medical Profession will, if they avail themselves of these opportunities, gain still more.

In another column will be found a full account of the changes in the Army Medical Department proposed by the Royal Commissioners. It is not expected, however, that they will be carried into effect very soon. Probably the recent change of ministry may retard still further the adoption of the recommendations; but we trust no ill-timed economy may put off the issue of the warrant so necessary for the improvement of the pay and position of the officers of the Department.

The Master of the Newington Workhouse has been found guilty of the charges against him as to the illegal disposal of bodies for dissection. Sentence has been deferred, however, for the decision of some legal points urged in his favour. Mr. Shaddock, of Guy's Hospital, deposed that the gratuity system had been regularly worked in that Hospital since 1849. It is to be hoped that, under the new Inspector of Anatomy, the necessity for such bribery will cease. Mr. Hawkins has called a meeting of the Anatomical Teachers for this evening, and we trust that means will be devised for remedying the existing evils. The object to be kept in view is to maintain in London a supply of subjects as abundant and cheap as in Scotland or Ireland. This object ought to be attained, and neither teachers nor students in London should rest satisfied until it is attained.

The University of London received the New Charter on Wednesday. The effect of this charter upon national education is likely to be both great and good. Candidates for degrees will not for the future be called upon for certificates as to *where* or *how* they have acquired their knowledge. They will merely have to produce testimonials of age and good

character to entitle them to examination, and the examination passed, the degree must be conferred. This is a great step in advance. The day may come when the same principle will be recognised in Medical education, and teachers will then be stimulated to attract students by the value of their lectures, not by the facility with which they grant certificates of attendance on lectures students are compelled to attend before they are admitted to examination.

Unusual interest has been excited by this year's Gulstonian Lectures at the College of Physicians by Dr. Symonds of Clifton. The subject was "Headache," and the manner in which it was treated was so masterly that we are sure our readers will be glad to hear that the lectures will appear in these pages forthwith. We shall hope to see friends from the provinces lecturing at our Colleges more frequently than heretofore.

The trial of Mr. Monk, of Preston, for forging the will of a patient, has ended in his conviction. It is needless to say how much such dishonour of a member of our Profession is to be lamented. Nor need we add anything to the severe but just remarks of Mr. Baron Martin in passing sentence. He said, "You must perfectly well know that, but a very few years ago, so sure as you stand there a living man, so sure would you have been hanged for this offence. This crime of forging wills was the last from which that punishment was taken off, as men thought, from the circumstances which usually attended it, it was a worse crime than any other forgery. But your case is worse than a common one, because you are a Medical man, and men when sick must call in a Medical man; and if Medical men, instead of giving their professional services, should endeavour to get from the sick man his property, it would destroy all confidence in them. For the sake of the public, and of the Profession to which you belong, it is necessary to show Medical men that, if convicted of such an offence as you have been convicted of, they will receive the most severe punishment the law will permit. The sentence of the Court is, that you be imprisoned in penal servitude for life."

If the following statement in the "Emigrant's Guide to Canada" be correct, and we believe it to be so, it is quite clear either that only steamers must be chartered as emigrant ships, or that the sanitary condition of the sailing vessels must be ameliorated:—

"There has been very little sickness among the English, Irish and Scotch emigrants, the average mortality not having been more than one-third of one per cent., chiefly confined to children. The foreign passengers have suffered more; but among them the average mortality, between embarkation in Europe and landing in Quebec, has been less than one and  $\frac{1}{2}$  per cent., children included. The mortality at sea has been confined to the sailing ships; not a single death has been reported on board any of the steamers."

## CHANGES IN THE ARMY MEDICAL DEPARTMENT

RECOMMENDED BY  
THE ROYAL COMMISSION.

### EDUCATION OF THE ARMY MEDICAL OFFICER.

As regards the qualifications to be required of the candidates previous to examination, we recommend, that in all cases such certificate as would qualify a civilian to practise Medicine as well as Surgery should be exacted of the candidate, and that the examination should comprise some test of general education.

We further recommend, as regards both Surgical and

Medical knowledge, the addition of a practical to a theoretical examination.

That this examination be competitive, and be entrusted to a body of practised examiners, as is now done by the East India Company, and we think it desirable that, if possible, one and the same board should conduct the examination for the Medical Service of the East India Company, the Navy, and the Army.

That after the first examination, the candidates be sent to a military general Hospital, there to go through a course of instruction in military hygiene, and in clinical military Medicine and Surgery, for which purpose the necessary Professional chairs, in lieu of the two now existing in Edinburgh and Dublin, should be instituted at the principal general Hospital in England.

That during their residence at such general Hospital all the probationers be accommodated with quarters, and shall receive such rate of pay as may be sufficient for their subsistence. That the course shall not be less than six months previous to an examination on the subjects of the course, on passing which the probationers shall be eligible for appointments as Assistant-Surgeons, and that, if possible, their first appointment be to a regiment.

That an examination in the practical knowledge of his Profession as a military Medical officer be passed by the Assistant-Surgeon before promotion to a Surgeoncy.

That leave of absence be granted for attendance at Hospitals and Medical Schools.

That Medical officers be permitted to take private practice, under such regulations as may insure attention to military duties.

### PAY AND RETIREMENT.

We recommend that the regulation which requires officers of the department, when promoted, to serve for one or two years on a lower rate of pay than that to which from their length of service they are entitled, be abolished. We are of opinion that a considerable augmentation of the pay and retiring allowances, but especially of the former, is necessary to the interests of the service; but we must leave the adjustment of the details of pay of each rank to the Executive Government.

We are of opinion that the granting of a limited number of good service pensions to the officers most distinguished by their zeal and efficiency is due to the department, and will act as a wholesome stimulus to its officers.

We consider compulsory retirement at 65 years of age for the inspectorial ranks, and 55 years of age for the executive ranks, to be absolutely necessary for the efficiency of the service.

### PROMOTION, ROSTER OF SERVICE, AND RELATIVE RANK.

We recommend that the rank of first-class Staff-Surgeon be abolished, and that Regimental and Staff-Surgeons, now called Second-Class Staff-Surgeons, should, after twenty years' service, be styled Surgeon-Majors, with a small addition to their pay.

That the rule of seniority be strictly maintained in the promotion of Assistant-Surgeons to the rank of Surgeons, except in case of incompetency or misconduct; and that no exception be made to this rule save for distinguished conduct, when the services for the which the officer is promoted shall be published with his name in the *Gazette*.

That the seniority be that in the Army, without reference to the station on which the officer to be promoted may be serving. That promotion to the ranks of Deputy-Inspector and Inspector-General be by selection for merit; and that, in the recommendation to the Commander-in-Chief, the Director-General shall state the position on the Army List of the officer recommended and the grounds of the selection.

That any confidential report by which the character of an officer is unfavourably affected shall be always communicated to him, and an opportunity given him of offering his explanation in defence.

We recommend the establishment of a roster of service, subject to this condition, that the amplest discretion be vested in the Director-General, to select for each station the principal Medical officer whom he may think, from experience and character, likely best to discharge any peculiar duties which may attach to the Medical charge of that particular station.

That the relative rank of the Army Medical officers of dis-

tinguished merit be styled Honorary Physicians and Surgeons to your Majesty.

That the Army Medical Department be held entitled to the same share of honours and rewards as combatant officers of the same rank.

That in the Army List the Medical Department should have precedence of the Commissariat, and that their names should appear according to their rank, with the dates of their commissions, in the list of the regimental staff, and that the whole regimental staff be placed before the list of captains.

That a limited number of good-service pensions be granted to Medical officers of distinguished service.

Lastly, that new regulations as to pay and retirements, promotion, rank, honours, and rewards, be embodied in a Royal Warrant for the regulation of the Army Medical Department.

#### CONSTITUTION OF THE ARMY MEDICAL DEPARTMENT.

We recommend that the Director-General should have three colleagues associated with him, selected for their eminence in medical, sanitary, and statistical knowledge respectively, and to be appointed by the Secretary of State for War. These officers would act as the council of the Director-General, and should have the power of submitting any questions to the Board, and of expressing their opinions in writing. All matters of routine would be referred to the head of the branch to which they belong, and only such matters should be subjected to the consideration of the Council as are of importance. Minutes of all proceedings of the Council should be recorded by the Secretary, but the Director-General, acting upon his own responsibility, might disregard those opinions if he consider it necessary, recording his reasons for so doing. We recommend that the appointments on the Council of the Army Medical Department should be held for five years, subject to re-appointment at the termination of that period, if the interests of the public service should require it; and that a similar regulation should apply to the Director-General, a longer period, however, being fixed for the tenure of his office.

We feel it our duty strongly to recommend a revision of the salary now attached to the office of Director-General.

With a view to give immediate effect to these recommendations, we beg to suggest, in addition to the Commission to inspect the barracks and hospitals as already advised, the appointment of committees to draw up a scheme for the re-organization of the office of Director-General; to frame a draft warrant regulating promotion; to draw up a scheme for the proposed Medical School; to revise the regulations; and to arrange the basis and forms on which the statistics of disease and mortality of the army are henceforth to be collected and recorded.

#### REVIEWS.

*A Three Weeks' Scamper through the Spas of Germany and Belgium, with an Appendix on the Nature and Uses of Mineral Waters.* By ERASMUS WILSON, F.R.S. London: 1858. 8vo. pp. 368.

WHAT can equal the insatiable appetite for work of a London Doctor? Occupied month after month in sunless, smoky, foggy London, with mental and physical powers kept constantly on the verge of exhaustion, he snatches a short autumn holiday, and then, instead of indulging in the *dolce far niente*,—that pleasure which none can enjoy so thoroughly as the busy Londoner in a short interval of idleness, sunshine, and quiet—he keeps his eyes, ears, and note-book open, and his holiday results in the production of a new book. So Mr. Erasmus Wilson—one of the busiest of our busy brethren—who alleges in his preface “that he has not had a holiday before since he has been in practice,”—devotes his short autumn excursion to authorship, and his three weeks' scamper in Germany and Belgium leads to the work before us on the spas of those countries.

As may be anticipated from the title, the book must not be regarded, in a scientific point of view, as any rival of the many excellent works extant on mineral waters, nor has it that charm to the general reader which has made the “Bubbles from the Brunnens,” and the “Autumn near the Rhine,” so deservedly “household books.” But a very readable ac-

count of a Medical holiday it certainly is. Mr. Wilson looks at everything with the eye of a London doctor, and writes with the pen of a smart lively member of the fraternity. So we commend his book to those who wish to know a little more than they do now of Spa, Aix-la-Chapelle, Ems, Schwalbach, Wiesbaden, Homburg, Kissingen, Kreuznach, and a good many other places visited by their patients; and who are willing to pick up their information, not by expending the midnight oil, but by utilizing an idle hour in the carriage, or by the fire-side in arm-chair and slippers. Let Mr. Wilson's account of the carbonic acid baths at Lungen Schwalbach stand as a specimen of his book, and of our appreciation of it. Here is the account:

“There are few things on the earth more enjoyable than a residence under water in one of these baths for half-an-hour. I speak from experience of this delight, having philosophised tranquilly on the matter for that term of life one morning shortly after dinner. The temperature, as prescribed me by the bath-woman, was 86° Fah., and I had no reason to differ from her in opinion as to the result. The bath just holds sufficient water to cover you completely; lying at full length, with the back of your head resting on the edge, you fold your arms, and compose yourself to peace. The position of your head gives you a view of yourself through the green-looking, transparent water; and your first observation is one of admiration of the extreme whiteness and fairness of your skin, and you are reminded of the naïve expression of admiration of the Frenchman, who said, with regard to a neighbouring bath, that ‘on devient amoureux de soi-même.’ Next you are struck by the appearance of what seems to be a copious eruption breaking out over the whole skin; but an eruption of an unusual kind, an eruption, in fact, of glittering pearls; and then the adhesiveness of the pearls is remarkable; you cannot shake them off, but you must wipe them off with a sweep in order to come to your white skin once again, and they collect again as fast as ever. But, as you are prohibited from moving while in the bath, and as your own sensations soon tell you that you are chilled by motion, but feel warm and comfortable under this novel costume of pearls, you are fain to leave them alone. But this is not all; your bath is not a silent one; it is a musical bath; and while you are thus amusing your eye, firstly, with the charms of your own skin, and then with the sparkling vest of pearls that quickly clothes it, your ear is gratified by a little talkative wick! wick! wick! wick! wick! wick! wick! wick! wick! and when you turn to look after the little fellows that are treating you to a pigmy concert on the surface of the water, and begin to fancy yourself a Gulliver, in one of the seas of the Lilliputians, there is a round-mouthed chuckle close to your ear, which makes you afraid that the Lilliputians have, since settling accounts with Gulliver, hired an army of stronger fellows to fight their battles in case of need; and then, dear me! your mind is relieved from anxiety by finding that the wick! wicks! are only little playful gas-bubbles that are cracking their jokes and their sides also, on the surface of the bath, and that the more noisy laughing fellows are only bubbles of a larger growth, that slip out from under your back, or from the hollow of your armpits. My half-hour soon slipped away, and if his Royal Highness of Clarence took pleasure in his bath of Malmsey, I also enjoyed my bath of the water-wine of Schwalbach. It is here that the old grow young and the weak strong; while calm, tranquillity, and ease, envelope as in a mantle the charmed and soothed senses.”—Pp. 119—121.

*On Squinting, Paralytic Affections of the Eye, and certain forms of impaired Vision.* By CARSTEN HOLTHOUSE, F.R.C.S.E., Surgeon to the Westminster Hospital, and to the South London Ophthalmic Hospital. London: 1858. Pp. 210.

THE principal portion of this work is devoted to the subject of strabismus and its treatment. Mr. Holthouse very truly remarks, that although the importance of dividing the muscles of the eyeballs for the cure of this affection is generally recognised, and the operation itself has been very frequently performed, yet the theory of the deformity is not yet fully understood, nor are the results of the treatment uniformly successful. One very manifest cause of failure in this operation is the uncertainty often existing as to which eye ought to be operated upon; and although it may be admitted that the worse eye ought to be chosen, yet it is not by any means easy

to determine which is the worse, and, under the most careful guidance, a second operation sometimes becomes necessary. In cases of confirmed squint, the division of the shortened muscle is the only measure which can avail in removing the defect; and the plan of dividing it beneath the conjunctiva is preferred, and we think very properly, by Mr. Holthouse; for by this method the air is excluded from the wound, and the risk of inflammation is avoided, while the adjoining parts are but little disturbed from their normal state. In certain cases, however, the ordinary operation is to be preferred to the subconjunctival one; as in those in which the eye is immovably fixed in the outer or inner canthus, or in which its lateral movements are so limited, that it cannot be brought beyond the centre of the orbit. "In all such cases," says Mr. Holthouse, "the mere division of the shortened muscle is not sufficient, and the conjunctiva and subconjunctival fascia require to be freely divided, and even dissected somewhat from the sclerotic before the eye can be brought into a central position." Mr. Holthouse's remarks are all thoroughly practical, and throw much light upon an important department of ophthalmic surgery.

*A Theoretical and Practical Treatise on Midwifery, including the Diseases of Pregnancy and Parturition, and the Attentions required by the Child from Birth to the period of Weaning.* By P. CAZEAUX. Second American, translated from the fifth French edition, by W. R. BULLOCK, M.D. With 140 Illustrations. Philadelphia: 1857. 8vo. pp. 992.

THE book of Cazeaux is adopted in France by the Superior Council of Public Instruction, and is placed, by ministerial decision, among the classical works designed for the use of students in midwifery in the Maternity Hospital of Paris. The translation of Dr. Bullock is remarkably well done, and the illustrations, though very inferior to those of Rambotham, are numerous and useful. We can recommend this work to those specially interested in the subjects treated, and can especially recommend the American edition.

*A Practical Treatise on the Diseases of Children.* By J. FORSTER MEIGS, M.D. Third Edition. Philadelphia: 1858. 8vo. pp. 724.

It would be difficult to find an American work in any department of practical medicine calculated to give a more favourable impression of the results of the labours of our transatlantic brethren than this edition of Dr. Meigs's book. It contains a great store of valuable information well arranged. It would be unjust to pass over this work and Dr. Bullock's translation of Cazeaux without a word of praise to Messrs. Lindsay and Blakiston of Philadelphia for the manner in which the books are "got up." The paper is good, type excellent, and the binding extremely strong and serviceable.

## PROGRESS OF MEDICAL SCIENCE.

### Selections from Foreign Journals.

#### ON THE TREATMENT OF INTERMITTENT FEVER.

By M. NONAT.

In a recent clinical lecture at La Charité, M. Nonat made some observations upon the treatment of intermittent fever. He observed that in judging of the value of febrifuges the real point to observe is not the relief of the febrile manifestation but of the splenic engorgement, for as long as the latter remains the cure is only temporary. Now, as the result of his trial of the numerous febrifuges which have been proposed as substitutes for cinchona, he finds that they all fail in influencing this condition of the spleen. Even arsenic itself must be placed in the same category of imperfect remedies, the sulphate of quinine being the only complete and reliable one, though the sulphate of cinchonine and the cinchona itself are so in a lesser degree only. To obtain all the effects from the quinine, however, its administration must be methodical. When paroxysms are present it should be given at the commencement of the pyrexia, beginning with a dose large in proportion to the splenic complication, and only gradually diminishing this. The continuance of the medicine too

must be regulated by the diminution of the spleen. When the fever is simple, and without splenic engorgement, five or six grains in the day are sufficient. Supposing that the disease is of old standing, and that the spleen is much increased in size, then, during seven or eight days 22 grains, in two doses, are given daily, and afterwards for other five days 15 grains in one dose daily. The quantity is then gradually diminished to 7, 6, and 5 grains, the patient being instructed to continue doses of 1 or 2 grains for some time after this. When there is great splenic swelling, and especially when accompanied by pain in the hypochondrium, M. Nonat orders leeches or cupping, bringing the economy first under the influence of the quinine by employing it for three days prior to the depletion. Since this combined treatment has been put into force he has not found old cases of two, three, or four years' standing offer resistance. The grand point is to employ the quinine in large enough doses, and to continue it until the engorgement of the spleen has become completely dissipated.—*Union Méd.* 1857, No. 109.

#### ON THE VARIATIONS OF THE COLOUR OF VENOUS BLOOD.

By Professor CLAUDE BERNARD.

From the period of the discovery of the circulation, two descriptions of blood have been recognised; the one red or arterial, the other black or venous; and so characteristic has this difference in colour of the arterial and venous blood been considered, that it has served since the time of Bichat for the anatomical division of the circulatory organs. The facts now about to be mentioned will prove that henceforth we cannot regard as synonyms the terms venous and black blood; some venous blood being found, in the normal condition, as red as arterial, and what is more, sometimes red and sometimes black. But what will most interest the physiologist is to learn that these variations in the colour of venous blood correspond to different determinate functional conditions of the organs.

As long since as 1845, M. Bernard, while experimenting upon dogs on the eliminatory power of the kidney, was surprised at finding that the blood which left that organ by the vein was as red as that which entered it by the artery. Latterly, he has resumed the investigation of the subject at the College of France. The same phenomenon that had formerly been observed in the dog presented itself in the rabbit, and the red blood of the renal veins arriving and visibly mingling with the black blood of the vena cava inferior. The lumbar veins, on the other hand, discharged black blood very near the renal veins, as did also a small muscular vein which opened into the left renal vein. On multiplying the experiments, and varying the condition of the observation, it was soon found that the usual red colour of the blood of the renal vein might change in shade, and, under the influence of certain circumstances, become completely black. Thus, contradiction would take place if we were contented with the announcement of a single observation. This may unfortunately be almost always the case in physiology, when we fail to distinguish amidst such complex phenomena, the eminently variable conditions which every living organism presents.

Having exhibited the two possible appearances of the blood of the renal veins, the next point was to examine what relation they held to the performance of the function of the kidney. To this end there was placed in the ureter a small silver tube, by which the urine was observed to flow drop by drop, almost continuously, as it is known to do. It was then found that the blood of the renal vein, as well as the tissue of the kidney, continued completely red as long as the urine flowed abundantly by the tube; but that this flow ceased to take place under the influence of circumstances which, while they rendered the blood of the renal vein black, gave at the same time a bluish tint to the kidney itself. Hence it would seem that the red colour of the blood of the renal vein was referrible to the functional activity of the kidney, and its black colour to the condition of repose or cessation of function. Moreover, it was found that the nature of the reaction of the urine excited no influence on the phenomenon; the blood of the renal vein being alike red in the dog with acid urine and in the rabbit whose urine is alkaline during digestion and acid after twenty-four or thirty-six hours of abstinence.

Without enumerating the various influences that are capable of disturbing the secretion of the urine, and leading to a

change in the colour of the blood of the renal vein, the author contents himself with adverting to the perturbation that may ensue from the mode of operating. If it is desired to observe the red colour of the venous blood, the abdomen must not be largely opened and the intestines displaced, for then suppression of urine will almost immediately ensue, and the blood in the vein will often become as black as that of the vena cava. A small opening should be made in the lumbar region, and especially on the left side, the left renal vein being more easily exposed in consequence of its greater length. Through the same wound the ureter may afterwards be isolated, so as to introduce the silver tube, in order to make certain whether during observation the function of the kidney continues to be carried on or not.

From what has been said it clearly results that the blood of this vein, presenting habitually a red colour in connexion with the formation of urine, which is almost continuous, does not correspond with the definition of venous blood already given. The first question that presents itself to the mind is whether this is an isolated fact, special to the kidney, or whether it may be extended to the secretory organs, whose function is, in like manner, the separation of a special organic fluid in their tissue. The submaxillary gland of the dog offers great facilities by its superficial and isolated position for the investigation of this point; the numerous anatomical varieties which its vein exhibits in nowise interfering with the observation of the physiological phenomena. In the first experiment the blood it contained was found as completely black as the darkest venous blood; but this arose from the fact of the secretion by the gland, which is intermittent, not then being active. When, however, some drops of vinegar were instilled into the mouth of the animal, which by its reflex action induced the secretory activity of the gland, the blood gradually but rapidly exchanged the black for the red colour, the black colour being again restored when the secretion had ceased. In order to render the interpretation of the phenomenon yet more positive, a small silver tube was introduced into the exposed excretory canal of the gland, and the nervous branch of the lingual nerve going to the gland was isolated. It was then found that as long as the organ remained in repose nothing passed by the tube, and black blood passed through the vein; while, whenever the nerve of the gland was excited by galvanism, and secretion was produced, the colour of the blood became red, regaining its black colour when the secretion was arrested after the cessation of the stimulation. The trial was made several times, and with similar results. There was always an interval of some seconds elapsed between the production or the cessation of the stimulus and the changes of colour in the blood, as if the gland required a short period for the discharge of the blood it already contained. Moreover, it was observed that the blood flowed always more abundantly when red, that is, during the state of functional activity of the organ, than when black, the organs being then in a state of repose.

These two series of results obtained from the kidney and the submaxillary gland certainly do not constitute isolated facts; and the same observation should doubtless be extended to other glands. The investigations as yet made by the author on the parotid and on the glands of the alimentary canal have furnished similar general results; but the study of the subject will only be complete when each particular gland shall have been experimented on.

"It results from the facts now stated, that if in the physiological condition we may still designate arterial blood as the red blood, the appellation of black blood cannot in this general manner be conferred on venous blood. We have seen, in fact, that the venous blood may be found red or black in secretory organs, accordingly as these are observed in a state of activity or repose. This consideration of the activity and repose of the organ, which correspond in some degree to its statical and dynamical conditions, appears to me to be an important point for introduction into the chemical and physiological study of the blood. In fact, it is not alone by its colour that the venous blood of an organ at rest differs from the venous blood of an organ in activity; but it presents also other important differential characters, which must depend upon a profound difference of the chemical constitution. Thus the venous blood of the kidney performing its function, which is red, is more diffuent, and sometimes even presents no coagulum; while the blood of the same vein, when the kidney has ceased to act, becomes black, and presents a consistent coagulum, etc. Without doubt physiologists and che-

mists have already learned that venous blood cannot, like arterial blood, be everywhere regarded as identical, and that it is necessary to analyse the venous blood of each organ in particular; but what, I believe, has never yet been stated, and which, nevertheless, seems to me indispensably necessary to be henceforth considered, if we desire that chemical analyses should prove as useful as possible to physiology, is the separate and comparative examination of the composition of the venous blood of the same organ when in repose and in activity. From what has been stated above, we may predict that there will be often found greater differences between the two bloods of the same organ in the state of activity and of repose than between the corresponding bloods of two different organs. This point of view is not solely applicable to glands, but should be extended to all the organs of the body, the venous blood of which will now have to be studied under these two conditions. We may in some measure characterise each tissue by the very different modifications its functional activity impresses on the blood that traverses it. Thus, if the blood quits glands when active reddened, it leaves a muscle that contracts with a very black colour and different physical characters. The mechanism of these different colorations of the blood will necessarily receive its explanation through ulterior chemical analyses, of which we are only at present desirous of indicating the physiological conditions. We will conclude with the remark, that all these modifications which supervene in the blood as a consequence of the functional activity of organs are always determined by the nervous system. It is consequently at this point of contact between the organic tissues and the blood that we must acquire our ideas of the special part played by the nervous system in the physico-chemical phenomena of life. The development of the facts which relate to this point of general physiology will form the subject of an early communication."—*Comptes Rendus*, tom. xli. pp. 159—166.

#### EXCERPTA MINORA.

*Glycerine in Dysentery.*—M. Daudé, a French provincial practitioner, reports that during a severe epidemic of dysentery he found the employment of glycerine of the greatest utility. He prescribed 1 ounce of glycerine in five ounces of decoction of linseed, in an injection, repeated twice a day, and two spoonfuls every hour of the following mixture:—Glycerine 11 drachms, orange-flower water and water equal parts, so as to make a five ounce mixture.—*Union Méd.* 1857, No. 140.

*New form of Actual Caustery.*—M. Bonnafond, who is strongly persuaded of the excellence of the actual caustery as a means of treatment, has endeavoured to obviate some of the inconveniences of its application. To this end he has invented the following caustic, which burns slowly, and admirably replaces the actual caustery when the cauterisation is not required to act very deeply, or to be made on a very wet surface. Dissolve 5 parts of gum tragacanth in a sufficiency of water, facilitating the solution by adding a little sugar, and rendering it as concentrated as possible. Then add gradually 15 parts of vegetable charcoal, and 2 of nitrate of potass, and thus form a homogeneous paste capable of being rolled into cylinders of various sizes. These must be well dried, and when wanted for use may be lighted either by a candle or the fire. The eschar is usually detached in five or six days. Latterly, M. Bonnafond has used a mixture of the gum and charcoal without the potass.—*Ibid.* No. 143.

*Boutigny's Fumigating Powder.*—B. Potass. bisulph., pot. nitr. aa. perox. manganese, q.s. to blacken the mixture. Each substance is to be roughly powdered, and then carefully mixed with each other. A shovel, brick, etc., is to be heated to a commencing red heat, and the powder thrown upon it. After the fumigation is over M. Boutigny burns a small leaf of paper which disengages a most agreeable odour. It is prepared by dissolving 1 part of nitrate of potass, and 2 of sugar in 6 of water, into which unsized paper is dipped, and then allowed to dry.—*Gaz. des Hôp.* 1858, No. 15.

*Vaccinating with a Magnetised Needle.*—Professor Beka states that since 1856 hundreds of children have been thus vaccinated, with scarcely any failures occurring. The point of the needle is well saturated with the magnetic fluid before practising the vaccinations, which are then performed in the usual manner, a single magnetisation serving for many vaccinations. It is quite surprising to observe the rapidity with which the vaccine virus is absorbed when the needle is thus prepared, *Presse Méd. Belge*, No. 7.

## FOREIGN CORRESPONDENCE.

## FRANCE.

PARIS, Feb. 20, 1858.

IN the recent discussion on Parasitism at the Académie de Médecine, Professor Bouley mentioned some interesting facts. Professor Trousseau had said that parasites are much more easily developed, and that their number increases much quicker in weak individuals than in strong and healthy ones. Professor Bouley mentions many facts in support of this view. For instance, the itch in sheep is extremely disastrous in years of bad crops. The same thing exists for the various parasites of the dog and horse, and for the entozoa as well as for external parasites. M. Delafond has shown that on a healthy sheep it was possible to put a great number of acari on the skin without communicating the itch; while, on the contrary, the development of the cutaneous affection was rapid, if the same animal had been weakened by a bad regimen. The conclusion from the facts mentioned by Messrs. Trousseau and Bouley is, that in cases of the existence of internal or external parasites it is extremely important to employ a tonic regimen.

A very serious question was discussed yesterday at the Société de Biologie. M. Raciborsky has published a paper, in which he maintains that the dysmenorrhœal membrane is always a part or the whole of the mucous membrane of the uterus, and that it comes out only in cases of pregnancy. M. Ch. Robin accepts almost completely these views, and he affirms that he has constantly found the villi indicating the beginning of the transformation of the mucous membrane of the uterus in the dysmenorrhœal membranes he has examined. M. Cazeaux, on the contrary, thinks that a great reserve is necessary in this question. He doubts, in the first place, that the expelled membranes are always parts of the mucous covering of the uterine cavity; and in the second place, he has seen portions of this covering expelled by girls, whom he thinks were positively virgins. M. Blot concurs with M. Cazeaux. He has seen parts of the mucous membrane of the uterus that had been expelled, and which had not the least appearance of the characters that this membrane acquires during pregnancy.
